The mucoperichondrial membrane on either side of the quadrangular cartilage is elevated in a fashion not unlike the method in vogue for elevating the flaps in a submucous resection, from before backward (Fig 4). The mucoperichondrial membrane is elevated proximally three cm on one side and two cm on the other side of the quadrangular cartilage, upward to the dorsum of the septum, as required in Fig 2, and to the level of the lower border of the hanging nasal tip in Fig 1, and downward to the nasal floor. This is facilitated by the use of retractors which keep the original incision open, and expose the deeper structures (Fig 4).

The next step is to make two parallel incisions in the mucoperichondrium of the nasal septum by way of the nares, from before backwards, beginning at the lower margin of the septum and proceeding backwards a distance of three cm. Thus, the distance between the two parallel incisions are identical to the portions of the mucoperichondrium undermined (Fig 5).

The two parallel incisions are next united by a third incision, which is vertical and connects their posterior ends, giving the completed incision the appearance of a rectangular minus the anterior line (Fig 5). These three incisions are repeated on the opposite side of the septum, but here the parallel incisions are

only extended as far back as two cm.

The columella is thus liberated and freed of its attachment and may easily be lowered to the desired position. The columella is anchored in position by two mattress sutures at the lower end of the quadrangular cartilage through the septum mobile (Fig 6). Three mattress sutures are placed in the septal membrane flap at the posterior ends of the parallel incisions and through the septal cartilage (Fig 6). The columella incision is closed with interrupted horse-hair sutures.

Upon completion of the operation, an area of septal cartilage, denuded of its mucoperichondrial covering, will be seen on either side of the nasal septum due to the sliding of the previously made membranous flaps downwards, thereby lengthening the septum mobile.

These denuded areas do not occur at the same level on either side of the septum. As it is not desirable to completely deprive the septum of its nutrition, which comes from its perichondrial covering, this is accomplished by undermining the septal flaps two cm on one side of the septum and three cm on the other side. The exposed areas of the septal cartilage heal nicely by granulation followed by smooth scarring (Fig 6).

The operation may also be performed entirely intranasally. If this approach is used, only the three united incisions in the mucoperichondrium on either side of the septum are made, and the flaps are elevated downward from behind forward as far as the lower border of the quadrangular cartilage (Fig 7), on both sides of the septum.

The rest of the procedure is the same as described for the external route. The intranasal method is of value only in abolishing the external columella scar. The procedure, I feel, is greatly facilitated through the external approach, and the subsequent columella scar is nil.

1049 PARK AVE.

The venereal disease control program is "going over the top." If the ethical physicians don't add venereal disease services to their list of regular services, the quacks

and incompetents will be doing the cashing-in while the public pays and suffers.

NOMA

VINCENT I BONAFEDE, M D, *Sonyea*

A case of noma is reported because the condition, though long known, is always interesting both as to cause and course. This infection is also known as cancrum oris and gangrenous ulcerative stomatitis. It may be described as an acute fulminating and progressive gangrenous erosive ulcer involving the oral cavity and contiguous tissues. Its occurrence is rare but it is most commonly seen in undernourished and debilitated individuals as (a) a sequel to infectious diseases, principally measles and typhoid,¹ (b) associated with blood dyscrasias as leukemia² and obscure anemia,³ (c) sequel to focal oral infection following extraction of teeth,⁴ or trauma to the buccal mucosa, (d) sequel to chronic enteritis,⁵ (e) sequel to puerperal infection,⁶ and spontaneously without evidence of any underlying disease.⁷

It affects all age groups but according to Cecil, it is most frequent in children from two to five years of age. Benedict and Berger reported unusual spontaneous cases arising in a newborn child and an infant sixteen months of age respectively, without any clinical evidence of underlying disease. The etiology is not definitely known although many investigators believe it is due to bacterial synergism. Mixed infection is common with *Spirochetes* and the fusiform bacilli evident as the prominent invaders. Hicken⁸ demonstrated experimental and clinical evidence to substantiate the theory of bacterial synergism. The course is usually rapid and, according to Cecil, death intervenes from five to ten days after the onset from some terminal infection as bronchopneumonia, lung abscess, sepsis, etc. Recovery is the exception and then only with horrible unsightly defects. Treatment is significantly inefficacious, the common oxidizing solutions, the arsenicals, various dyes and antiseptics, fuming nitric acid, undiluted formalin, x-ray and radical excision with cautery have all been tried with equally poor results. Excision and cautery appears, nevertheless, to be the single, most effective therapeutic agent, if performed early

Case Report

R. E., a white boy, eighteen years of age, was admitted to Craig Colony on May 11, 1933, for custodial care and treatment for epilepsy. Relevant personal history revealed the onset of generalized convulsions at one year of age and the childhood diseases—measles, mumps, and rickets. On admission he was undernourished and showed poor development. Weight 130 pounds, height 5 feet 9¾ inches. Significant physical findings disclosed a deformity of the chest, apparently due to rickets, and a severe suppurative infection of the gums of long-standing showing deep pockets extending into the alveolar processes. Smears showed numerous *Spirochetes* and fusiform bacilli. The patient responded to treatment with the use of the ordinary oxidizing agents (sodium perborate, hydrogen peroxide), a power spray, and intravenous sulpharsphenamine.

On August 16, he was placed in bed with a reactivated infection of the gums, an ischio-rectal abscess, and loose stools. His progress was steadily downward with de-

Fig 1

hydration, marked loss of weight, and emaciation despite treatment to which he was frequently uncooperative and resistive. Beginning November 13, pustular infections of the right ear, right shoulder, and right arm appeared. On November 27, at 5 00 A M the patient pried four loose teeth out of his mouth with a spoon and the next day the gums about the self-extracted maxillary incisors became swollen, black, and gangrenous. The contiguous buccal mucosa of the upper lip was swollen. By November 29, the gangrene had spread rapidly by direct extension in all directions, involved the hard palate, and perforated the central portion of the upper lip to the outside, producing an antrum in the upper lip. The odor was extremely offensive and pain was significantly absent. The regional lymphatics were not involved. On November 30, the gangrenous ulceration had completely eroded the entire upper lip, the anterior third of the hard palate, and began to destroy the nasal alae, the contiguous tissues of the face about the angles of the mouth, and the anterior third of the tongue. On December 1, the destructive process in-

volved the right central portion of the lower lip and began to perforate through the lower lip. Death occurred exactly five days after onset. (The attached photograph, Fig 1, was postmortem) The temperature and pulse were not marked, the former ranging from 97 to 100° F (axillary), the latter varying from 80 to 108 min. Respirations were from twenty to twenty-four per minute. Smears were loaded with *B fusiformis* and *Spirocheti vincenti*. Other laboratory work was dispensed with. Necropsy was refused.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, D R P H, New York City

Editorial Note Under this title will appear short summaries of 'transition cases' from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Marital Longings

Ruth, twenty-six, is married two years with a man eight years her senior. She has never become pregnant, although no anti-conceptional method has been used. He is a writer, engrossed in his job and is mostly overworked and tired.

"He is busy, very busy," she says. "I admire him, because he is learned, well-read and extremely devoted to his work. He is a great man. But I am unhappy. I take no part in his activities. I am not interested in them. He does not desire the sex intercourse, but has it for my sake. It would be better he never had it. It is a torture. He says, 'Let me sleep a while, I am so tired, but you keep awake.' When he opens his eyes he begins to bother me, soon to give up and get very angry, probably at himself. Sometimes he is so funny, I cannot help laughing and when I go to hear him lecture, which I rarely do, I must laugh as I think of his antics in bed. I blush and run out of the hall from among his audience and I laugh outside. It's terrible. I wish I were

not married. I'd never give a thought to such things. But now I keep on thinking about them. In the middle of the day, when I am alone, I have all sorts of visions. I stretch out my arms and I embrace the void. I sit down and wait silently, without the least motion, so as not to disturb the dream, the expectation of a caress. A breeze passing lightly over my arm—like this—thrills me. Because he never pets me, never embraces, never kisses. He is a great man, but is it my fault?"

At the examination there is no sign of her ever having had a real contact. She is virginal. It seems she has only been tortured, tantalized. Husband does not understand her at all. He believes she is angry or crying out of sheer "foolishness." "Women's eyes are in a wet place, says a proverb in my country," he explains.

The result? Moments of rage, suicidal intentions which become more and more threatening, inactivity, inability to do her work, alternating with brooding, depressive days in which she refuses to eat, to dress or to go out of bed.

The remedy? Several talks with him explaining the true situation which she would never reveal to him, making him change his program of work, opening his eyes to a possible danger, and treatment of his partial impotence. On the other hand, making her understand that she must be patient

with him, she must avoid humiliating and discouraging him. Both are advised to sleep in separate beds in ordinary times.

She is asked to return to the occupation she had as a girl, so as not to be idle. All this effects a cure within one year.

A Useful Experiment

A married woman with four children, still good looking and only thirty-one years of age, was sent by her husband on vacation. She took only one child along, the youngest, and stayed in a popular summer resort for a month. Originally she refused to go altogether. She was a drudge and feared the furniture would be spoiled in her absence and somebody, not a guest, might go into the parlor. She agreed to be away two weeks, but her intention was to come back within a few days. However, while there, something strange happened that made her ask her husband to allow her another week and then another week. Most of the vacationists were women, but there were a few men also and one of them, although over fifty and a grandfather, made love to her. That was something new to this serious, overworked, matter-of-fact woman. She had heard about such events, but relegated them to novels and even there she thought they referred to young, unmarried persons only. Her husband had never pronounced the word "love"—not even between their betrothal and wedding. To be sure, her seducer was a regular Don Juan and few women resisted him. But at the time our heroine was so amazed and thrilled as to be blind and deaf to anything except to the divine talk, and charming and delightful gestures of this poetical and superbly mannered gentleman who deigned to take her into his confidence and speak to her in such a beautiful way about his heartaches. She was dazed and in her impatience to walk with him late into the night on the lonely forest paths scarcely lit by mysterious moonlight patches, she lost her sleep and forgot to eat. She was a fairy hardly touching the ground and living on some higher spheres.

But what a rude awakening! What a plunge into the common-place home of her prosaic husband at her return to the city! She tried to overcome her feelings but could not. After she had rubbed her eyes, she saw only one thing: her guilt. Then she fell into a bottomless depression and wept day and night, without being able to gather enough will-power to do the smallest part of her work. She felt low and filthy while her husband's equanimity made him grow to the proportions of an angel. How could she face him? How will she ever deserve him?

That was the condition in which she came to this examiner. Persevering interrogation brought out, not only the foregoing description of her short blissful deliverance from her everyday life, with many unmentionable details, but also the dreary facts of her married years.

Her husband was a "nice man," a "good provider," although mean enough not to put into her hands more money than absolutely necessary. The small house which he had acquired and in which they were living, was in his own name. He regarded her as an immature child and never told her anything about his plans or business.

"He never trusts me with anything, but I always have what I need," she said. "He never showed any affection to me or to the children. He is probably the most perfect man, exhibiting neither anger nor kindness. His face is like a mask, it rarely changes. I am sure he cannot be swayed into sinning like myself. He is superhuman. He speaks little and says what he ought to. At the best joke, when everybody sheds tears from laughter, he has but the faintest smile. His sex relations are satisfactory, but there is neither more nor less than that. He just has intercourse, there is no caressing."

This formidable husband was summoned to our office and we had a heart-to-heart talk, during which the entire situation was explained to him. When he heard of his wife's *faux-pas* and the contrast between the love-faker's miraculous, enticing, and transforming powers and his own plain, direct, but dry devices, he was dumbfounded—and he understood. Nay, he actually cried and admitted that he loved his wife, although he had never told her and had never thought that love was more than mere possession.

That evening he brought her a present and kissed her, though without words. From then on he wooed her constantly in his own dumb way. He only informed her that he knew about her adventure and that he "pardoned" her. She had to go through this superficial love-making in the country resort in order to appreciate his deeper partnership, he said, and he promised to treat her differently in the future.

Incidentally, she was cured and became happier than she had ever been.

hydration, marked loss of weight, and emaciation despite treatment to which he was frequently uncooperative and resistive. Beginning November 13, pustular infections of the right ear, right shoulder, and right arm appeared. On November 27, at 5 00 A M the patient pried four loose teeth out of his mouth with a spoon and the next day the gums about the self-extracted maxillary incisors became swollen, black, and gangrenous. The result? Moments of rage, suicidal intentions which become more and more threatening, inactivity, inability to do her work, alternating with brooding, depressive days in which she refuses to eat, to dress or to go out of bed.

usurping prerogatives without which private practice cannot exist

There are other common grounds besides similar troubles. The physician and lawyer must work together in a wide variety of cases. A better understanding on the part of each of the other's problems and the proper approach to them would facilitate and strengthen inter-professional relations.

When it comes to legislation, the legal profession has opportunities which medicine does not enjoy. Many lawyers hold legislative seats. The physician-legislator is a rarity. This spring legal opposition helped to kill a physicians' lien act, where cooperation between the two professions could have eliminated objectionable features and secured the enactment of a just, wisely framed law.

There are many ways in which medicine and the law, through closer collaboration, could be of service to the public and each other. A number of county medical societies try to further this end by holding at least one meeting a year in conjunction with their local bar.

Determining Activity of Infectious Foci

The relationship of certain systemic disorders to foci of infection is an established fact. Nevertheless, in an individual instance it is sometimes extremely difficult to detect the focus and still more difficult to determine whether or not it is the active cause. Especially in the vicinity of the dental roots, areas of infection may be present without having any connection with the rest of the system. These would therefore not act as the source of a general disease.

To differentiate between an active and an inactive dental focus has hitherto not been possible since neither clinical nor roentgenological examination affords such qualitative differentiation. Gutzeit and Küchlin¹ propose a means whereby the

recognition of an offending focus about the dental roots becomes possible. Small electrodes (two to three cm.) are applied on the buccal and lingual sides of the tooth and the roots are subjected to short waves. Where the focus is active, the sedimentation rate of the erythrocytes is accelerated from two to four hours. Such a finding is not present when an inactive focus is irradiated with short waves.

If verified by further study, this will go far toward preventing the blind removal of suspected foci and eliminate unnecessary surgery to the dental apparatus. Furthermore, if this method is applicable to infections about the teeth, there is reason to believe that it should work equally as well with the tonsils, sinuses, gall-bladder, etc. The positive recognition of active foci would overcome the principle objection of the more cautious physician against radical removal of foci of infection.

Estrogenic Therapy of Acne

The relationship of acne vulgaris to the onset of puberty in the preponderance of cases makes it apparent that at least one cause of this condition is an endocrine imbalance. More than two-thirds of all cases of acne had their onset between the twelfth and fourteenth year. Sixty per cent of the females studied showed some aberration of menstrual function.¹

Rosenthal² estimated the estrogenic substance in the blood and urine of women suffering from acne vulgaris and in ninety-three per cent of cases found this substance to be absent or greatly diminished in the blood. A similar result was obtained in the urine estimations in eighty-two per cent. From this, he concluded that an abnormality in the formation or utilization of the sex hormones entered into the pathogenesis of acne.

Responsibility for Public Health

In a recent address before a Conference of Health Officers and Public Health Nurses, Dr Charles H Goodrich, President of the Medical Society of the State of New York, accepted for the profession the slogan, "Every Physician a Deputy Health Officer." He was free to accept this challenge for, by ancient tradition, physicians have always considered themselves responsible for the public health.

Unfortunately, many principles long accepted in theory lag in the translation into fact. The periodic health examination is a striking example. For two decades and more, the prophylactic examination has enjoyed universal approval. Nevertheless, few patients demand this service, and let us admit it, few physicians have troubled to perfect themselves in the technic of the complete preventive health study.

There is little doubt that more intensive cooperation between health departments and the private practitioner would be beneficial to community finances as well as community health. Unnecessary sickness levies a high economic toll on the nation each year.

For the utmost in such collaboration to

be achieved, public health departments must show great respect for the economic rights of the profession. Every community has indeed a vital stake in the prosperity of its physicians, as Dr Frederic E Elhott has declared.

Under the Vaughn plan, the city of Detroit has come closer than any other American community to realizing the slogan, "Every Physician a Deputy Health Officer." Its increased outlay for professional services has paid dividends in health and money. President Goodrich makes a practical approach to an important problem when he suggests that representatives of the New York State Health Department and profession make a joint study of the Detroit system on the scene.

Medicine and the Law

In many respects the legal profession today faces a situation as critical as that confronting medicine. Like physicians, lawyers see the ethics and economic stability of their profession undermined by overcrowding in urban areas and undesirable competitive practices which follow in its wake. Also like physicians, they see governmental and commercial agencies invading their domain and

THE MEDICAL GRIEVANCE COMMITTEE

1926-1937

HAROLD RYPINS, M D, F A C P, *Albany*
Executive Secretary

Unique in its organization, powers, and functions, the Medical Grievance Committee of the State of New York is the only statutory, quasi-judicial tribunal created solely to hear and determine charges against licensed physicians and to recommend discipline in cases of guilt. In all other states, disciplinary action is lodged in the State Board of Medical Examiners. Under the New York law, examining for medical licensure and the disciplining licensed practitioners are completely separated, examinations are conducted by the State Board of Medical Examiners and disciplinary proceedings by the Medical Grievance Committee. Both licensure and revocation of licenses are vested in the Board of Regents.

The members of the Grievance Committee, ten in number, are appointed by the Board of Regents for five-year terms—four members are appointed from nominations made by the Medical Society of the State of New York, two members from nominations by the New York State Homeopathic Society, one member from nominations by the New York State Osteopathic Society, and three members of conspicuous professional standing are appointed by the Regents upon their own nomination. The Committee serves without compensation. The members of the Committee are

Orrin Sage Wightman, M D, *Chairman*
Arthur B Van Loon, M D, *Secretary*
Frederick H. Flaherty, M D
Austin G Morris, M D
Roy Upham, M D
Martin B Tinker, M D
Moses Keschner, M D
Walter A. Merkley, D O
J Richard Kevin, M D
Vincent P Mazzola, M D

The Secretary of the State Board of Medical Examiners is the Executive Secretary of the Grievance Committee.

The members of the Committee are public officers. They pass upon the sufficiency of charges, hear evidence, rule on objections to testimony, pass on motions, and make decisions—just as in a court of law.

They have legal authority to administer oaths, to subpoena, and to make rules and regulations for the conduct of their business.

To fully comprehend the work and limitations of the Grievance Committee, it is necessary to understand its specific statutory powers and its administrative relationships with (1) The Board of Regents, (2) The Assistant Attorneys-General, and (3) The Secretary of the Board of Medical Examiners, which may be compared to the relations between (1) A trial court, (2) An appellate or reviewing court, (3) The district attorney, and (4) The police commissioner.

As a trial court the Grievance Committee exercises two distinct jurisdictions. In the first instance, the Committee, after charges are duly preferred, determines whether or not the facts alleged are sufficient to warrant a statutory trial, termed by the Committee a "formal" trial. Frequently a preliminary or informal hearing is held either by the Committee or a subcommittee to pass upon the sufficiency *prima facie* of the charges or a complaint or evidence supporting same. This is similar to a hearing before a Magistrate to determine whether or not the facts produced against a defendant are *prima facie* sufficient to constitute a crime and to warrant holding the defendant for further action. If the Committee determines that the facts charged warrant a formal trial, the charges are then referred for trial to a subcommittee. Thus, the Committee combines within itself two quasi-judicial functions which in criminal proceedings are distinct, namely, those of a Magistrate and those of a trial Court.

The subcommittees, consisting of three members or more of the Committee, are appointed by the Chairman. At least one member of a subcommittee designated to hear charges must represent the same school of practice as the accused physician. The subcommittee hearing at a trial of formal charges is always constituted differently from the subcommittee which has previously determined that a trial on charges is necessary.

Based on findings such as these, Lawrence supplemented the usual treatment of this skin disorder by the administration of Antuitrin-S and obtained a maximum benefit in from twelve to sixteen weeks. Boys responded equally as well as girls did. The usual dosage is one to two c.c. every other day for the early weeks of treatment, and should then be decreased as the improvement becomes evident. Recurrences of acne vulgaris, it would seem respond equally well when estrogenic therapy is resumed. This medication should be supplemented by the standard local measures employed for the superimposed infection present in acne.

CURRENT COMMENT

"REGIMENTATION, STANDARDIZATION et al, is the revered Juggernaut before and beneath which all true Americanism must be crushed!"

"Health of the country has suddenly become a paramount issue. Hunger, seemingly, has not. Yet it was lack of bread that sent the last of the Bourbons to the tumbril. Pre-revolutionary France never carried the load of tax-eaters borne by tax-paying martyrs as does the United States today."

"May we remind the profession that 'there are none so deaf as those that will not hear, and none so blind as those who will not see?'"—Strong words and a reminder from the editors of the *Illinois Medical Journal* of August 1937.

"THE ADMINISTRATION OF MEDICAL welfare service is at once the most neglected and the most vitally important problem facing organized medicine today. Leaders of the profession have spent a great deal of time and energy in speculating, viewing with alarm, and wringing their hands over the alleged imminence of some undefined phenomenon called 'state medicine,' as though it were a system as yet unborn which will appear some fine morning at our window full grown overnight, after the manner of Jack's beanstalk."

"The naivete of this conception, and the functional myopia it has produced in the

face of the real and growing presence of state medicine has been the subject of editorial comment here and there,—but while the anxious skippers of many medical societies have been apprehensively scanning the horizon for the battle fleets of state medicine, a whole school of submarines has popped up, one by one just off the bow, and for several years they have been busily pumping torpedoes into the ship—not without effect.

"These submarines of whose attacks we have been too proud or too preoccupied to take account, are of course the precedents and policies of medical welfare administration, local, state and national, and when that which we shall be able to recognize as state medicine comes steaming over the horizon, its advance guard of submarines will have so riddled our proud ship with compromises and concessions that one clean hit from the big fellow may sink us."—From a recent issue of the *Westchester Medical Bulletin*.

"LOW-COST HOUSING UNDER this bill will be impossible in any large city in America"—A regretful but perhaps true comment on the Wagner-Steagall Slum Clearance Bill by Langdon W. Post, chairman of the New York City Housing Authority, and one of the original bill's chief backers.

"IT IS ABSURD FOR THINKING WOMEN to sit silently by while doctors and legislators, priests and preachers fuss and squabble over a law which has primarily to do with us"—A female of the species speaks her mind on the question of birth control, and is quoted in *The Digest* under date of August 14.

"THE THREAT OF SOCIALIZATION has been effective, too, in awakening the physician's sense of social responsibility. Conversely, it has stimulated the interest of the public in medical problems."

"Thus, in these and other ways, the road has been paved for a better understanding between the doctor and doctored in the future."

"Who can deny the adage that blessings often come in disguise?"—One way of looking at it, as voiced by *Medical Economics*, August 1937.

The undertaker's very smart,
He'll never need the dole,
For he gets rich when other folks
Are going in the hole. —Exchange

The statute specifies and limits the causes for which a physician may be disciplined as follows

(a) That the physician is guilty of fraud or deceit in the practice of medicine or in his admission to the practice of medicine

(b) That a physician has been convicted in a court of competent jurisdiction, either within or without this state, of a crime or misdemeanor, or

(c) That a physician is an habitual drunkard, or addicted to the use of morphine, cocaine or other drugs having similar effect, or has become insane, or

(d) That a physician is guilty of untrue, fraudulent, misleading or deceptive advertising, or advertising that he can cure or treat disease by a secret method, procedure, treatment or medicine or that he can treat, operate, and prescribe for any human condition by a method, means or procedure which he refuses to divulge upon demand to the committee on grievances, or

(e) That a physician did undertake or engage in any manner or by any ways or means whatsoever to procure or to perform any criminal abortion or to violate section eleven hundred and forty-two of the penal law

In addition, the statute provides that in the case of a physician convicted of a felony, the Board of Regents may revoke the physician's license. In such cases a hearing before the Grievance Committee is not necessary as the effect of a felony conviction of a physician is to revoke his license to practice medicine, should he practice medicine after conviction of a felony, he is guilty of a misdemeanor

The nature of the 591 complaints against licensed physicians for the period 1926-37 was as follows

Improper or misleading advertising	102
Performing or undertaking to perform abortions	69
Aiding and abetting an unlicensed practitioner	53
Ambulance chasing	16
Fraud and deceit	58
Malpractice	93
Unethical conduct	138
Narcotic violation	12
Insanity	1
Arbitration	3
Felony conviction	18
Misdemeanor conviction	2
Miscellaneous	26
Total	591

In view of the definite and strict limitations in the type of misconduct which the

law permits the Grievance Committee to try, the Committee has received and refused to hear, on the grounds of non-jurisdiction the following complaints

Malpractice and Negligence	79
Unethical conduct	106
Advertising (non-fraudulent)	72
Miscellaneous	19
Total	276

Of the five hundred and ninety-one complaints against physicians, three hundred and twenty-six could not be entertained for the reason that either (a) the complaint did not come within the statutory purview of the Committee, or (b) sufficient legal evidence was not available. One hundred and seventy cases were disposed of after informal hearing by subcommittees and thirteen after formal trials, where the evidence did not warrant disciplinary action. Fifty-three physicians have been found guilty by the Committee, resulting in the revocation by the Board of Regents of the licenses of thirty-two physicians, the suspension for periods varying from six months to two years of the licenses of nine physicians, and formal reprimand and censure of eleven physicians. In only one case did the Board of Regents reject the determination of the Grievance Committee.

The nature of the charges for which fifty-two physicians had their licenses revoked or suspended or were formally censured and reprimanded, as aforesaid is as follows

	Revoked	Suspended	Censured and Reprimanded
Misleading Advertising			1
Abortion	5	4	1
Aiding and Abetting	2	4	6
Fraud and Deceit	3	1	3
Narcotic Violation	3		
Insanity	1		
Felony Conviction	18		
	32	9	11

While the primary function of the Grievance Committee is to protect the public from unscrupulous and dishonest practitioners of medicine and by their elimination to raise the standards of practice in the medical profession, it has also served to protect a large number of ethical practitioners from unfounded litigation with its

On both a preliminary hearing and a formal trial, the accused physician has the right to appear with counsel and to cross-examine witnesses. A stenographic record of the testimony is kept and is transcribed at the conclusion of each hearing and trial. The Committee is not bound by the laws of evidence in the conduct of its proceedings, but its determination must be founded on sufficient legal evidence. Strict rules of procedure need not be followed.

From this recital, it appears that the Committee's function is fundamentally that of a trial court—a fact-finding tribunal—with power to recommend the discipline to be imposed. The law does not contemplate that it serve as an investigative commission or a prosecuting agency to secure evidence of misconduct on the part of physicians. It is not the duty of the Committee to prefer charges.

Under the statute, any person, corporation or public officer may prefer charges. The Department of Education may initiate proceedings in any case. In practice, complaints against physicians are brought before the Committee by letters, affidavits or charges filed with the Executive Secretary by aggrieved citizens, practicing physicians, district attorneys, police and other public officers. If the complaint clearly falls beyond the statutory powers of the Committee, to be discussed directly, the Executive Secretary, after consultation with the Assistant Attorney-General in charge, advises the complainant that the Grievance Committee has no jurisdiction over the complaint. Such action of the Executive Secretary is reported to the Committee for its approval. If the facts come within the statutory jurisdiction of the Committee, but the evidence is insufficient upon which to base a disciplinary proceeding, which is frequently the case, the Secretary of the Board of Medical Examiners, acting for the Education Department pursuant to its statutory power, rather than for the Grievance Committee, causes an independent investigation to be made through the staff of inspectors and special investigators employed by the Education Department for securing evidence of the illegal practice of medicine. In this capacity the Secretary carries out investigative functions and procedures comparable to that of a police commissioner. Like the Grievance Committee, he exercises dual functions which are en-

tirely distinct—*firstly*, in investigating and securing evidence of misconduct, *secondly*, as an executive officer appointed by the Committee.

Legal guidance is received by the Executive Secretary from two assistant attorneys-general, specially assigned by the Attorney-General to the Education Department. The Assistant Attorney-General attends all hearings and trials, presents the evidence in support of complaints or charges, cross-examines witnesses for the defense, and acts as counsel to the Committee.

When a physician has been found guilty of charges after trial, the subcommittee makes a report of its findings, determination, and recommendation to the full Grievance Committee. On the receipt of the report of the subcommittee, the Committee reviews the entire record. Only in the event that the Committee *unanimously* determines that the physician is guilty of the charges on their merits, may the determination of the Committee be reported to and acted upon by the Board of Regents. If the physician is unanimously found guilty by the Committee, the record, findings, determination, and recommendation of the Committee are forwarded to the Board of Regents who, after due hearing may " in their discretion execute an order accepting or modifying such determination of said committee.

" The theory of the law that the Board of Regents shall take final action in such matters is that the Regents grant to physicians power and authority, as evidenced by licenses, to practice medicine, and the Board that licenses is the Board to determine what action should be taken against a physician for violating the statutory conditions under which licenses were issued.

Should a physician so desire he may apply for a judicial review of the action of the Board of Regents in revoking or suspending his license or in censuring him. Such review may be had by the Appellate Division of the Supreme Court, Third Department, and the physician may apply for a stay of the execution of the order of the Regents on notice to the Attorney-General.

If the accused physician is found not guilty by the Committee, a dismissal of the charge is ordered and he may be relieved of any possible odium which may attach by reason of the charges against him. Public exoneration may be granted if requested by the accused.

PNEUMONIA CONTROL PROGRAM

Post-Graduate Educational Institutes in Pneumonia for the General Practitioner

The New York State Medical Society in collaboration with the Bureau of Pneumonia Control of the New York State Department of Health and in cooperation with some of the large medical school hospitals of the State is sponsoring a series of one-day institutes on "The Diagnosis and Treatment of Pneumonia" with special emphasis on serum therapy. These institutes will be held in the five academic centers of the State Albany, Buffalo, New York City, Rochester, and Syracuse, and will accommodate physicians in the counties surrounding these cities. The educational facilities of these institutes will be extended to the general practitioner who is desirous of learning more in detail about the recent advances in the diagnosis and treatment of pneumonia and who is anxious to familiarize himself with the exact technic of serum therapy.

Each institute will accommodate fifty physicians in the counties surrounding the location of the institute. The number of physicians accepted from each county will depend on the medical population of that county. Applications will be accepted in the order in which they are received, with the exception that, an attempt will be made to distribute the quota evenly throughout the individual county whenever possible. It is therefore necessary that those who are interested send in their applications early, before the quota of their county is exhausted.

No fee will be charged to those attending the institutes. The New York State Department of Health will reimburse traveling and maintenance expenses of those attending up to a maximum limit of \$20 per physician.

The institutes will consist of the following

1 Talks by outstanding authorities on pneumonia, i.e. Doctors Bullowa, Cecil or Cole, on various aspects of the diagnosis and treatment of the disease with special reference to serum therapy

2 Small group demonstrations on blood donors of the actual technic used in the administration of serum, the taking of blood cultures and the performance of sensitivity tests

3 Lecture and demonstration on the use of oxygen.

4 Informal discussions with the Speakers and other authoritative physicians regarding individual problems

5 Ward rounds by the Speakers on clinical material if cases are available at the time and place of the Institute

6 Sound moving-pictures illustrative of the technical aspects of serum treatment and nursing care in the home will also be shown.

The final schedule of the institutes and the place of meeting of each will be published in the next issue of the JOURNAL. A tentative schedule of the institutes with the counties served by each follows

Syracuse Institute, October 12

St Lawrence	Lewis	Onondaga	Broome
Herkimer	Jefferson	Cortland	Cayuga
Oneida	Oswego	Chenango	Madison

Rochester Institute, October 19

Wayne	Seneca	Schuyler	Tompkins
Tioga	Steuben	Ontario	Monroe
Livingston	Alleghany	Chemung	Yates

Buffalo Institute, October 25

Orleans	Genesee	Cattaraugus	Niagara
Chautauqua	Erie	Wyoming	

Albany Institute, November 9

Columbia	Albany	Warren
Schoharie	Saratoga	Hamilton
Schenectady	Washington	Franklin
Montgomery	Clinton	Otsego
Essex	Delaware	Fulton
Greene	Rensselaer	

New York City Institute, November 23

Suffolk	Nassau	Westchester
Rockland	Orange	Dutchess
Putnam	Ulster	Sullivan

Applications are to be sent to Dr Thomas P Farmer, Chairman of the Council Committee on Medical Education of the New York State Medical Society, 608 E Genesee St, Syracuse

Elmer's Mother—Doctor, I suppose you will be getting a good fee for attending little James Robey—the family are so rich?
Doctor—Why do you ask?

Elmer's Mother—Well, I hope when you send us your next bill you'll bear in mind that it was our Elmer that throwed the brick that hit James—*Pathfinder Magazine*

resultant cost, irreparable damage, and unpleasant publicity

The Committee, through its subcommittees, has heard informally the facts in a large number of cases involving negligence or malpractice on the part of reputable physicians. These include such cases as unavoidable deaths from delay in the giving of diphtheria antitoxin, late mastoidectomy, incurable cancer, etc. In these cases, the complainant is given opportunity to make a full and complete statement of his complaint and the physician is also given an opportunity to reply. If, in the opinion of the subcommittee, the facts indicate that the physician has acted properly, the matter is explained in great detail to the complainant from the medical viewpoint. So far as can be ascertained, none of these cases has subsequently appeared in the civil courts, thus saving many physicians igno-

many, waste of time and money in defending unfounded law suits based on alleged negligence and malpractice

The Committee has been of great benefit to both the public and the medical profession. It has eliminated from practice physicians guilty of reprehensible conduct. It has kept on the straight and narrow path physicians inclined to wander therefrom by reason of financial stress. It has raised the standards of professional practice. It has given protection to a large number of ethical practitioners improperly accused of misconduct. In short, in its eleven years of constant activity, at great sacrifice to the members' professional practice, without remuneration, the Committee has gained an enviable reputation for integrity, efficiency, and expedition. There are indications that similar activity will be imitated shortly in several other states

DISTRICT BRANCH MEETINGS

The Annual Meetings in 1937 will be held this fall on the following schedule

Sept	21	Sixth District Branch	at Owego
"	22	Seventh " "	" Geneva
"	23	Fifth " "	" Lowville
"	30	Third " "	" Kingston
Oct.	1-2	Fourth " "	" Glens Falls
"	5	First " "	" New York City
"	7	Eighth " "	" Olean
Nov	17	Second " "	" Garden City

INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION

The International Assembly of the Inter-State Postgraduate Medical Association of North America, under the presidency of Dr John F Erdmann of New York City, will be held in the beautiful new public auditorium of St Louis, Mo., October 18-22, with pre-assembly clinics on October 16 and post-assembly clinics October 23 in the hospitals of St. Louis

The aim of the program committee, with Dr George Crile as chairman, is to provide for the medical profession of North America an intensive postgraduate course covering the various branches of medical science. The program has been carefully arranged to meet the demands of the gen-

eral practitioner, as well as the specialist. Extreme care has been given in the selection of the contributors and the subjects of their contributions

The St. Louis Medical Society will be host to the Assembly and has arranged an excellent list of committees who will function throughout the Assembly

A most hearty invitation is extended to all members of the profession who are in good standing in their State or Provincial Societies to be present. A registration fee of \$500 will admit each member to all the scientific and clinical sessions

For further information, write Dr W B Peck, Managing-Director, Freeport, Ill

A bill is before the Colorado legislature providing for sterilization of all defendants who plead insanity and gain their point

when charged with murder or sex crimes. It looks good to this editor.—*Nebr State Med Jour*

CONNECTICUT CLINICAL CONGRESS

The annual Clinical Congress of The Connecticut State Medical Society, which was attended last year by 633 physicians from ten states, will be held this year in New Haven on Tuesday, Wednesday, and Thursday, September 21, 22, 23. The registration fee for the entire Congress will be \$2.00. The morning sessions, beginning at 9:30, will be held in the auditorium of the Sterling Law Buildings. The afternoon and evening sessions, beginning at 2:15 and 8:15 respectively, will be held in the buildings of the New Haven Hospital and the Yale School of Medicine. The evening meetings are section meetings which are open to all members of the Congress.

On Tuesday morning the President of the State Medical Society, Dr. Charles H. Turkington of Litchfield will preside. Dr. Francis C. Grant of Philadelphia will speak on "The Treatment of Cranial Trauma", Dr. J. E. Moore of Baltimore will speak on "The Treatment of Early Syphilis", Dr. Robert H. Aldrich of Boston will speak on "The Treatment of Burns with a Compound of Anilin Dyes" and Dr. Frederick C. Irving of Boston will speak on "The Place of Cesarean Section". The afternoon sessions will begin with bedside clinics by the speakers of the morning. Dr. Grant will present a case of Major Trigeminal Neuralgia, Dr. Moore a case of Uncomplicated Syphilitic Aortitis and Dr. Aldrich a case of Extensive Burns. Following this, questions pertinent to the papers read in the morning will be discussed at Panel Discussions. Dr. William J. German of New Haven will preside at the "Symposium on the Treatment of Cranial Trauma," Dr. Paul W. Vestal of New Haven at the "Symposium on the Treatment of Burns" and Dr. Stanley B. Weld of Hartford at the "Symposium on Cesarean Section". The new talking motion picture on Syphilis produced under the auspices of the United States Public Health Service and the American Medical Association will be shown in place of a symposium on Syphilis. In the evening the section on Dermatology and Syphilology, with Dr. E. Myles Standish of Hartford presiding, will hear Dr. George M. MacKee of New York speak on Precanceroses, and the Connecticut Public Health Association with Dr. Edward J. Godfrey of Waterbury presiding, will hear Dr. Robert P. Knapp of Manchester speak on "Progress of Industrial Medicine." The Connecticut Medical Examiners Association will also meet that evening with Dr. Henry N. Costello

of Hartford presiding. The program for that meeting has not yet been completed.

On Wednesday morning with Dr. Stanhope Bayne-Jones, Dean of the Yale School of Medicine, presiding, Dr. Isidor S. Ravdin of Philadelphia will speak on "Surgical Diseases of the Extrahepatic Bile Ducts", Dr. William B. Castle of Boston will speak on the "Treatment of Various Types of Anemias", Dr. Emil Novak of Baltimore will speak on the "Treatment of the Menopause" and Dr. Maurice Lenz of New York will speak on "Clinical Experience with the Use of Radium and X-Ray in the Treatment of Cancer". In the afternoon Dr. Ravdin will present a case of Lesions of the Extrahepatic Bile Ducts and Dr. Lenz will present Cases of Cancer of the Head and Neck. Dr. Daniel C. Patterson of Bridgeport will preside at the symposium on Surgical Diseases of the Extrahepatic Bile Ducts, Dr. Francis G. Blake of New Haven will preside at the symposium on Anemias, Dr. Emerson L. Stone of New Haven will preside at the symposium on Menopause and Dr. Douglas J. Roberts of Hartford will preside at the symposium on Radium and X-Ray. In the evening the meeting of the Section on Anesthesia will be a joint meeting with the American Society of Anesthetists with Dr. Leonard F. Del Vecchio of Bridgeport presiding. This meeting will hear Dr. Henry S. Ruth of Philadelphia speak on "Problems in Resuscitation," Dr. Louis S. Goodman of New Haven on "The Chemical Mediation of Nerve Stimuli," Dr. Paul M. Wood of New York on "Modern Anesthesia for Upper Abdominal Surgery" and Dr. Myer Saklad of Providence on "A Method for the Collection and Analysis of Anesthetic and Surgical Statistics". The section on Radiology with Dr. Kenneth K. Kinney of Wilimantic presiding will hear Dr. Bradley L. Coley of New York speak on "Diagnosis and Treatment of Bone Tumors" and Hezekiah Beardsley Pediatric Club will hear Dr. James D. Trask of New Haven speak on "Some Laboratory Studies in Poliomyelitis".

On Thursday morning Dr. Hugh B. Campbell of Norwich will preside. Dr. Oskar Diethelm of New York will speak on "Treatment of Psychoneurotic Disorders", Dr. Arthur Steindler of Iowa City will speak on "Fracture Deformities of the Upper Extremities—Wrist and Forearm," Dr. Claude S. Beck of Cleveland will speak on the "Treatment of Coronary Sclerosis and Angina Pectoris by Grafting a New Blood

Supply to the Heart" and Dr. Warfield T. Longcope of Baltimore on "Some Problems in Relation to Bright's Disease." In the afternoon Dr. Beck will show a motion picture showing the Treatment of Cardiac Compression, Dr. Longcope will present a case of Acute Nephritis and Dr. Steindler a case of Low Back Pain. At the symposium on Psychiatry—Anxiety Conditions, Dr. Eugen Kahn of New Haven will preside, Dr. Robert J. Cook of New Haven will preside at the symposium on Fracture Deformity, Dr. Louis H. Nahum of New Haven will preside at the symposium on Coronary Artery Disease and Dr. Milton C. Winternitz of New Haven will preside at the symposium on Bright's Disease. Following the symposium on Fracture Deformity, Dr. Robert M. Yergason of Hartford will demonstrate Emergency Fracture Splints of the Connecticut Fracture Committee, A.C.S. In the evening, the section on Orthopedic Surgery with Dr. Merrill K. Linsay of New Haven presiding will hear Dr. Arthur Steindler of Iowa City speak on the "State Program for Crippled

Children under the Social Security Act." The program for the meeting of the Section on Neurology and Psychiatry at which Dr. Charles T. LaMoure of Mansfield Depot will preside has not yet been completed.

The papers read before the Congress or complete abstracts of them will be published in subsequent issues of the *Journal of the Connecticut State Medical Society*.

On Tuesday and Wednesday afternoons members of the Congress will meet for a social hour at the New Haven Medical Association.

Section dinners will take place on the evening of the meeting of the respective sections.

The Women's Medical Society of Connecticut will hold a luncheon meeting in conjunction with the Congress. All women in medicine will be welcome.

Complete program and registration card can be obtained from the Chairman of the Committee on Publicity and Registration, Dr. Maurice J. Strauss, 41 Trumbull Street, New Haven Conn.

POLICE CHIEFS RAP LAY CORONERS

A recommendation that New York State's county coroners be supplanted by medical examiners—who must be licensed and experienced physicians—was unanimously adopted by the New York Association of Police Chiefs, on July 29.

The resolution asking the Legislature to abolish the office of coroner was proposed by Chief Inspector Albert B. Moore of the New York State Police at the closing session of a three day convention of police heads.

Inspector Moore pointed out that coroners in many counties are laymen, not qualified to conduct autopsies or properly

to advise police in the solution of crimes. There is danger, he declared, that such unskilled officials may handicap rather than assist the ends of justice.

The medical examiner system, he pointed out, already is in effect in New York City, Westchester and other counties.

The police chiefs also went on record in favor of a State law requiring immediate medical examination of persons arrested on suspicion of drunken driving. This measure, likewise introduced by Inspector Moore, demanded that authorities be enabled to "take proper steps to protect the people, instead of drunken drivers."

IN TIME OF PEACE PREPARE FOR WAR

The next annual inactive duty training period for medical reserve officers of the Army and the Navy will be held in Rochester, Minnesota, at the Mayo Clinic under the military supervision of the Surgeon of the Seventh Corps Area (Army) and the Surgeon of the Ninth Naval District (Navy) from October 3 to 16, inclusive.

The morning hours are devoted entirely to professional training given by the various departments or sections of the clinic at its several hospitals and institutions. The afternoon hours are devoted to lectures on professional subjects or military medicine.

The evening hours are given to lectures by distinguished visitors and the presentation of medico-military subjects.

The meeting is given for reserve officers of the Army and the Navy, and due military credits are given for attendance.

Enrollment is open to all Army and Navy reservists of the Medical Departments in good standing. Applications should be submitted to the Surgeon of the Seventh Corps Area, Omaha, Neb., or to the Surgeon of the Ninth Naval District, Great Lakes, Ill. Enrollment is limited to two hundred.

CONNECTICUT CLINICAL CONGRESS

The annual Clinical Congress of The Connecticut State Medical Society, which was attended last year by 633 physicians from ten states, will be held this year in New Haven on Tuesday, Wednesday, and Thursday, September 21, 22, 23. The registration fee for the entire Congress will be \$2.00. The morning sessions, beginning at 9:30, will be held in the auditorium of the Sterling Law Buildings. The afternoon and evening sessions, beginning at 2:15 and 8:15 respectively, will be held in the buildings of the New Haven Hospital and the Yale School of Medicine. The evening meetings are section meetings which are open to all members of the Congress.

On Tuesday morning the President of the State Medical Society, Dr. Charles H. Turkington of Litchfield will preside. Dr. Francis C. Grant of Philadelphia will speak on "The Treatment of Cranial Trauma", Dr. J. E. Moore of Baltimore will speak on "The Treatment of Early Syphilis", Dr. Robert H. Aldrich of Boston will speak on "The Treatment of Burns with a Compound of Anilin Dyes" and Dr. Frederick C. Irving of Boston will speak on "The Place of Cesarean Section". The afternoon sessions will begin with bedside clinics by the speakers of the morning. Dr. Grant will present a case of Major Trigeminal Neuralgia, Dr. Moore a case of Uncomplicated Syphilitic Aortitis and Dr. Aldrich a case of Extensive Burns. Following this, questions pertinent to the papers read in the morning will be discussed at Panel Discussions. Dr. William J. German of New Haven will preside at the "Symposium on the Treatment of Cranial Trauma," Dr. Paul W. Vestal of New Haven at the "Symposium on the Treatment of Burns" and Dr. Stanley B. Weld of Hartford at the "Symposium on Cesarean Section." The new talking motion picture on Syphilis produced under the auspices of the United States Public Health Service and the American Medical Association will be shown in place of a symposium on Syphilis. In the evening the section on Dermatology and Syphilology, with Dr. E. Myles Standish of Hartford presiding, will hear Dr. George M. MacKee of New York speak on Precanceroses, and the Connecticut Public Health Association with Dr. Edward J. Godfrey of Waterbury presiding, will hear Dr. Robert P. Knapp of Manchester speak on "Progress of Industrial Medicine." The Connecticut Medical Examiners Association will also meet that evening with Dr. Henry N. Costello

of Hartford presiding. The program for that meeting has not yet been completed.

On Wednesday morning with Dr. Stanhope Bayne-Jones, Dean of the Yale School of Medicine, presiding, Dr. Isidor S. Ravdin of Philadelphia will speak on "Surgical Diseases of the Extrahepatic Bile Ducts", Dr. William B. Castle of Boston will speak on the "Treatment of Various Types of Anemias", Dr. Emil Novak of Baltimore will speak on the "Treatment of the Menopause" and Dr. Maurice Lenz of New York will speak on "Clinical Experience with the Use of Radium and X-Ray in the Treatment of Cancer." This meeting will hear Dr. Henry S. Ruth of Philadelphia speak on "Problems in Resuscitation," Dr. Louis S. Goodman of New Haven on "The Chemical Mediation of Nerve Stimuli," Dr. Paul M. Wood of New York on "Modern Anesthesia for Upper Abdominal Surgery" and Dr. Myer Saklad of Providence on "A Method for the Collection and Analysis of Anesthetic and Surgical Statistics." The section on Radiology with Dr. Kenneth K. Kinney of Willimantic presiding will hear Dr. Bradley L. Coley of New York speak on "Diagnosis and Treatment of Bone Tumors" and Hezekiah Beardsley Pediatric Club will hear Dr. James D. Trask of New Haven speak on "Some Laboratory Studies in Poliomyelitis."

On Thursday morning Dr. Hugh B. Campbell of Norwich will preside. Dr. Oscar Diethelm of New York will speak on "Treatment of Psychoneurotic Disorders", Dr. Arthur Steindler of Iowa City will speak on "Fracture Deformities of the Upper Extremities—Wrist and Forearm," Dr. Claude S. Beck of Cleveland will speak on the "Treatment of Coronary Sclerosis and Angina Pectoris by Grafting a New Blood

An Outbreak of Typhoid Fever in Schenectady

On Memorial Day a group of thirty-one or more persons, members of a local organization in Schenectady, met to partake of refreshments at the close of Memorial Day exercises. Most of the various articles of food which comprised the luncheon had been prepared by members of the organization at their homes and were served from the original containers, serving spoons being placed in the dishes.

Of the thirty-one persons known to have

been present nine have developed clinical typhoid fever and one of these has died. The date of onset of illness of the first case was reported as June 5.

Epidemiological data thus far obtained point either to potato or macaroni salad as the vehicle of infection. Further investigation is being carried on, especially with a view to discovering a possible typhoid carrier as the probable source of infection.

—*Health News*, July 19, 1937

An Outbreak of Smallpox

An outbreak of smallpox comprising eleven cases, ten in Niagara Falls and one in the Town of Niagara, Niagara county, was discovered on August 6. On that date the health officer was requested by a local physician to examine a patient from the town of Niagara, suspected of having smallpox. The health officer found the case to be smallpox. Investigation disclosed that in addition to the town case there had been ten cases in Niagara Falls, with onsets of illness between June 21 and August 3, none of whom apparently had called a physician. The cases were limited to four related households in an isolated section near the city limits.

The outbreak is believed to have originated from a case in a family who ar-

rived in Niagara Falls from Utah on June 7, following exposure to alleged chickenpox just previous to their departure from that State.

Local health officials concerned and members of the staff of the State Department of Health have cooperated in controlling the outbreak. Twenty-two known immediate contacts have been vaccinated and are under strict quarantine. Upwards of 200 other persons living in the immediate neighborhood also have been vaccinated and a house to house vaccination project in this territory is nearly completed. The outbreak is believed to be sufficiently under control so that visitors to Niagara Falls need feel no special concern.

—*Health News*, August 16, 1937

PUFF OR VANITY SHEETS

Publications having high-sounding names, often not regularly issued and frequently without any subscription circularization, are classified as the "vanity" type of publication by the trade. A number of such publications exist in New York City.

Recently physicians have been solicited by one of them.

They are generally published when there is a sufficient amount of the "puff" and "vanity" type of business secured. The circularization is mainly confined to the number of copies that the solicited individual is gullible enough to purchase. They are operated about as follows:

Generally the head of the publishing concern scans the newspapers daily and notes the names of visitors or others who have been quoted in the press. Persons from out

of town are particularly desirable "victims." The names and whatever information is available is turned over to a staff of writers who write stories of varying lengths. These stories are turned over to solicitors who get in touch with the person concerned and endeavor to read the article, to gain approval of it, and to sell as many copies as possible of the issue containing the article to the persons thus approached. These writers and solicitors work on a commission basis, being paid only when their work brings in a sale of copies.

Caveat emptor—Let the purchaser beware!

Let the seller beware—has not yet come to pass.

Public Health News

Cases of Cowpox Originating from Vaccination

THIS JOURNAL of August 15, 1936, published a report by Dr Stanley W Sayer and Dr Franklyn B Amos, of the district staff of the New York State Department of Health, of an instance of transmission of cowpox from a recently vaccinated person to several cows and from the cows to other persons. The authors, at that time, said that they had been able to find no previous similar report in medical literature. Dr Amos has now reported another series of cases which recently developed in another section of the state under almost identical circumstances.

Another member of the department staff, stationed at Albany, was told by a friend that members of her family were reported to be suffering from cowpox. The family lived on a farm in the district which Dr Amos was working and, his interest in the subject being recalled, he was advised of the report and made an immediate investigation. The facts, as reported by Dr Amos, are summarized.

R P, age eighteen, was vaccinated on June 7, the vaccination giving a primary reaction and running an uncomplicated course. R P assisted in the care of a herd of about twenty cows. About June 18 it was observed that "the cows" (number not stated) were infected with cowpox. About June 28 several lesions appeared on the forearm of a young brother, T P, who also had assisted in the care of the cows. A physician who examined

the lesions on July 2, stated that they had the appearance of "typical vaccination pustules." This boy also developed lesions on his face and, from July 2 to 5, was acutely ill, his temperature reaching 103°. When seen later by Dr Amos the lesions had disappeared and he had "twelve typical vaccination scars" on his forearm and two on his face. About July 5, M P, a thirteen year old boy who also had been in contact with the cattle, developed a "vaccination lesion" on his hand. This apparently ran an uncompleted course and left a typical scar.

The only other member of the family who handled the cows was F P, the father. He had been vaccinated four times, the last time about twenty-five years before. He was not infected. Other members of the family, who did not come in contact with the cattle and were uninfected were the mother, vaccinated about forty years before, an adult son, and two younger children, none of whom had been vaccinated.

Dr Amos, in his report, mentioned "an economic side" of the matter. One of the cows, which apparently recovered ultimately, was at one time in such a condition that it was believed she would have to be destroyed. At this time Mr F P threatened to sue the physician who had performed the original vaccination for damages covering the value of the cow—

State Cancer Institute Makes Important Change in Policy Physicians Required to Apply for Admission of New Patients

Owing to the great demands on the medical, nursing, clerical and bed facilities of the State Institute for the Study of Malignant Disease, it will be necessary from now on for physicians to make application for the admission of new patients setting forth the type of lesion, extent of the disease, physical condition of the patient, factors of any previous treatment given, and operative findings, if any. (In cases where biopsy has been done, the slide should be sent with the patient provided the tissue has not been previously submitted to the Institute laboratory.) On receipt of this information, so far as possible, an early

appointment will be made for the reception and thorough treatment of the patient if in the judgment of the Institute it is warranted.

With the cooperation of physicians under this policy, it is hoped that patients may be better served and that those who offer the greatest possibility of relief by irradiation may be cared for more efficiently. So far as possible, the general diagnosis of gastrointestinal diseases should be made at the general hospitals as the Institute facilities and supplies are very limited.

An Outbreak of Typhoid Fever in Schenectady

On Memorial Day a group of thirty-one or more persons, members of a local organization in Schenectady, met to partake of refreshments at the close of Memorial Day exercises. Most of the various articles of food which comprised the luncheon had been prepared by members of the organization at their homes and were served from the original containers, serving spoons being placed in the dishes.

Of the thirty-one persons known to have

been present nine have developed clinical typhoid fever and one of these has died. The date of onset of illness of the first case was reported as June 5.

Epidemiological data thus far obtained point either to potato or macaroni salad as the vehicle of infection. Further investigation is being carried on, especially with a view to discovering a possible typhoid carrier as the probable source of infection.

—*Health News*, July 19, 1937

An Outbreak of Smallpox

An outbreak of smallpox comprising eleven cases, ten in Niagara Falls and one in the Town of Niagara, Niagara county, was discovered on August 6. On that date the health officer was requested by a local physician to examine a patient from the town of Niagara, suspected of having smallpox. The health officer found the case to be smallpox. Investigation disclosed that in addition to the town case there had been ten cases in Niagara Falls, with onsets of illness between June 21 and August 3, none of whom apparently had called a physician. The cases were limited to four related households in an isolated section near the city limits.

The outbreak is believed to have originated from a case in a family who ar-

rived in Niagara Falls from Utah on June 7, following exposure to alleged chickenpox just previous to their departure from that State.

Local health officials concerned and members of the staff of the State Department of Health have cooperated in controlling the outbreak. Twenty-two known immediate contacts have been vaccinated and are under strict quarantine. Upwards of 200 other persons living in the immediate neighborhood also have been vaccinated and a house to house vaccination project in this territory is nearly completed. The outbreak is believed to be sufficiently under control so that visitors to Niagara Falls need feel no special concern.

—*Health News*, August 16, 1937

PUFF OR VANITY SHEETS

Publications having high-sounding names, often not regularly issued and frequently without any subscription circularization, are classified as the "vanity" type of publication by the trade. A number of such publications exist in New York City.

Recently physicians have been solicited by one of them.

They are generally published when there is a sufficient amount of the "puff" and "vanity" type of business secured. The circularization is mainly confined to the number of copies that the solicited individual is gullible enough to purchase. They are operated about as follows:

Generally the head of the publishing concern scans the newspapers daily and notes the names of visitors or others who have been quoted in the press. Persons from out

of town are particularly desirable "victims." The names and whatever information is available is turned over to a staff of writers who write stories of varying lengths. These stories are turned over to solicitors who get in touch with the person concerned and endeavor to read the article, to gain approval of it, and to sell as many copies as possible of the issue containing the article to the persons thus approached. These writers and solicitors work on a commission basis, being paid only when their work brings in a sale of copies.

Medical News

Broome County

A PROPOSAL THAT the Broome County Medical society establish a system whereby relief clients may be examined and treated by their own physicians at public expense is to be presented to the Broome County Planning commission as a possible means of cutting down relief costs in the county, according to press reports

The suggestion comes from Clement V Conole, district superintendent of the division of placement and unemployment insurance of the State Department of Labor and chairman of the planning commission's committee on local government

Under the proposed plan, as outlined by Mr Conole, "the county medical society would set up a system for examining and prescribing care and treatment for relief cases. The latter would report to their own physicians who would be paid from relief funds on a stipulated basis, corresponding somewhat to the present system of compensation claims"

The committee head pointed to a possibility of Federal Department of Health assistance in such a program since it had recently received a large appropriation

Mr Conole is confident that the suggestion would be more popular with medical men than the free dispensary or clinic system of caring for needy persons because each person would continue under the care of his own family physician

Possible saving in relief expense is seen in the fact that many persons fail to obtain employment because of ill health or physical defects that might be overcome under supervised diagnosis and treatment.

Chautauqua County

THE SIXTH ANNUAL INTERSTATE medical meeting, sponsored by the Chautauqua County Medical Society was held on July 28 at Chautauqua. Scientific sessions were held in the morning and lectures to lay people in the afternoon. On the program were Dr Walter Alvarez of the Mayo Clinic Foundation, Dr Russell Cecil, Professor of Medicine of Cornell University Medical School, and Dr Winfield Scott, Professor of Urology of University of Rochester. In the afternoon, the same speakers addressed a lay audience in the amphitheater. Dr Cecil spoke on "Plight of the Arthritic", Dr Walter Alvarez on

"Nervous Indigestion". A program of entertainment was arranged, composed of golf tournament with prizes, boat ride on Chautauqua Lake, and in the evening, a concert by the Chautauqua Symphony Orchestra with Beryl Rubinstein piano soloist and Albert Stoessel conducting

Erie County

CREATION OF A MEDICAL DIVISION in the County Welfare department for the medical and dental supervision of all welfare activities of the department was voted July 16 by the Finance committee of the Board of Supervisors and approved by the Board, July 20

The action was taken on recommendation of County Welfare Commissioner James C Lees, after an eight months' study of the need for a central medical setup in his department

Dr William Handel, a member of the committee on Economics and Public Relations of the County Medical Society, has been designated as medical supervisor in charge of the division. Commissioner Lees explained Dr Handel's activities will be confined entirely to supervision. The Erie County Medical and Dental societies will cooperate with him

The new division will include four nurses and sixteen clerks - Dr C M Roberts is in charge of dental supervision

The division will have charge of medical treatments for home relief and blind relief clients, persons receiving old-age pensions, child wards in homes and institutions, mental cases, and for persons receiving hospitalization. The set-up will be ready for release September 1

ATTEMPTS TO FORMULATE a plan for extending existing medical service to indigent patients and at the same time to provide remuneration for physicians in these cases were discussed on June 30 by representatives of various agencies concerned at a meeting in Hotel Statler in Buffalo

The meeting, sponsored by the Medical Society of the County of Erie, was attended by members of the Council of Social Agencies and the State Department of Social Welfare.

Two plans were proposed, not dissimilar in many aspects, by Dr Walter S Goodale, superintendent of the City hospital, and by the Medical society

Dr Goodale's plan provides that a panel of doctors be set up, composed of all who wished to cooperate in the plan. All hospitals in the county would be at liberty to extend bed care to charity cases.

The administration of the system could be accomplished through the City hospital, with doctors and hospitals sharing in a set stipend paid from public funds.

The Medical society advocated a panel of doctors, co-ordinated by a committee from the society, who would care for indigent patients in their homes at a set fee established by the committee in conjunction with the Council of Social Agencies.

William J O'Brian, director of the State Department of Social Welfare, pointed out that if the city of Buffalo had been operating under the latter plan, a reimbursement of 40 per cent of the funds expended for care of indigents could have been claimed from state ERB funds.

Greene County

A REGULAR MEETING of the Medical Society of Greene County was held at the Ledge End Inn, Twilight Park, Haines Falls, Tuesday, July 13, when Dr E C Boaf gave an address on diseases of the heart and coronary arteries.

Kings County

BROOKLYN'S MEDICAL, HEALTH AND WELFARE agencies and the public in general in the Williamsburg-Greenpoint section rejoiced as the Department of Health dedicated the new \$238,869 health center at 150 Maujer Street, facing the Williamsburg Federal housing project, on July 28.

A luncheon in the new building marked the dedication ceremonies with Mayor LaGuardia, Borough President Ingersoll, and Health Commissioner John L Rice as the principal speakers. Presiding was Dr James Steele, chairman of the district's medical advisory committee.

This was the fourth of eight City-owned, City-built district health center buildings to be opened in the five boroughs this year, and the first in Brooklyn. Its financing was aided by the Federal Emergency Administration of Public Works.

"A neighborhood house of health," as Commissioner Rice calls it, it will serve a population area of 250,000 residents, bringing the facilities of the Health Department into the district with emphasis on preventive medicine and health education.

Quartered in the building are dental and hygiene clinics, maternity and infant welfare clinics and tuberculosis, x-ray, venereal disease sections and eye clinics.

It also houses space for visiting nurses and for voluntary health and welfare agencies working in the district, an auditorium with stage, an exhibit room and a conference room for doctors.

Among the 200 guests at the luncheon were Arthur S Tuttle, State director, Federal Emergency Administration of Public Works, Dr Thomas A McGoldrick, president, and Dr Alec N Thomson, director of medical activities, of the Medical Society of Kings, Bailey B Burritt, chairman of the executive committee, Committee on Neighborhood Health Development, and Douglas P Falconer, general secretary, Brooklyn Bureau of Charities.

Livingston County

DR. FREDERICK JOHN BOWEN, seventy-two, a well-known resident and physician of Mount Morris for forty-seven years, died at his home in July of lympho-sarcoma, after an illness of nine months.

New York County

A SYPHILIS CENSUS, similar to that projected for Chicago, where all citizens will be asked to take blood tests, has already been taken several times in New York City and has shown that about five per cent of the local population is infected, Dr John L Rice, Commissioner of Health, says. The censuses showed that of those infected, only one person in eight or nine is under medical care.

It was also learned that the Health Department's distribution to private physicians of free doses of bismuth and salvarsan, used for treating the disease, doubled during April, May, and June over the amount distributed free in the first three months of this year. The later figure was about 50,000 doses, given out to 688 doctors and more than forty voluntary hospitals.

Dr Rice said the city's Health Department completed syphilis censuses in 1928 and 1935 and also tested over many years such groups in the city as pregnant women, food handlers and certain racial groups. The State Department has also made censuses, he said.

"The Department of Health," he declared, "as a routine, performed over 300,000 blood tests last year and the number of applicants for the blood tests is constantly increasing in response to steady educational effort, and extended modern facilities in the hands of private physicians and in clinics."

The clinics are distributing lists of qualified private physicians willing to treat syph-

ilitic patients for as little as \$2 or \$3 a visit. The lists were furnished by the county medical societies.

DR. JAMES RAMSAY HUNT, professor of neurology at Columbia University and director of the neuro-psychiatric division of the New York Neurological Institute, died on July 22 at his summer home at Katonah, Mount Holly Farm. He was sixty-three.

Dr. Hunt was president of the New York Neurological Society in 1909, president of the American Neurological Association in 1920, president of the American Psycho-Pathological Association in 1932 and of the Association for Research in Nervous and Mental Disease in 1934. He was also a founder member of the American Society for Clinical Investigation.

Dr. Hunt contributed many authoritative articles to medical journals and was the author of numerous works on medicine which have become standard, including "The Pallidal System," "The Static and Kinetic Systems of Motility," and many others.

NURSES AND EXAMINERS of the Lower Harlem Chest Clinic, at 111 West 116 St., are going out among the populace of Harlem to induce possible cases to have diagnostic x-ray pictures taken. They have already made more than 50,000 visits, according to a WPA bulletin. The clinic is staffed largely by WPA personnel. Harlem is the sore spot in the city's tuberculosis problem. But, it has been discovered, a large proportion of the group which most needs a clinic's services is held back by fear. Many of the Negroes of Lower Harlem have been told that the clinic is a dangerous place to visit. Some of them confuse the term "x-ray" with a wildly improbable "death ray." If they are left to themselves, the clinic is the last place from which they seek assistance.

To counteract this feeling, members of the clinic's visiting staff go to the homes of Harlem residents whose names have been furnished by the Emergency Relief Bureau and attempt to explain the benefits of the service. The visitors take with them snapshots of the clinic as well as finished x-ray pictures. These show prospective patients far better than words the merits of the work being done. To many the x-ray pictures prove so intriguing that they decide to come in and have some taken of themselves.

The clinic has recently placed in operation a celluloid x-ray machine, which makes it possible to give detailed diagnoses of patients who formerly had to be referred

to other clinics for such work. Previously, the clinic had used only the new paper films. These are still being used for general examination work to determine the presence of the disease, but celluloid films are necessary for discovering the finer details, the differences and significant shadows, which furnish the physician a true picture of the individual case.

Oneida County

A FEATURE OF THE DEDICATION of the new \$162,000 annex to the Oneida County Hospital in July was an address by Dr. William Hale, president of the County Medical Society. He declared that the annex presented a possibility for the development of a cancer clinic, "something badly needed in this county."

"It would be a wonderful thing for Oneida County to have a county clinic, a clinic for treatment of all cancer cases in the county and for study and early diagnoses of early cancer," Dr. Hale said.

Dr. Hale's suggestion for a clinic was endorsed by Floyd W. Fenner, county commissioner of public welfare, who followed him as a speaker. Mr. Fenner cited the need and importance of such a clinic and the tremendous benefits it would bring to sufferers and the county itself.

Dr. Hale, after suggesting the cancer clinic, continued in part:

Speaking for the Oneida County Medical Society, I congratulate the people of this county on having a Board of Supervisors who had the necessary vision to construct this new addition. The Medical Society appreciates thoroughly the need of this addition.

But the physicians in this county view with alarm and a great deal of regret the facts that the events of recent years may have so diminished the pride of some people who instead of seeking admittance at regular hospitals through regular channels are willing to come to the "poor house" and are pulling wires to have their families admitted here for medicine and surgery and are placing themselves in the position of indigents.

Surely our pride has had a great fall. Those who are able to pay their way should be instructed to go elsewhere for treatment so they will not occupy a bed that is already needed for someone less fortunate.

But it is not alone the community that is to be blamed. Some physicians have developed a habit of sending their patients here for everything and usually as an emergency, thus depriving the superintendent of his option of accepting the case and also upsetting the routine methods which the commissioners have tried so hard to establish.

In the days of our fathers it was not smart to accept charity and I wish to impress upon every resident of this county, upon every

doctor in the county and upon every superior elected in the county and whose influence in this matter is frequently sought and upon you all that the patient in this hospital is accepting charity in every sense of the word when he enters for treatment and our sympathy goes to him when he is forced to ask for this charity. And when this charity is required we are thankful that we have this well-organized institution still more efficient by the completion of this splendid addition.

Onondaga County

DENOUNCING CERTAIN PHYSICIANS of the Syracuse area whom he termed as "unscrupulous" because of their part in illegally supplying drugs to addicts, Major Garland Williams, district supervisor of the United States bureau of narcotics, came to Syracuse on July 7 to inspect the local bureau and to probe details of the Dr Norman W Foster arrest for dispensing drug prescriptions. He said "Recent cases in this district have pointed out an alarming tendency of certain unscrupulous physicians to supply narcotics to common addicts. The medical profession as a whole has always co-operated with the narcotic bureau and we implore the profession to continue to aid us in our work. Institutions are now provided for addicts, and in many cases prescriptions for dope are not needed as much as careful treatment."

R. MARCUS DICK, of Cranston, R. I. Syracuse University graduate with the class of 1937 and honor student in the campus R. O T C regiment, was named executive secretary of the Onondaga Medical Society in July by Dr Joseph Wiseman, president. Creation of the new position was announced by a committee headed by Dr Gordon D Hoople of the society. An office will be established as clearing house for all medical, legislative and social problems affecting the profession. Dick is a graduate of the College of Business Administration where he majored in general business subjects.

Ontario County

DR. GEORGE B ADAMS, director of the Cayuga County Laboratory, and acting coroner of Cayuga County since the illness and recent death of Dr A. F Hodgman, addressed the Ontario County Medical Society at a meeting on July 13 at Clifton Springs Sanitarium. Doctor Adams' topic was "Some of the Ways that Laboratory Medicine May be Advantageously Used in Clinical Medicine."

Orange County

DR JOHN TAYLOR HOWELL, long prominent in Orange county medical circles, died in Newburgh on July 10 following a two months' illness. Just five months before his death he had completed fifty years of practice in Newburgh. He was one of the organizers of St Luke's Hospital and the first chief of its medical staff. He had continued a member of the medical and surgical staff of the hospital from its beginning until his death.

Queens County

THE MEDICAL SOCIETY of the County of Queens will hold a joint meeting with the Queensboro Tuberculosis and Health Association, Sept 22, at the Medical Society's building.

A golf tournament and putting contest will precede the dinner which will be served at the Queens Valley Golf Club. The meeting will be held after the dinner.

Dr Jay Arthur Myers, president of the National Tuberculosis Association and professor of medicine and public health at the University of Minnesota, will give an illustrated lecture on "Tuberculosis in Childhood."

THE MEDICAL SOCIETY of the County of Queens, Inc., under the auspices of its Public Health Committee, has awarded a cup to the writer of the prize winning essay on the child health exhibit which the society held at its building last May.

The cup was awarded by Dr Henry A Reisman, chairman of the Public Health Committee, to Miss Florence Kuhle of Bayside at the American Legion Hall in Bayside.

St Lawrence County

THE ST LAWRENCE COUNTY Medical Society met at the Massena Country Club on July 22 as guests of the Massena doctors. Fifty-four members and their wives were present. Dinner was served and the afternoon was spent in golf and bridge.

Wayne County

THE AUGUST MEETING OF THE Wayne County Medical Society was held at Sodus Bay Heights Country Club on August 3. A sports program, including golf, swimming, cards, and boating was enjoyed and dinner was served. The scientific program featured reports and discussion of lead poisoning and melanotic sarcoma cases by Society members.

Hospital News

The Volunteer Workers

MANY NEW FACES APPEARED in various hospitals which use volunteer workers when the women's colleges closed for the summer. An influx of girls from Wellesley, Smith, Bryn Mawr, Skidmore, Barnard and Hunter replaced other volunteer workers who live near the hospitals and give part of their time during the winter. An informing article on this topic appears in the *New York Times* by Miss Charlotte Hughes, who speaks especially of the volunteer system as it works at the New York Hospital.

She tells us that the number of volunteer worker in hospitals in New York and other cities is increasing, and the value of their services to doctors and nurses is being appreciated more and more, according to Miss Beatrice Meyer, secretary of the volunteer department at New York Hospital. Miss Meyer is now making a survey of volunteer work in hospitals throughout the United States.

The volunteers go quietly about the buildings of New York Hospital clad in blue uniforms that distinguish them from the regular nurses and paid hospital assistants. Their work is not spectacular. They do the necessary odd jobs that doctors and nurses relegate to them. These jobs are not the sort that would amuse a dilettante. They require hard work, perseverance and something more than a vague desire to play nurse in a real hospital.

Doctors and nurses at the New York Hospital are asking increasingly for help from the volunteer corps, and are expressing gratitude for the aid they receive, Miss Meyer says.

Eighty-eight volunteers put in 7,000 hours of work at the New York Hospital during April, a figure that breaks all records for the five-year-old service. Eighteen of these women worked full time, forty-three hours a week. Thus staff doctors, internes and nurses were relieved of much tedious routine and were enabled to put in more time on research.

Volunteers always work under the direction of a hospital staff member. They supplement work done by paid personnel, and do not invade fields covered by paid workers. Requests for volunteers are made only when appropriations for paid workers have been exhausted.

Volunteers with college degrees and

courses in chemistry or bacteriology among their credits are given coveted work as laboratory assistants. These openings are rare. They enable a college girl to continue her laboratory studies and to put behind her some practical experience valuable in job hunting. One girl helped a doctor by conducting skin tests for his research on hay-fever allergy. Another helped in research conducted through feeding rats a copper-free diet. A third had charge of some chimpanzees, which she fed a special diet in connection with cardiac research in the pediatric department. She had to keep careful records of the pulse and respiration of the animals.

A girl who is efficient at shorthand has been taking medical dictation while doctors operate on dogs in the department of experimental surgery. She has been doing this on a volunteer basis for almost a year, giving her entire time to it and making extensive histories of each experiment.

Knowledge of the calorie content of food comes in handy for a certain volunteer who works in the hospital's nutrition department. This girl is specializing in home economics at Hunter College, thus dovetailing her school and hospital work. She takes orders from patients for their meals, checks the calorie content and aids the dietitian in charting the calorie consumption of each patient.

An experiment conducted in the hospital's arthritis department also utilizes a volunteer aide, who makes careful calculations of the rate of flow of red blood cells. This job requires real technical knowledge. It is no work for a dabbler.

Sometimes a doctor at the hospital wants to undertake some research and experimentation for which there is no special appropriation of funds. He can call on the volunteer corps for a helper. If it is in an original field, he wants a girl who can wade through a great amount of literature on the subject and prepare a bibliography for him. One girl had to weed out sources on blood transfusions and their reactions on children.

It is not every volunteer who is equipped to render such technical service to the hospital. Some of those with less training take on work as volunteer clinic aides, answering the telephone, filing card slips, giving reappointments, sending for records.

Volunteers working under nurses in

charge of pavilions fix flowers for the patients, write their letters and do errands for them. They enter records of temperature, weight, respiration and pulse, and help with the linen. Sometimes they feed the patients.

The unpaid workers are coached beforehand in the attitude they are to take toward a patient. They are to consider his feelings and anxieties, and to be considerate, interested and cheerful. The volunteers are told to have no opinions as to the diagnosis of the patient's symptoms or the efficacy of

treatments or medicines prescribed. They never give advice that might be interpreted by the patient as coming from one in authority.

Volunteer work in hospitals grew to important proportions during the depression, when hospital incomes fell off and when trained girls found hospital and laboratory jobs scarce. The work has grown steadily since then and has not fallen off, though money for hospital use has become more available in recent years.

Perilous Visitors

VISITING DAYS IN THE HOSPITAL cannot be said to be an unmixed blessing. The coming and going of a great number of people with inevitable patient contacts represents, especially in the maternity and pediatric departments, a definite health hazard, believes *The Modern Hospital*. Indeed, in some hospitals conducted for the care of children, the institution known as visiting day has been relegated to the past. In such hospitals elaborate and costly physical arrangements are sometimes installed for the prevention of the transmission of infection from the visitor to the child patient.

When such arrangements are not made, even though parents are permitted to see their children, this privilege is granted only at weekly or even at more infrequent times. Indeed, the benefit and pleasure derived from permitting visitors to the pediatric department are largely one-sided, for the child, after a few days in a hospital bed, quickly adjusts himself to institutional routine and cries only when parents arrive and leave and rarely in their absence.

The maternity department represents another example of a hospital division from which, if possible, visitors might well be excluded. To be sure the prideful husband develops a mighty chest expansion and experiences undoubted pleasure in visiting the

mother and the new member of his family. Doting grandparents, aunts and uncles are drawn irresistibly to the maternity department on visiting days. To prevent the handling of infants by fond relatives, the soiling of a patient's room or bed by careless and unclean visitors represents a real problem in hospital public health.

The sight of a crowded maternity corridor and a nurse with baby in arms endeavoring literally to fight her way through in order that she may deliver the infant to its mother is not uncommon in our hospitals. Little wonder that impetigo and other infections occur in the presence of this daily or tri-weekly deluge of well meaning but potentially infective visitors. Reasoning, explaining, cautioning or even ordering exerts but little quieting effect upon their curiosity and misplaced affection.

To clear the department of outsiders at nursing time might be helpful, to prevent the visiting of children there is certainly indicated and if necessary visiting hours should be temporarily abandoned in the presence of threatening infection. Patients are much more easily handled than are their relatives who, because of ignorance, permit selfishness to prevail where thoughtfulness for the welfare of the mother and child should be foud.

Newsy Notes

THE MANY NEW BUILDING PROJECTS here lend interest to a special hospital issue of the *Architects' Journal* (London, June 24, 1 shilling) which illustrates some of the best recent hospital construction in Great Britain. The work shown in this issue, says the *British Medical Journal*, "is not only a delight to the eye, but furnishes an example of perfect adaptation to modern

ideas in institutional treatment of the sick." It adds "The largest problem in hospital construction is vertical versus horizontal planning. The vertical hospital has great advantages to offer in convenience for the staff, but it is also very costly and, unlike the horizontal hospital, not easily altered when it becomes out of date, as it may easily do in twenty years."

LOUIS T. STRAUSS, a director of the Jewish Hospital of Brooklyn and proprietor of a meat market at 125 Smith St., has announced his resignation from his hospital post in a letter to Morris Berlin, vice-president of the Hospital Employes' Union, which has been conducting a strike at the institution since last March. In the letter, Strauss recounted his sympathy with the strikers and expressed his disagreement with the policy of the hospital directorate. Made public at the same time was a letter from Nathan Jonas, president of the hospital, accepting Strauss' resignation and thanking him for his many years of service. Mr. Jonas later stated that Strauss' market had been picketed and that the hospital board had been informed of the distress which the action was causing Strauss. Mr. Jonas indicated this was the real reason for the resignation.

A "NEW WAY" WITH CHRONIC PATIENTS

ON WELFARE ISLAND there is a small hospital unit called the Research Division of Chronic Disease, which will serve as a model for the new Welfare Hospital when that is finished.

The atmosphere is optimistic and bustling—almost gay—the women patients wear bright ribbons in their hair, the men do embroidery, says an article in the *New York Journal*. The beds are green, not white, there are maps on the walls and pictures of movie stars and baseball players, and samples of the patients' handiwork.

All the patients look pleased and interested and gossipy—yet when they came into the unit they were typical samples of the forlorn half-hopeless specimens that drift into the city hospitals labeled "chronic."

"It's a new way of treating chronic patients," explains Dr. C. George Scherf, medical superintendent of Metropolitan Hospital. Usually the chronic patients are the 'orphans' of the hospitals; they find themselves in them. They're not dramatic like acute cases that need immediate care and show immediate results.

"So they get shunted from pillar to post, given barely custodial care, when in many cases much could be done for them."

The chronic diseases whose possible causes are being studied in the Research Division are cirrhosis of the liver, rheumatoid arthri-

tis, hypertension, Bright's disease, and asthma, as well as others.

"This," said Dr. David Seegal, director of the unit, "is a sort of trial horse. Our hope is that if this model works, the idea will permeate to hospitals in other cities."

"The staff here has an optimistic point of view. We've tried to eliminate the usual sterilized veneer of the usual hospital. We've tried to make the patients feel that the golden rule is at work here, we've given them the privacy so often lacking in hospital wards—and most important, we've given them some place to go besides bed."

TUBERCULOSIS HOSPITALS FAR BEHIND THE NEED

DR. S. S. GOLDWATER, Commissioner of Hospitals, announces the results of a fresh survey of tuberculosis hospital service in the City of New York. The total normal capacity of tuberculosis hospitals and wards in twenty-one public and private institutions is 4578. The number of patients cared for on July 2 was 4980. Patients, therefore, exceeded the normal bed capacity by 402. In addition, the Tuberculosis Hospital Admission Bureau of the Department of Hospitals, which cooperates with tuberculosis clinics and welfare agencies had knowledge of 392 waiting cases for hospital care.

To relieve existing overcrowding and to accommodate waiting applicants, the Department of Hospitals has in hand four building projects in Manhattan, Queens, Richmond and the Bronx, which, when completed, will make available approximately a thousand additional beds. Of this number, 250 are in the new Children's Building at Sea View, which is rapidly approaching completion, and 150 in the new tuberculosis wards at Bellevue, which will be turned over to the Department of Hospitals for equipment in the Fall. The Triboro Hospital for Tuberculosis, to be erected on a plot adjoining the present Queens General Hospital, will accommodate 500 patients; this project is still in the planning stage, as is the project for a group of tuberculosis wards in the Bronx.

The New York Tuberculosis and Health Association has again appealed to the City to provide 2500 tuberculosis beds over and above those available.

Improvements

FIVE NEW HOMES for physicians have been built in the Middletown State Hospital grounds. The hospital chapel will be completely remodeled. Each house has eight rooms, garage, and study. The kitchens have complete electrical equipment.

A NEW \$100,000 CHILDREN'S hospital with fifty rooms, is to be built in Buffalo. The new hospital already has the approval and commendation of national pediatricists. Dr. Walter J. Craig, director of orthopedics at Albany, has praised the plans and said it would be one of the best of its kind in the United States. It will be modeled after one affiliated with Johns Hopkins Medical School at Baltimore.

UNDETERRED BY A THREATENED lawsuit to test the will of the late Nettie M. Roe providing for the proposed John Van Brunt Roe Hospital, Joseph T. Losee, attorney for the trustee of the Roe estate, has announced that the Patchogue Citizens Bank & Trust Company, estate trustee, will pro-

ceed with the acquisition of the hospital site and the construction of the building. The threat of an action against the will was first made six months ago by the Patchogue law firm of Shaw, Greene & Kernis, who announced they had been retained by unnamed second cousins of the late Miss Roe. Efforts to expedite this proposed lawsuit failed when Surrogate Robert S. Pelle-treau ruled that he had no jurisdiction in the matter.

BIGGS MEMORIAL HOSPITAL at Ithaca will spend over \$45,000 on new roadways.

THE HOLY FAMILY HOSPITAL in Brooklyn will install a new elevator at a cost of \$12,000.

THE MEDINA MEMORIAL HOSPITAL will expend \$2500 to \$3500 in beautifying and landscaping the grounds. The funds will be raised by the Junior Chamber of Commerce.

At the Helm

DR. J. LEWIS DONHAUSER AND DR. L. WHITTINGTON GORHAM have been appointed, respectively, surgeon-in-chief and physician-in-chief to Albany Hospital. Dr. Arthur J. Wallingford was named gynecologist. The appointments were brought about by resignation of Dean Thomas Ordway as executive head of Albany Medical College's department of medicine and the retirement of Dr. Arthur W. Elting and Dr. John A. Sampson. Dr. Donhauser will succeed Dr. Elting as professor of surgery and as executive head of the college's department of surgery. Dr. Gorham succeeds Dean Ordway as professor of medicine and executive head of that department in the college. Dr. Ordway, who also resigned as dean, remains as professor of medicine and consulting physician at the hospital. Dr. Wallingford succeeds Dr. Sampson as professor of gynecology and executive head of the college's department of gynecology and obstetrics. Dr. Sampson will continue as professor of gynecology.

MISS J. P. ALLEN, superintendent of the Kingston City hospital, was elected president of the Hospital Association of North-eastern New York at its annual meeting in Poughkeepsie at Vassar Alumnae house on June 18. She succeeds M. M. Sutherland, woman superintendent of the Mary McClelland Hospital, Cambridge, N. Y. Dr. Charles Martin, medical superintendent of the Albany General Hospital, was elected vice president, and M. S. Dondale, secretary to the dean of the Albany Medical College, secretary-treasurer. The northeastern association held a joint meeting with the Westchester Hospital Association.

Speakers, who included Joseph J. Weber, superintendent of Vassar hospital, in charge of the meeting, stressed the importance of nursing education, in its relation to changing professional conditions. Dr. Henry T. Moore, president of Skidmore College, and Elizabeth C. Burgess, professor of nursing education at Teachers' College, Columbia University, were the chief speakers.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Personal Injury Action—X-Ray Examination of Plaintiff

A few months ago, the highest Court in one of the Southern states handed down a decision in an interesting case which is illustrative of the development of the law in requiring plaintiffs in actions for personal injuries to submit to x-ray examinations in proper cases.*

The plaintiff in the action was a seven year old girl at the time it was claimed she sustained the injuries in question, some two years before the case was actually tried. The defendant was the owner of a bus that had come into collision with a coupe in the rumble seat of which the infant plaintiff was riding at the time.

Various persons who were at the scene of the accident immediately or shortly after it happened testified upon the trial that the child did not seem to have been injured. The child's mother testified that the day after the crash she discovered bruises on the hip and stomach, and vaginal bleeding for some weeks. She also claimed the child had been confined to her bed during part of that time with a high fever. Concededly, however, no physician attended the plaintiff until about three months had elapsed, when a Dr. C. was consulted.

Doctor C testified upon the trial as a witness for the plaintiff, and described a condition of soreness in both hips and back when he first saw the child. He also testified that he found soreness and swelling in the groin, and a highly nervous and anemic condition. Doctor C later took a series of x-rays of the plaintiff which he produced in court, and which were exhibited to the jury. He stated that his interpretation of the x-rays was that the girl suffered from "green stick fractures of the left pubic bone and through the ilium leading down to the left hip joint, that there was a crushed left hip joint to the extent that it was out of alignment one-quarter of an inch, that the coccyx bone was fractured and pushed to one side." He also stated "when she grows up with this hip mashed in there, she is not going to be able to ever become a mother if this bone doesn't grow."

There was also testimony on behalf of the plaintiff that the normal activities of the child had been and would continue to be greatly limited. To controvert this the defendant put on the stand various neighbors and other persons who testified that since the alleged accident they had observed the plaintiff enjoying all the usual activities of a normal, healthy child, without showing evidences of any injury or disability.

The defendant called as witnesses three physicians who were experts in x-ray interpretation and one of whom was an expert radiologist. These doctors each testified upon examining Doctor C's x-rays they were so defective as to be of little or no value. They charged that the x-rays showed no evidence of any injury. They each stated that the films showed that one hip was higher than the other, but that it was not due to a deformity but rather to the improper position of the patient when the pictures had been taken. It was also stated by the said experts that the x-rays showed that the patient had not been properly "centered," and that the pictures had been taken at an angle causing a distortion.

No physical examination of the plaintiff had been made by any physician representing the defendant before the trial as is frequent in such cases in this State, there being no specific statute in the jurisdiction to authorize such procedure.

During the course of the trial the Court permitted the plaintiff's hip and abdomen to be exhibited to the jury in presence of the trial Judge and counsel in the jury room. As that was being done, the mother testified that there were bruises on "her little stomach here" and that a certain scar had not been on her hip before the accident.

Immediately after returning to the courtroom defendant's counsel made an application to the Court for permission to have a physical and x-ray examination of the child made by disinterested physicians. No consent was given to the proposed examination, and the application was denied.

The jury returned a verdict in favor of the plaintiff in the full amount demanded in the complaint.

**Dixie Greyhound Lines v Matthews*, 170 So 686.

The defendant took an appeal from the judgment, assigning as error the refusal of the Court to grant the requested physical examination. The Appellate Court ruled that under the circumstances the ordinary immunity against physical examinations no longer existed, and that the judgment should be reversed by reason of the erroneous refusal to permit the desired examination. In so ruling the Court said

X-ray pictures of the parts of appellee's body which were claimed to have been injured in the accident were produced before the jury, and the correctness, accuracy and sufficiency of these pictures were sharply controverted, and the alleged injured parts of her body were voluntarily exhibited to the jury. This being true, upon authority and what we consider the better reasoning, we have reached the conclusion that thereby appellee's personal immunity from examination by experts was waived, and that under these circumstances the supposed injured parts which were exhibited to the jury thereby became subject to a reasonable and proper x-ray and physical examination by experts of the defendant's selection, under such reasonable restrictions as the court might require. The court would not be required to, and should not, grant the right to an examination that would involve unreasonable delay of the trial, and in granting the right to such an examination should preserve the injured party's right to have his own medical and legal representatives present at such examination.

It should be noted that in New York State, Section 306 of the Civil Practice Act provides as follows

Physical examination In an action to recover damages for personal injuries, if the defendant shall present to the court satisfactory evidence that he is ignorant of the nature and extent of the injuries complained of, the court, by order, shall direct that the plaintiff submit to a physical examination by one or more physicians or surgeons to be designated by the court or judge, and such examination shall be had and made under such restrictions and directions as to the court or judge shall seem proper. If the party to be examined shall be a female she shall, if she desire, be entitled to have such examination in the presence of her own personal physician and such relative or other person as the court may direct. The order for such physical examination, upon the application of the defendant, may also direct that

the testimony of such party be taken by deposition pursuant to this article.

The courts of this State have held that in proper cases a physical examination under the said section may include an x-ray examination

Claimed Negligent Treatment of Infant

A physician who specialized in ear, nose, and throat work was called to attend a five months old baby. He found the child to have a temperature of 103°F and a swelling of both sides of the neck. Both ears were congested as well as the throat. He prescribed a medicine for the fever and drops for the ears. A few days later he incised both ears and released pus. Three days later the doctor drained the ears with a suction tube and again when he was called at night, (the second day after the said treatment), he found the child gasping for breath. His diagnosis after examination was a peritonsillar abscess on the left side, which he immediately incised. The next day the child's mother reported the child had become apparently worse and he directed that the child should be taken to a hospital specializing in the care of infants. The doctor, later in the day, communicated with the house physician and ascertained that the child had been admitted to the hospital and was being taken care of. He never saw the child thereafter and later learned, that about a week later, the child died, the cause of death being given on the death certificate as peritonsillar abscess contributed to by laryngeal edema.

A malpractice action was instituted against the doctor charging that he had been negligent throughout the care of the child and specifically charging that he had used unsterile instruments in connection with the surgery which he had performed. It was claimed that said alleged negligence caused the baby's death.

The plaintiff's attorney made repeated attempts to obtain an offer of settlement from the attorney for the defendant doctor and when he was finally convinced that no settlement of the case would be made he stipulated to discontinue the action.

Because of the equivocal results attending the use of pertussis vaccine for the prevention of whooping cough, and the difference of opinion still existing concerning the value of such prophylactic injections, the New York City Department of Health has decided to limit its administration of the vaccine to a carefully controlled experimental project now being carried on

under the direction of Dr. Ralph Muckenfuss, Director of Laboratories at the Williamsburg-Greenpoint health center and at the Prospect Clinic in Brooklyn. Heretofore the vaccine was administered on request at all the Baby Health Stations. This practice will now be discontinued. Through the experimental project the Department hopes to arrive at definite conclusions.

Across the Desk

"The Salt of the Earth"

THE LATEST WRINKLE IN FACTORY management, it seems, is to have supplies of common salt here and there around the plant, so that workers who become overheated can take a pinch now and then, or a drink of cold salt water, to avoid heat prostration. The pinch of salt prevents heat stroke by supplying more NaCl for the briny sweat of honest toil. The *Roche Review* says that some manufacturers also set out a supply of gum drops or other candy, along with the salt, to make good the body's loss of sugar.

A Matter of Life and Death

So salt, made of two deadly substances, is essential to life. Either one, taken separately, will bring death, but if we do not take them in combination, that brings death too. It is like other deadly poisons, such as arsenic and hydrochloric acid, that help sustain life when used rightly, and snuff it out when used wrongly. Our whole system, we might say, floats in a briny saturation, and whether we sweat, weep, or bleed, we prove that we have within us, from top to toe, "the salt of the earth." By the salty sweat of man, he wins from the world all its rich products of field and stream, the gold from the mine, the jewels from the mountain, the pearls from the sea, the furs from the forest, and by the briny tears of woman she wins them away from him for her personal use and adornment.

Why and how the human system became so impregnated with chloride of sodium is an intriguing question. Some scientists have hazarded the guess that the strangely persistent bodily temperature of 98.6°, alike in the Arctic and in Africa, traces back to our aquatic ancestors who floated for eons in seas of that temperature. Well, if science is to leave the solid ground of fact and leap lightly off the springboard of fancy like that, nothing prevents us from doing the same, and we can suppose that our fishy forebears, in their eons of salt-water bathing, became so used to it that we still have to have our systems full of brine. But was the ocean as salty in those days as it is now? True, the great salt deposits in vari-

ous parts of the world are supposed to be the beds of old seas that have dried away, but how did the old seas get so salty? Was the salt brought down to them by the rivers? Which had it first, the sea or the land? It is like the old riddle of which came first, the hen or the egg. It is anybody's guess, and perhaps the little girl's explanation is as good as any—that the ocean is salty because it has so many codfish.

Of course the statistical sharps would have a crack at this subject, and one of them figures that the entire ocean, if dried up, would yield no less than four and a half million cubic miles of rock salt, or about 14½ times the entire bulk of the continent of Europe above high water mark. As *Punch* would say, "Why don't they do it then?" Another suggestion might be that statisticians who have nothing more useful than this to offer might also just as well dry up.

A "Case Report"

A prominent New York doctor used to tell the story of a society woman he was called in to treat who turned out, upon examination, to have a serious deficiency of salt. She had had a series of the so-called fashionable practitioners who had given her this and that, without avail. Dr. C sized his patient up psychologically as well as physically, and was certain that if he told her she needed salt, she would merely sniff loftily and change doctors again. So he wrote prescriptions for liquids, capsules, and pills of various colors, flavors, and sizes, all of them containing basically the same stuff that was in the lady's salt-shaker. She made a fine recovery, swore by Dr. C, and always kept his prescriptions at hand.

"Ye are the salt of the earth," was a biblical compliment paid to the faithful, and we see reflected here an idea of the precious quality ascribed to the now humble and common sodium chloride. We are the salt of the earth if we have something of salt's flavoring and preservative powers, and salvation itself is derived from *sal*, or salt, which saves things from decay and corrup-

tion Our salary is the old Roman *salarium*, or salt-money "We have some salt of our youth in us," wrote Shakespeare in "Merry Wives of Windsor," as if foreseeing another wife of Windsor and perhaps explaining why she captivated him A bit of delving into the glamorous past shows that salt even played an important role in early commerce and religion Nations which did not have access to the sea or to salt deposits had to resort to unusual means to obtain it. Aristotle tells of people who got it from the ashes of saline plants, and Tacitus and Pliny tell us that it was obtained in some parts of Germany, Gaul, and Spain by pouring the waters of brackish streams over fires of saline wood and collecting the ashes Homer calls salt "divine," and Plato says it is "dear to the gods" A salt spring was venerated by inland peoples as a gift from heaven, and the Germans waged wars for saline streams and believed salty soil sacred

Symbol of Faith and Friendship

Covenants were made over a sacrificial meal containing salt, we are told, on the idea that salt has a preservative quality and hence would insure an enduring and faithful compact "A covenant of salt" is mentioned in Holy Writ (Numb XVIII, 19) It is, in fact, difficult to escape the conviction that with the fading of such old beliefs, our manners and customs have lost much of the colorful symbolism that graced other days Among older peoples every meal having salt had a sacred character and created a bond of piety and friendship between hosts and guests

Even now this idea obtains in the Orient "There is salt between us," say the Arabs, and the Persians call disloyal and unfaithful friends "untrue to salt" "A man must eat a peck of salt with his friend before he knows him," says Cervantes in "Don Quixote." Salt as a means of better acquaintance also seems to figure in the superstition of childhood that you can catch a bird by sprinkling salt on its tail Such references, which might perhaps be continued indefinitely, at least show how deeply this common condiment, which we think so little about, has entered into the life and literature of the race

What the Sheiks of Araby Wanted

The popular fancy of the old caravans that wended their way across the plains and

among the mountains of the ancient world pictures them laden with spices, silks, gold, and rare jewels That is all very fine, and is good stuff for the poet and the storyteller, who have to have that sort of thing or else have no poem and no story But the cold, hard fact, it appears, is that the old caravan routes were created mainly for traffic in salt. When some Sheik of Araby captured a caravan, it is possible that his coffee-colored followers yelled loudest when they found the camels carried a good load of NaCl One of the oldest roads in Italy is the *Via Salaria*, which brought sea salt from Ostia to the Sabine country The Latin word for health, *salus*, is more than half *sal*, or salt, and from it we get "salubrious," "salute," and many other words of good omen Heroditus tells of caravan routes to the salt oases of the Libyan desert, and we are told that even today the caravan trade of the Sahara is largely a traffic in salt. The vast salt mines of northern India were worked before the time of Alexander

We little realize the wealth of romance and even tragedy symbolized in the tiny salt-shaker we finger so lightly at the breakfast table Well within the memory of some of us European governments levied heavy salt-taxes, set up salt monopolies, and barred the very peasants along the seashore from boiling the water to get its precious mineral Many a time the crack of the coast guard's carbine felled some father trying to secure for his family that precious substance—salt The richest nations in the world are now looking hopefully to the time when they can return to the use of gold as money, something that is of no possible value in sustaining life or health, except perhaps to fill the aching void in a decaying tooth In some of the wilder parts of Africa and Asia, however, cakes of salt circulate as cash, thus neatly combining monetary and actual value Banks wishing to keep their assets liquid would merely have to add water There is perhaps an idea for our starry-eyed geniuses of the Washington "brain-trust"

The sting of the compliment to the faithful lies in its tail They are the salt of the earth, "but if the salt hath lost its savor, wherewith shall it be salted?" Pure salt, of course, never loses its savor Loss of savor means that the real salt is overcome by impurities The lesson to all of us is too obvious to need any elaboration

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

A Handbook on Diseases of Children Including Dietetics, Welfare and the Common Fevers By Bruce Williamson, M.D. Second edition 16mo of 329 pages, illustrated. Baltimore, William Wood & Company, 1936 Cloth, \$4.00

Here is a handbook that fulfills all the requirements the reviewer has desired in such a book. The author jumps from the preface directly into the middle of Respiratory Diseases which are the most important group in respect to children. An excellent discussion of the fundamentals for the understanding of disorders of the heart follows and from there on the subjects are taken up in the order of their importance. No words are wasted, no unnecessary subject is discussed, the results of the latest in medical thought are applied and throughout is appreciated the editorial guidance of the author. The book is really delightful giving one the impression of discussing the matter with an eminent specialist rather than of reading a textbook. The usual practical helps in respect to formula making, tables of weight-height standards, norms of development and the use of drugs are included. The chapter on tuberculosis could be improved upon.

KENNETH G JENNINGS

Handbook of Orthopaedic Surgery By Alfred R Shands, Jr, M.D. Octavo of 593 pages, illustrated. St Louis, The C V Mosby Company, 1937 Cloth, \$5.00

The author has accomplished the purpose for which the book was written. It is probably the best recent book on orthopaedics for the use of medical students and general practitioners.

The description of the various subjects are short, concise, and sufficient in detail. The description of many rather rare orthopaedic conditions are left out, and perhaps wisely, since it is not intended as a reference book. It is the reviewer's opinion that inclusion of a short description of proper technic and common orthopaedic apparatus would enhance the value of the book, even for the medical student and general practitioner.

The pen and ink drawings are excellent as far as they go but they are rather in-

sufficient in number. The description of some of the lesions should be clarified by the use of more illustrations.

JOSEPH B L'EPISCOPO

Ophthalmoscopy, Retinoscopy and Refraction. With New Chapter on Orthoptics. By W A Fisher, M.D. Fourth revised edition. Duodecimo of 210 pages, illustrated. Chicago, H G Adair Ptg Co, 1937 Cloth, \$2.00

A handy book of 210 pages that should be useful to students of ophthalmology. The methods of using the ophthalmoscope are explained and a number of small but very good colored plates (24) give an excellent idea of the more common variations of the fundus picture found in disease. Retinoscopy and refraction occupy 84 pages with many useful diagrams and many practical hints. The final 31 pages are devoted to orthoptics giving the opinions and technique of various authors without committing the author to any definite conclusion.

This is the fourth edition of this book and the accent is always upon the practical.

RALPH I LLOYD

Heart Disease By Paul Dudley White, M.D. Second edition. Octavo of 744 pages, illustrated. New York. The Macmillan Company, 1937 Cloth \$7.50

The value of this book needs no comment as the first edition proved to be the most authoritative present-day textbook on heart disease published. This edition has been slightly shortened by a reduction in description of methods of examination, and by curtailing the bibliography. It seems a pity to reduce the latter, as this was one of the valuable features of the book for the advanced student. However, all the key references are given, so that the book still retains this feature. The general arrangement is the same as before and two new appendices have been added, one giving the chronological order of the development of knowledge regarding heart disease, and the second the classification of cardiac diagnosis approved by the American Heart Association. The book should be in the possession of all interested in diseases of the circulation.

J HAMILTON CRAWFORD

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W 42nd St N Y C.) postage prepaid. Order must be accompanied by remittance covering published price.

NONSURGICAL TREATMENT OF PYLORIC OBSTRUCTION RESULTING FROM PEPTIC ULCER

Based on a Series of Patients Observed from Three to Ten Years

HENRY A. RAFSKY, M.D., F.A.C.P. *New York City*

Attention has been directed to the fact that patients with pyloric obstruction, resulting from peptic ulcer, may be successfully treated by nonsurgical measures.¹⁻⁶ There is, however, one phase of this subject, which has not been sufficiently emphasized, namely, the question as to whether the medical treatment will stand the test of time, when applied to ulcer patients with a severe degree of stenosis. It was therefore thought of interest to report a group of cases with marked pyloric obstruction, resulting from peptic ulcer, which were treated by nonsurgical measures and which were observed for a period from three to ten years.

The present study comprised a series of twenty-six cases, nineteen of whom were males and seven females. A duodenal ulcer was present in twenty-four and a gastric ulcer in two. The ages of the patients, when they first came under observation, ranged from twenty-seven to sixty-nine years. The diagnosis of pyloric obstruction was made by the clinical history, laboratory findings, and roentgenographic evidence of gastric retention six or more hours after a barium meal. In eleven patients there was also a twenty-four, in two patients a forty-eight hour, and in one patient a seventy-two hour gastric residue. At the beginning of the treatment it was almost impossible,

at times, either clinically or roentgenographically, to differentiate between the inflammatory type of pyloric obstruction, which was amenable to medical treatment and the cicatricial stenosis, in which surgery was required. The therapeutic test had to be applied in order to make this distinction.

Therapeutic Methods Employed

The nonsurgical measures which were employed, in the patients under study, were as follows:

1 Ambulatory method A gastric lavage of warm water was given every day then every other day, and subsequently less frequently as the patient improved. Eight ounces of milk, one half an ounce of sweet cream and one dram of sugar were given every two hours. One-half an ounce of olive oil, twice daily, was also prescribed. Then two raw eggs or egg-nogs were added. This diet was kept up for five days. At the beginning of the sixth day two ounces of cooked cereal and three eggs were allowed. On the eighth day four ounces of cereal and two ounces of pureed vegetables were given. On the tenth day the patient was instructed to take four eggs, toast was permitted on the twelfth day. The diet was further increased if the lavage return and the radiographic findings continued to show improvement. Atropine sulphate grain 1/120, twice daily and an alkaline powder

consisting of five grains each of magnesium oxide and sodium bicarbonate or five grains of magnesium oxide and thirty grains of bismuth subcarbonate, or the following resorcinol mixture were prescribed

		Gm or Cc	
R Resorcinol	2		Z ss
Magnesium oxide	4		Z i
Acacia	qs		q s
Distilled water	180		Z ii

M Sig One-half ounce three times daily

Nonspecific protein therapy was also employed

2 Rest in bed This plan was carried out either by means of the Sippy dietetic régime or by duodenal alimentation. In the former, the medication as described above and gastric lavages were used. The duodenal feedings consisted of eight ounces of milk and one half ounce each of sweet cream and sugar, which were given every two hours. Five hundred cc of a five per cent glucose solution were instilled into the duodenum twice daily. Vitamins B and C were also added to the duodenal feedings three times a day. The above medication was likewise prescribed.

The improvement was checked by means of the lavage return, the roentgenographic findings, and clinical progress. Usually a trial of four to six weeks was sufficient to determine whether medical treatment would prove successful. In patients in whom duodenal alimentation was attempted, the fasting gastric aspirate aided in determining the amount of gastric retention. The duodenal tube was also employed as a means of determining the presence of an inflammatory or a cicatricial stenosis. As a general rule, if the metallic bead did not enter the duodenum in seven to ten days, the case was regarded as a cicatricial obstruction, in which surgery was indicated.

Results

Ten patients were treated by the ambulatory method, five by the Sippy plan, and eleven by duodenal alimentation. Twenty of the twenty-six patients (76.9%) are still comparatively symptom free. Four of the patients required further intensive therapy after one year, three after three years, two after four years. Eleven patients did not require

any further course of treatment for a period of five to nine years.

The degree of obstruction, as evidenced by the clinical and roentgenographic findings, did not bear any definite relationship to the successful outcome of medical treatment. In fact, in this series, the patients who have been symptom free the longest, appeared to have the most pronounced degree of gastric retention.

Six of the twenty-six (23.1%) patients had to be operated upon. Four of these patients were apparently well for three years and two for four years. In two of the patients, gross hemorrhage ushered in the return of symptoms. One of the six patients, in whom surgery was required, succumbed to a postoperative hemorrhage. This patient was operated upon at another institution. One patient developed a lobar pneumonia twenty-four hours after operation and although he was very ill, he subsequently recovered and has been well ever since.

The following case reports will illustrate some of the varied clinical aspects which were observed.

Case Reports

CASE 1, which was under observation the longest period of time, illustrates the result of treating a patient by the ambulatory method.

I G, thirty-seven year old male, was first observed October 15, 1926. His history, treatment, and follow-up for a period of five and one-half years were previously reported.⁴⁻⁵ The patient came to the clinic again on November 14, 1934, complaining of rectal bleeding which was due to hemorrhoids. Otherwise he felt well. If he did have heartburn, which occasionally he had, he relieved himself by gastric lavage. He took the alkaline powder whenever he was constipated. He was again seen on June 1, 1936, at which time he stated that he was in excellent health until three days ago, when after eating clams, he began to have abdominal pain and vomiting. He was treated at the clinic by means of a liquid and semi-liquid diet, antispasmodics, gastric lavage, and small doses of alkali. He was discharged on June 13, and he has remained symptom free. An x-ray taken on May 14, 1937 did not reveal any gastric retention (Fig 1).

CASE 2, which was treated by duodenal alimentation, also illustrates the method,⁷ which facilitated the passage of the tube through an occluded pylorus

M L, fifty-nine year old female, was first observed August 7, 1933. She gave a history of periodic attacks of abdominal pain for twenty years. Three months ago the pain became worse and she began to vomit. She also complained of dizziness and weakness. She lost ten pounds in three months. Physical examination revealed an atonic and dilated stomach. The gastric contents showed HCL, 60, acidity, 75, blood, positive, lactic acid, negative, Sarcinae, positive. A diagnosis of an obstructive ulcer was corroborated by an x-ray examination. An attempt was made to treat the patient by means of duodenal alimentation but the tube did not enter the stomach in seven days and surgery was advised. The patient refused to be operated upon. A bead 14F, covered with gauze was attached to the metallic tip, by means of twenty-five cm of English silk #6 (Fig 3). Three days after these were inserted it was possible to institute duodenal alimentation, which was continued for three weeks. The patient made an uneventful recovery and has been symptom free ever since. (Fig 2)

Cases 3 and 4, illustrate the effect that physical exertion or trauma may exert in these patients, irrespective of how long or how short a period they may be symptom free

CASE 3 E A was first observed April 7, 1932. He gave an ulcer history of two years' duration. An x-ray taken on June 4, 1932, showed a marked six hour gastric residue. The patient was treated by duodenal alimentation and was symptom free until December 10, 1935, when, after vigorously shoveling snow, he was seized with a gastric hemorrhage. He recovered from this attack and came back to the hospital on February 3, 1937, for another course of duodenal alimentation because of slight epigastric pain and because he feared that he might have another hemorrhage

CASE 4 J D, twenty-eight year old white male, was first seen April 27, 1932. He gave a typical ulcer history of two years duration. A roentgenographic examination on May 19 and 20, 1932, showed an obstructive ulcer with a six and twenty-four hour gastric retention. He was treated by the ambulatory method and on June 28, the x-ray showed no evidence of a gastric residue. He was symptom free until August 25 when he was brought to the hospital with the history that on the

day of admission he had been operating a floor polishing machine for six and one-half hours. On one occasion the machine became stuck and he pushed it very hard with his abdomen. He broke out in a sweat and collapsed. The patient was operated upon and there was found, what the surgeon stated was the "largest perforation" he ever saw. It was located on the anterior surface of the stomach. A simple closure was done at that time. The patient was readmitted on October 3, for a cicatrized pyloric stenosis, when a posterior gastroenterostomy was performed. He has been symptom free ever since.

CASE 5, while not included in this series, illustrates the most recent case in which the therapeutic test was applied to differentiate an inflammatory from a cicatricial obstruction

J M, twenty-five year old male, was first observed March 4, 1935. He gave an ulcer history. The roentgenographic examination revealed an obstructive peptic ulcer with a twenty-four hour gastric residue. He was treated by the Sippy plan and was discharged symptom free on May 8. He felt well until he began to "eat everything" and in February 1937, started to vomit food which had been ingested thirty-six to forty-eight hours before. On April 2, the x-ray examination revealed a constant scarring of the duodenum, with a gastric residue similar to that observed in March 1935. The question arose as to whether we were now dealing with an inflammatory obstruction or a cicatricial stenosis. The patient was given the therapeutic test. The Sippy plan was used. He again became symptom free and on May 26, only a trace of barium was present at the end of six hours. He was last seen on June 21, having gained in weight and feeling very well. He was cautioned to be careful about his diet and to avoid mental and physical strain if he wished to escape surgery.

Alkali Therapy in Obstructive Peptic Ulcer

It is a clinical fact that the administration of excessive doses of alkali in ulcer patients with or without pyloric stenosis is not infrequently followed by an increase in the carbon dioxide combining power of the blood plasma and a decrease in the blood chlorides. It has also been pointed out that patients with pyloric obstruction, resulting from a peptic ulcer, are potential cases of alkalosis.⁶ It

was, therefore, deemed advisable to treat the patients in the present series, with comparatively small doses of alkali. This plan of therapy proved very satisfactory, notwithstanding the fact that no attempt was made to bring out acid neutralization. The secretory response was not used as a therapeutic guide. It was interesting to note that in most of the patients, the acid curves and the clinical response did not seem to bear any definite relationship to each other. In determining the gastric acidity, after histamine, similar acid curves were observed, in most of the patients, before and after treatment. Some of the patients, in whom surgery was required, revealed a similar or even less of a secretory response than other patients who were successfully treated by medical means. Fig 4 will illustrate this.

Discussion

A series of patients with pyloric obstruction resulting from peptic ulcer and treated by nonsurgical measures were observed for a period from three to ten years. The methods which were employed and the results obtained have been outlined.

In treating patients with an obstructive peptic ulcer, one must bear in mind, that it is impossible, at times, to differentiate between the inflammatory type of stenosis as a result of edema and congestion due to a probable antral gastritis and a mechanical obstruction due to cicatrization. The therapeutic test may have to be applied to make this distinction. It is a clinical fact, however, that the more edematous the pyloric outlet is, the better the chances for medical improvement, the more cicatrized the pylorus is, the more gratifying the ultimate postoperative results. During the acute obstructive stage it may not be possible to definitely outline the ulcer. When the edema and congestion have subsided the deformity may then be observed (Fig 1, A and C and Fig 2, A and C).

While the ambulatory method and the Sippy plan have been successfully employed in the nonsurgical treatment of obstructive peptic ulcers, the use of the duodenal tube was advocated whenever possible. The reason for this was that

the duodenal tube, with the bead attached, had a prognostic as well as a therapeutic value. It enabled us to decide much more quickly with which type of obstruction we were dealing. The following case report will illustrate this fact.

CASE 6 C K, forty-two year old white male, was operated upon three years ago for a perforated ulcer. He was symptom free until three weeks ago when he com-

Fig 3 Duodenal tube with bead attached, *in situ* (Case 2)

plained of epigastric pain, heartburn, belching, and constipation. The diagnosis of a duodenal ulcer was confirmed by x-rays which did not reveal any six hour gastric residue. An attempt was made to treat the patient with duodenal alimentation. Although the roentgenographic examination did not show any six hour retention, the tube with the bead attached did not enter the duodenum in seven days. Surgical intervention was advised. The patient was operated upon January 23 1937. The operative findings were as follows: The pylorus was patent, although numerous adhesions from this region to the liver, gall-bladder, and the omentum were found which may well have caused some degree of mechanical obstruction. A moderate sized area of induration was found in the posterior wall of the first portion of the

Fig 4 (A) Secretory response after histamine, January 20, 1937, chief complaints were slight epigastric pain, heartburn, and vomiting. Posterior gastroenterostomy performed January 23. (B) Secretory response after histamine, May 20, 1937. Patient successfully treated by nonsurgical measures and has been over ten years. Patient is still symptom free. (C) Secretory response after histamine, May 26, 1937 during acute exacerbation of symptoms, chief complaints were severe abdominal pain and vomiting. Posterior gastroenterostomy performed June 1.

duodenum, two cm from the pylorus. A posterior gastroenterostomy was performed.

In this series of patients, excessive alkali therapy was not employed. By using comparatively small doses of alkali in these obstructive ulcer patients, good results were obtained and the danger of alkalosis was avoided.

The factors which seemed to favor recurrences in some of the patients were dietetic indiscretion, mental or physical strain, and trauma and respiratory infections, though seemingly mild. Hence, ulcer patients must be impressed with the avoidance of these, in so far as it is possible.

In patients with pyloric obstruction, resulting from peptic ulcer, the possibility of malignancy must be considered. In duodenal ulcers this disease is not as frequently encountered as in gastric ulcers. It is beyond the scope of this paper to enter into a discussion as to whether these ulcers are malignant from their inception, or whether they subsequently undergo this change. In obstructive gastric ulcers, especially those located in the

prepyloric region, it is very difficult, at times, to definitely rule out the presence of malignancy. Recently, one of these cases was observed in which a distinction between benignity and malignancy of the stomach could not be made at operation. It is also a clinical fact that these malignant affections may even show temporary symptomatic improvement after medical treatment. In doubtful gastric lesions, a careful history, the secretory response after histamine, a gastroscopic examination in addition to a roentgenographic study, will prove to be of invaluable assistance in establishing the diagnosis and course of treatment. This aspect will be more fully discussed in a future article.

Summary

1 A series of twenty-six patients with obstructive peptic ulcers, treated medically, were observed from three to ten years.

2 Twenty patients (76.9%) are still comparatively symptom free.

3 The nonsurgical measures which were employed have been outlined

4 Acid neutralization was not neces-

sary to bring out clinical and roentgenographic improvement

ARE MEDICAL SOCIETIES CANCER-SHY?

Medical societies are criticized by the Division of Cancer Control of the State Department of Health for their indifference to the problems of cancer treatment. In its twenty-sixth annual report the division observes that lay groups are willing to attend lectures by staff members trained in cancer research, prevention, and cure, but—

"The medical societies are rather reluctant to devote some of their meeting time to the discussion of cancer. It is a recognized fact that cancer perhaps does not enter into their economic problem as much as some of the other diseases, yet cancer ranks second as the cause of all deaths and demands more time from the profession than it is receiving at present."

Efforts to interest professional men and women in the disease have failed dismally, according to the report.

"Two courses were given during the past year at county medical societies, one in conjunction with the Erie County Medical Society and one with the Monroe County Medical Society," the report stated further "The courses were in the nature of an experiment. The courses were offered free of charge to any physician and covered the entire cancer problem. The lectures were illustrated by lantern slides and, in some cases, by actual specimens

"It was the original intention to extend these courses to other comparatively large centers of population, if they proved successful at first.

"However, we were disappointed at the attendance at these lectures, again demonstrating the fact that the practicing physician is not greatly interested in the subject of cancer. Out of a possible 1,000 physicians in Erie County the average attendance was only 30 and in Monroe County the average was about 40. Unless there is a decided demand, these courses will not be continued."

Lamenting the fact that general practitioners will not attend meetings devoted to cancer, the report continued

"We hope, by circularizing the medical profession with short pamphlets on the essentials of the cancer problem as it relates to the medical man, and also by calling attention to his moral responsibility in reducing the mortality, to impress upon him the fact that the fate of the cancer patient is in the hands of the first doctor who sees him."

To counteract the indifference of physicians and dentists, the division has been compelled to resort to lay education.

"We believe popular lay education," said that part of the report prepared under supervision of Dr. Louis C. Kress, "presented in a manner that is most attractive and that the average person will understand, will have great influence in suppressing this disease because it is a known fact that early cancer in most instances responds more readily to treatment than does the far-advanced type."

One of the major purposes of the lay education program will be to allay the fear of cancer. So widespread has the dread of the disease become, that the state will be forced to take steps to circularize authentic information on the problem.

Dissemination of knowledge on cancer to the general public will be the major task of 1937, in the opinion of those entrusted with directing the state's campaign against the disease, the pamphlet reported.

"More consideration must be given to lay education, especially in the rural districts where the advantage of lectures on medical subjects is not usually available."

In addition to the lectures, exhibits will be given throughout the year at county fairs, high schools, colleges, farmers' meetings, luncheons, church and study groups of both men and women, fraternal organizations, voluntary firemen and members of home bureaus and granges.

Does a doctor doctor a doctor according to the doctored doctor's doctrine of doctoring, or does the doctor doing the doctoring

doctor the other doctor according to his own doctoring doctrine?—*Nebr State Med Jour*

SHADOWS IN THE MIRROR OF HEALTH

T WINGATE TODD, MD, *Cleveland, O*

*Developmental Health Inquiry of the Associated Foundations Anatomical Laboratory,
Western Reserve University*

In his *Natural History of Selborne*, Gilbert White tells of holding in his hand a stilted plover, a bird with no back toe and therefore, he writes, "liable, in speculation to perpetual vacillation"¹ This attitude of vacillation so characteristic of all peoples and governments since the War shows signs of giving way before constructive thought We have at least learned better how to deal with unemployment The boggy that public expenditure on relief is economically unsound has been laid Unemployment has been shown to be no respecter of nations but a world-wide disease whose remedy must be international The social services are more firmly based and more widely spread The great leisure movement with shorter hours and vacations on pay has steadily advanced We have gained some glimpses of new monetary technic and have abandoned some misconceptions on wage policy² There is a new outlook on how adults with their experience of the world should bring up boys and girls The citizen of tomorrow must be healthy and physically fit There is almost an international competition in devising systems to ensure that growing children shall become exemplars of manhood and womanhood³

Canon Paton-Williams reminds us that the people who make quarrels are not the healthy people People make quarrels when they are run-down, nervous, and on edge with emotion so pressed down that it must break up or break out Unless we provide for future generations an adequate means of liberating repressions in the strain of modern life, the future will be even darker than the present.

Sir John Simon points out that the ideal of physical fitness is not a bad ideal to add to those of honor, loyalty, and service Ideals are essential and must be firmly established in youth if we are not to build up a nation of crabbed, selfish, cynical citizens later on

Oliver Stanley speaks of three fundamental principles of education *First*, the

child is an organic whole *Secondly*, the teacher is no longer a person appointed to train or instruct children but a supervisor whose duty it is to promote the natural growth of his pupils *Thirdly*, environment is one of the most important factors in education.

In the new *Handbook of Suggestions for Teachers* there is the clear enunciation of a shift in emphasis in teaching from the subject to the child⁴ This means that the curriculum is dictated by the nature and capacities of the child and not by any preconceived code of regulations It means also that the subjects in the curriculum have changed in order of importance. Now health and physical training come first, then music and practical subjects, and lastly intellectual exercises and mathematics The order follows the development of the child, first the physical, next the concrete, and then the abstract. The teacher is the interpreter to his pupils of the world and of life as well as of knowledge

On one of the buildings of that great rock, the Acropolis of Athens, the city where Democracy was cradled and all men first stood equal before the law, there is the inscription "Athens of the Athenians, the Free" It was Athens inventing the notion of liberty in contrast to the totalitarianism of Asia, of Africa, and of the Peloponnese That it failed at length is no slur on the genius which framed the thought Great as was his passion for Egypt, my late Chief, Sir Grafton Elliot Smith writes in the epilogue to his book on *Human History*, "When man began to devise civilization he became entangled in the shackles of the theory of the State, which he himself had forged It remained for the Greeks to remove the shackles and to restore to human reason the freedom it had lost. Ever since then the history of the world has been a conflict between the nationalism of Hellas and the superstition of Egypt"⁵

It is the bane of liberalism that it does

*A Banquet Address of the Medical Society of the State of New York,
Rochester, May 25, 1937*

succumb from time to time to the totalitarian theory even as it has in many countries during these last twenty years. The contribution which Greece made to liberalism of thought was not native but was imported along with the God Apollo who entered the Greek Pantheon from the Unshapen Land in the bleak northwest, the road to which from Athens lay past Thebes and the Copaic Lake, up the Vale of Cephissus, beyond the peaks of Ceta and Pindus, over the rich Thessalian plains, the Thracian Mountains, the Ister river, and the dreary Scythian waste. Apollo was the Teutonic God Baldur, the god of the sun, of mental as well as physical light, the god of Medicine, of prophecy, of music, the god of civic constitution and of the flocks and herds, Apollo the clever, the young, the strong, and the free. Delphi was his shrine city and on the slope of Mount Parnassus hard by were built the oracle, the theatre, and the stadium for the god of light and medicine was also leader of the Olympian orchestra and chief of the athletes, the god at once of health and strength and social adjustment. It is well for us to remember this in these days when the ancient principle of life of which Apollo was the incarnation is once more emphasized as the ideal basis for the Children's Charter.

"The average person," writes Macpherson Lawrie, "is not particularly preoccupied with the fact that malignant disease may kill him, nor is he seriously concerned with death. It is not hardened arteries or damaged kidneys or diabetes which people dread. The average person does not think about his health. But he does think about the impression he will make, his social prestige, his capabilities, his ability to beat a neighbor at a game, his chances of promotion, and his appearance. And there are very few men and women of our acquaintance, whatever they may say, who, in their hearts, would not like to meet their social circle with a greater confidence, their occupation with more proficiency, their embarrassments with calmer self-assurance, their domestic life with more complacent certainty, and the world in general with that additional cheerfulness and vigor which renders life a vivid actuality rather than a passage of existence."¹⁰

Today also disease has changed. It no

longer slays ruthlessly in epidemics but insidiously cripples hearts, hardens arteries, ruins teeth, warps and stunts development, shatters nerves, and produces morbid moods and manners which destroy or cripple confidence, initiative, and efficiency.

We must not wait the establishment of actual structural defect or organic disease before we strike. But we as physicians must carry our campaign further so that we grapple with the early stages of disability the indications of which are lassitude, apprehension, and despondency.

All very well to speak like this, reiterating truths which each one of us will readily acclaim. But how can such a scheme be practical? How shall we lock the stable door when we are not summoned till the horse is stolen or at best the horse thief is already in the yard. Preventive medicine of the future must devise ways of reaching and solving the problems of community well-being before disorder creeps through the masses, blunting their initiative and enthusiasm, undermining self-reliance and determination, dulling their hopefulness and robbing them of fortitude, tolerance, and self-control without which no modern community can expect to prosper.

This cannot be done unless we, the physicians who hold the balance between social order and chaos, reeducate ourselves. Our training has been to recognize established disease mentally or physically detectable, the last grim stage of a tragedy which no longer can be averted but involves besides the victim himself those who are near and dear to him. This attitude of Medicine and Philanthropy is obsolete, it encourages suffering, it distracts attention from the inefficiency of the employed and fastens it on the unemployable, it exaggerates the importance of the simple-minded or the nervous wreck and ignores the restless, the discontented, the impatient, the tired, the lethargic, and depressed.

Our daily professional duties do not force this newer viewpoint upon us, they give us no experience or opportunity to exercise our alertness in inquiry as a rule. Nor will they till both we and the public clearly recognize the value of periodic examination and until that examination is changed from the routine clinical inspection of today for the systematic investiga-

tion of somatic health as well as of organic efficiency

We have been taught to think in terms of structural pathology and the inheritance of physical defect. Treatment has been adapted to the compensation of defect and the eradication of disabilities but our eyes are already set on the restitution of constitutional health before long continuance of morbid processes has resulted in permanent deficiencies of structure. This transference of attention means detection of disability in the earlier or chemical stage of disordered metabolism and a study of the inheritance of undue sensitivities to the food we eat, the air we breathe or the clothes we wear. Problems of immunology and of allergy thrust themselves upon us with ever-increasing insistence.

The vista of Child Welfare of the future is not to be seen in the mirage of the height-weight-growth basis fundamental heretofore but through a portal framed by freedom from specific sensitivities. Beyond this portal we shall see children endowed with potentialities of growth and protected by scientific understanding so that they do no droop or suffocate in that care which brings strength and freedom to others.

We are on the threshold of a new scene where familiar objects appear in new settings. Food which was meat and drink now reveals itself as nutriment or poison. Illness formerly judged by its active symptoms now discloses itself in its initial fatigued or finicky stage. Children with a hidden allergy hitherto struggled through situations at the cost of great constitutional strain which can be avoided by early recognition and care. This struggle was intensified by the failure to recognize the changing manifestations of allergy as age increases.

The 1936 report of the Mixed Committee of the League of Nations on the problem of nutrition asserts that in no country in the world does the whole population attain the physical standard desirable, so widespread is defective nutrition. Ignorance of diet is prevalent and even in the wealthiest countries defective, inadequate, and ill-considered nutrition exists. Essential protective foods are too expensive for working class families.⁷

One particularly well-conceived and statistically controlled inquiry has been

carried out on sixty-nine families in Newcastle-upon-Tyne in England. Of these thirty-eight were unemployed, twenty-eight employed, and three were widows' families.⁸ Some measure of selection was inevitable as families likely to be noncooperative were obviously avoided. The data from families which were evidently intelligent show little indication of generally extravagant buying or of serious decline in home cooking. All consumed fresh meat and all but one had fresh vegetables. All the employed spent thirty-six per cent more money on the purchase of food than the unemployed but the amounts of energy and protein obtained per penny spent were twenty-three per cent higher in the unemployed than the employed. The unemployed therefore purchased three nutrients at lower cost than the employed. The greater cost of food in the families of the employed seems to have been due to the purchase of cakes, fresh tomatoes, butter, fresh milk, bacon, and boiled ham.

Under these circumstances, no differences are to be found between the heights and weights of children and women in the several groups though the employed men were on the average 13.25 pounds heavier than the unemployed, a difference apparently resulting from muscular wasting accompanying lack of exercise rather than deficient intake. Thirty-two per cent of the women of unemployed families however were enemic as compared with four per cent of those in employed families.

It is evident that the conventional criteria based on structure, namely, height and weight are inadequate to express the deterioration of constitution consequent upon financial stringency. Evidence to be sought in the more refined and delicate chemical methods of detection of which the anemia diagnosis stands as the index in this inquiry. There is however another criterion, namely, that of mortality. An earlier record from Stockton-on-Tees shows a doubling of the death rate largely due to respiratory disorders in the new housing estates where the unemployed have to pay a rental approximately twice that in the old housing districts.¹⁶ This carries suggestive although not conclusive evidence of the effect on nutrition and health produced by forced expenditure for people on the poverty line.

Our problem is then not to be solved by reference to established criteria of bodily size, but by standards still to be developed having for their aim the measurement of tissue health. That we have indeed set out upon a program of tissue health is evident in recommendations now customarily made upon diet. The traditional diet, comprising meat, potatoes, bread, and sugar, has already been substituted by diets for fattening, reducing, active or sedentary occupations, diabetes, allergy, and high blood pressure. What is most urgently needed today is the construction of diets which return to each child those essential elements lost through avoidance of foods ascertained to be specifically harmful to that child. What we need is dependable experimentation on food building, food substitution, and food adjustment. Food building is necessary that optimum nutrition be obtained, food substitution peculiarly appropriate to ascertained sensitivity, food adjustment as the hidden sensitivity successively modifies its mode of expression.

It has been my good fortune, these past seven years, to make an intensive study of the growth and development of well children from cooperative families among Cleveland's economically secure citizens. This longitudinal study has been carried out under the combined auspices of several local and national Foundations, but the particular phase which absorbs our attention at the moment is presided over by the Cleveland Foundation under its Coulby Fund. This apparently anomalous devotion to the study of well children, of a Fund designed to assist the sick, crippled, and handicapped, requires a passing explanation. The decision of the Cleveland Foundation to carry on this work was the result of our unexpected and arresting discovery that these well children, all of whom are under the regular supervision of pediatricians of experience, suffer more or less from unheeded, unacknowledged or unrecognized handicaps which sap the constitutional strength, resistance or integrity although they do not express themselves in the well-recognized symptoms of established disease. Indeed, some of the children ultimately develop hay-fever or other definite disabilities, but the great majority display nothing more than feeding problems in infancy, seasonal fluctuations in weight,

vagaries of growth, mild persistent eczema, dry skin, hives, food idiosyncrasies, stuffy noses, repeated colds or emotional disturbances. Our serial examinations, methodically carried out over so long a period on this unchanging group of children, enable us to catalog the successive indications of interference with optimum progress in growth and development and in the maintenance of health.

We note that the child who has difficulty in adjusting to the diet of infancy develops eczema in his early months, becomes what is known as a wet baby before his first birthday, suffers from stuffy nose, resorts to persistent thumb sucking or other mouth habits and has adenoids removed during the preschool period, displays defect of vision, usually myopia or astigmatism, in the same phase of childhood, is recognized as highly strung and hyper-reactive, begins to lag in increments of height or weight, and may develop frank seasonal hay-fever ultimately extending to perennial disability. Yet such a child is not recognized as constitutionally sick. He may or may not impress his physician or even his parents as requiring active medical intervention. But he does not enjoy that full measure of exuberant health which is his birthright, and the long-continued subtle undermining of his health brings in its train difficulties of adjustment for which the remedy may be sought in forcible social contact by way of nursery school. In any case, his happiness is prejudiced in school as well as home, giving his parents constant anxious concern which often expresses itself in over-protection in evitably enhancing his social handicap. We must bring ourselves to realize that educators are dealing with organic substances, and where training and education fail, they fail not so much because of an inherent lack of brain capacity as because the child, perpetually at loggerheads with life, vainly kicking against curtailment, is yet deficient in that healthy vigor which would end his fancied restrictions and set free natural expression. Rebellion and misfit, vague dissatisfaction, and childish unhappiness are less due to original sin than they are to stuffy nose, deranged stomach, excessive fatigue or the emotional imbalance of sub-clinical sickness.

The objective criteria by which unacknowledged sickness of this type can be recognized require a study only to be car-

ried out by the serial examination which is undertaken frankly from the point of view of prevention and not imperatively required by the existence of actual disease

At each examination the child's progress as well as his current state of health is noted. This is done by ascertaining the increments of growth since the previous examination. Status in height and weight means little. A child may be tall or short, heavy or slender for his age. His deviation from average however may be due not to recent failure of adequate increment but to a poor start or to interruption of adequate progress long before and never compensated. The records of our statistician Miss Simmons, for example, show that sixty per cent of an exploratory group of our children shortest at birth are still shortest in stature at four years, forty per cent of those tallest born are still tallest at four years. These are fair figures allowing for the difficulty of measuring the newborn whose knees may or may not completely extend. When however the comparison is made between stature at eighteen months and five years, we find that eighty-five per cent of both sexes maintain unchanged their rating of being tallest or shortest. The idea of later compensation for a failure in increment during childhood is a hopeful one, but no reliance can be placed on the hope. Nevertheless, although the previous failure must be discounted, it does not follow that failure of increment need continue. It is reassuring to parents as well as to the physician to learn from the serial examination that growth, previously interrupted, is again continuing without hindrance. Growth indeed is an all-or-nothing principle, it is an effective and sensitive measure of health. Properly analyzed, it is seen to show interruptions of progress rather than changes in tempo in children who are definitely outside the normal range in stature. The achondroplast, for example, does not grow at a tempo different from that of normally formed children. Trunks grow at the regular rate but limbs, irregularly, at a quarter the normal rate. In cretins the rate of growth is diminished to approximately one half regular rate. Children who in later years show gigantism grow in trunk and limbs at a rate greater than normal, and those who eventually become eunuchoid grow at a rapid rate in limbs but at a very

low rate in trunk. Setting on one side these marginal members of the community, the growth rate in children is regular and practically uniform, interruptions being registered as scars, transverse line or scorings on the bones. The x-rays of their limbs made at these serial examinations show the interruptions and, growth being uniform in its rate, we can ascertain by measuring the distance of these markings on the bones precisely when each interruption occurred. They are the tall-tale evidences of temporary constitutional handicap, marking the winter of growth like the rings on trees.

But the x-ray gives us much more than the mere record of disturbances in growth. It gives us information on tissue health paralleling the well-recognized clinical criteria of organic efficiency now employed in routine health examinations. Since seventy per cent of the iron in the body is found in the blood, a blood examination gives a useful approximation of the iron content of the body.⁸ It is the x-ray however which gives corresponding information on the mineral store for ninety-nine per cent of the calcium of the body is maintained in the bones.⁹ While skill and experience enable us to hazard an estimate on minor fluctuations, a drop of twenty-five per cent in bone mineral is distinguishable at a glance on the roentgenograms. An x-ray of the hand should therefore always accompany a blood estimate of calcium and phosphorus for while the blood examination gives more or less accurately the amount of these minerals in transit, the x-ray enables us to assess the amount in store. An x-ray of the bones in the estimate of calcium is then the proper counterpart of a blood examination for the determination of available iron.

Muscular tone and the composition of subcutaneous tissue should not be left to the uncertain estimate of "turger" or even the calipers in the ACH index.¹⁰ A roentgenogram of the hand, especially a lateral roentgenogram, shows definitely the degree of density of muscular tissue. It is our experience that children with light muscular shadows fatigue easily. Accompanying proneness to muscular fatigue is proneness to mental fatigue with its inevitable restlessness, impatience, and irritability. Those children show a standing height perhaps twenty-five mm or even more less than

their horizontal length. Poor posture is due less to habit than to constitutional debility.

Subcutaneous tissue, whatever its thickness, which is the proper criterion of nutrition, should be clear in the x-ray. Density of subcutaneous tissue means water-logged conditions and edema from defective fluid metabolism. This is found in periods of active allergy, more particularly in sensitivity to food allergens ill-defined by the skin tests, but also accompanies severe pollen sensitivities. A roentgenogram of the elbow is best suited for estimates both on subcutaneous tissue and skin.

Skin in infancy is thin. It increases in thickness in later childhood and should be moderately thick in healthy young adult life, thinning once more in age. But always it should be clearly defined from subcutaneous tissue on the x-ray and its surface should be free from edematous wrinklings often found near the wrist.

Before we leave the x-ray, mention should be made of its value in assessment of the physical development of the child. This is a subject on which I have been speaking and writing for ten years and the final result of our ten-years study on the hand as a criterion of physical development is now in the Press under the title an Atlas of Skeletal Maturation. I will therefore pass lightly over this subject mentioning merely that no rule-of-thumb method of measuring carpal area gives the faintest reliability, whereas assessment of degree of ossification of epiphyses by reference to standard x-rays is a dependable guide to the progress of the child in his general bodily development or maturation.

Roentgenograms of the head taken by the standardized Bolton technic, devised by my colleague Dr Broadbent, permit one to measure accurately the growth of the face as well as development of teeth, and give information on adenoids, tonsils, auditory tubes, turbinates, and paranasal sinuses. Again I shall not do more than direct your attention to these opportunities now available for the accurate and quantitative assessment of tissue health and growth progress in the face as Broadbent and I have already published numerous articles on the subject.^{11 13} I would however emphasize the fact that, in infancy when the constitution is most susceptible to disturbance, it is

the face rather than any other part of the body which registers permanent damage through interruption of facial growth, a damage which shows little tendency to repair and is forever afterwards merely compensated by structural modification.

In the course of one address, already grown too long, I cannot do more than bring to your attention the increasing opportunities now at our disposal for early and clear appreciation of sickness, especially in childhood, while it is still masquerading as proneness to fatigue, a highly-strung emotional nature, vague respiratory or gastrointestinal weakness, non-fulfilment of intellectual potentiality, talents or powers of application, reduction of energy, poor weight gain, eye strain, sluggish mentality or unacceptable social behavior.

And having told you of these things, let me put up a plea on behalf of the children, now growing up in days of harassment and distraction, showing in their attitudes, their dispositions, and their physical structure those evidences of menace to their future health, their future happiness and future usefulness. Happy are we who grew up in those unhampered days before the War came to chill and constrict what it did not destroy. Let not our children be marred in their physical powers of resistance, in their application to duty, their balance of mind among conflicting attractions of dubious value. Some will extricate themselves, hardy souls, facing with a will the risk of taking a way of their own like Cinderella in *Barrie's* play with nobody to tend her, little Cinderella with her watering can carefully bringing up herself.¹⁴ Some will be brought perhaps by the more virile kinds of sport as near as they are ever like to come to the thrill of high adventure of the human spirit. Others will eddy in eddying dust all their days, blown round and round by adventitious gusts of sentimentalism and fashion.

In this aim we shall succeed if we are able to see the whole great vision with the mind at the instance of some fragment seen by the eye. "It is essential" as an old hero of mine, C. E. Montague,¹⁵ once wrote, "to graft upon the bodily sense of sight a special kind of imaginative energy, so that when the fit eye has gone as far as it can, its work is taken over and carried on without a break, so that, when later you try to

remember, you cannot say where physical perception stopped and where mental vision began—all you know is that between them they have left you the memory of expanses greater than bodily eye ever saw, and also

more urgently real than imagination alone could ever frame, this is the key of the garden "

"PEP PILLS" OF BENZEDRINE SULFATE

College students have been using "pep pills" of benzedrine sulfate to help fight off sleep and fatigue when preparing for exams, and the practice has spread so widely that warnings have appeared in *Time* and in various college publications telling of their dangers. Cases of collapse, fainting and insomnia have been reported to the college physicians.

Their effect is like whipping a tired horse, remarks the *Journal of the AMA*—the eradication of fatigue and the stimulation of mental activity cannot be produced for any appreciable period without subsequent periods of retribution. The *Journal* points out that benzedrine differs primarily from other sympathomimetic amines that are used primarily for their vasoconstrictor actions in the extent of its ability to produce certain effects on mood and fatigue. These differences make it especially important that the drug be used only under a physician's direction.

There is as little excuse for employing it to avoid fatigue and sleepiness during a temporary period of stress and strain as there is for using morphine to produce sleep after that period is over. Physicians in a position to do so may issue warnings of the danger of employing the drug in this manner. The druggist too has an opportunity to demonstrate his cooperation with the medical profession by refusing to sell the item except on prescription.

Unfortunately, at one of the university cities where the drug has been obtained it has been purchased principally from the drug stores of a large national chain whose owners are apparently more interested in

the immediate profit than in the ultimate effects on the purchase. The manufacturers, on the other hand, appear to be anxious not to have the drug fall into disrepute through misuse, since it has been presented for consideration by the Council on Pharmacy and Chemistry of the A M A.

Benzedrine sulfate thus becomes one more example of a drug which is useful in a limited field of therapeutics but which has been diverted to uncontrolled use by the public for related, but not similar, purposes. If the situation is to be remedied, and it certainly must be as soon as possible, the manufacturer, the druggist, the student health authorities, the college officials and the physicians must cooperate in preventing the use of this drug by students, who through ignorance may be harming themselves, at least temporarily.

It is chiefly the ignorant who try such self medication, not realizing that a drug can never substitute for knowledge or intellect. The drug is too new to pharmacology and experimental medicine to warrant any prediction as to possible permanent harm that may result from its continued misuse.

This drug is one of a group which is contraindicated in certain circulatory conditions, especially hypertension. Some persons have an idiosyncrasy to the drug, which makes its use by them inadvisable. Thus far the reports of difficulties encountered with the drug have arisen from two midwestern campuses. Physicians may well keep this drug in mind when encountering cases of fainting, exhaustion, and collapse.

THE EPILEPTIC SCHOOL CHILD

How may we Understand and Treat Him?

FREDERICK L. PATRY, M D, *Albany*

Formerly Psychiatrist, State Education Department, University of the State of New York

The purpose of this paper is critically to take stock of present-day practice in public schools relative to the understanding and handling of the epileptic child

The facts upon which the circumstances of this formulation evolve are derived from replies to a questionnaire sent to some forty school physicians of cities and villages in New York State. Nineteen replies were received and will form the basis for the opinions and facts concerning the epileptic child's present-day status as herein presented

By way of contrast, it is interesting to note the attitude of Wood and Rowell^a who in 1927 expressed a pessimistic attitude toward the outlook for the education of epileptic children in public schools. To their mind no epileptic child should be permitted to attend a regular school as they felt it would be demoralizing not only to the child but to others because of the need for competent supervision as well as the fears and hazards of other pupils. Moreover, it was their opinion that retaining an epileptic child in a public school made him unduly an object of interest which gave rise to self-consciousness and this was regarded as an excitant to seizures. These authors also envisaged the hazards of transportation to and from school as well as the lack of facilities for his care in the classroom.

In contrast to the above opinion of these specialists in school health education we find a marked shift in opinion and practice throughout the schools of our State. To the writer this seems all the more surprising since not long ago a superintendent of a State Institution for Epileptics expressed to him the opinion that every child so diagnosed as an "epileptic" should receive the advantages of institutional care and treatment. He felt that this was fairer to the child in view of a more understanding and trained personnel to care for his peculiar needs as well as from the standpoint of happy and effective socialization. This specialist was

somewhat pessimistic concerning the future communization of such children since deterioration seemed so imminent in most cases.

We shall first present the facts of the survey of nineteen representative city and village school systems (ranging in school population from 1,179 to 16,145—average of 5,862) in New York State in response to the following questions relative to epileptic school children during the past five years

- 1 Number of cases per year
- 2 Criteria for exclusion and exemption from school
- 3 Diagnostic criteria for epilepsy
- 4 Ways in which school cooperates with the family physician, hospital, and other treatment agencies
- 5 Medical methods of treatment
- 6 Educational methods of treatment.
- 7 Ways in which cooperation of parents is enlisted.
- 8 Criteria for institutionalization

The above collected data is summarized as follows

1 *Average number of cases per year per school-age population* during the past five years is seven per 10,000 (range 0-19%). This percentage, although statistically insignificant is from the standpoint of school management perhaps more distressing and a more acute type of problem than any other facing the school personnel. Likewise, from the point of view of the home with respect to expert advice concerning education, medical treatment, environmental care, and supervision, it is of quintessential importance.

The grade range of epileptic pupils extends from first grade to senior year in high school. The incidence of epileptics per grade has not been determined. The total number of epileptics at present in school in the above nineteen school systems is sixty-four, a rate of six per 10,000 or 0.6 per cent. The percentage prediction of epileptics, however, would indicate the presence of some seventy-eight instead of sixty-four epileptics at present recorded.

2 Criteria for exclusion and exemption of epileptic pupils from school are

1 Repeated seizures in school (Nocturnal seizures and others occurring in out-of-school hours seem to cause little concern as far as the school is involved, although parents will frequently bring such children to the attention of the school physician in order that their condition may be evaluated and counsel given.)

2. Severity of seizures is important as well as their frequency. Obviously, the petit mal attacks, from the point of view of classroom management, are less disturbing than the grand mal type.

3 Time of seizure. Those occurring in the morning and early afternoon are apt to be considered more troublesome than those taking place in the late afternoon or evening.

4 Intellectual ability at so low a level as to be unable to profit by public school instruction, even in special classes.

5 Difficulty in handling a patient during attack.

6 Too great an interference, danger, or injury to others.

Certain school physicians felt that it was unfair to exclude any pupil from school as long as there was no greater interference with the school routine. One city school had a standard for exclusion of two spasms or more per month. This same school system makes the practice of excluding all having an I.Q. below sixty-five who have frequent seizures. Certain schools were concerned about the efficiency of treatment in relationship to frequency of attacks. There was a tendency not to make a decision for exclusion until attacks were brought under competent medical treatment.

3 With respect to *diagnostic criteria* there was expressed a general wholesome reluctance to make the diagnosis of "epilepsy" until the suspected child had been examined by the family physician or a specialist in psychiatry or neurology. Although at times the only description of the attack was that which could be given by the classroom teacher, yet every attempt seemed to be made by the school physician to see the child in such a condition himself. Loss of consciousness was considered essential for the diagnosis of epilepsy although in the petit mal type the momentary nature of the absent look and vacant stare puzzled the untrained observer, thus confusing this illness with behavior problems such as day dreaming, inattention, and lack of cooperation. The Medical Inspection Law is expressed in the following school physician's statement, "We do not diagnose or treat in school, except in cases of accident or emergency."

In certain cases, hospitals, clinics, and child guidance clinics are utilized and cooperate in the suspected diagnosis and in outlining the treatment. Most cases are diagnosed elsewhere than in the school. However, should the first attack occur in school, a full description is given to the parents for the family physician, specialist or clinic. Only after a thorough study of the history and examination is made, and that from the point of view of excluding all possible known causes for seizures, is a diagnosis of "epilepsy" made. Such diagnostic certitude may take for its realization a matter of several weeks or months. In any event, an attempt is made to confirm the diagnosis by utilizing the services of one or two physicians who have seen the patient in an actual attack.

The diagnosis in certain instances seems to be confusing for a time, especially in the petit mal cases. The differential diagnosis between hysteria, habit spasm, and mental deficiency has to be considered. On occasion, resort to observation in a local hospital over a period of time might be utilized to clinch the diagnosis. Although the statistical data is too meager to be unduly significant, only some twenty-five to fifty per cent were excluded from public school.

4 *Ways of cooperating* included referral of all suspect cases of epilepsy to the family physician, hospital or child guidance clinic, or specialist. At times, winning the parents over to such an examination seemed to be difficult owing to their emotional blindness to admit anything "wrong" with the child. Usually, however, the parents are quite cooperative. Frequently, consultation of the parent with the school physician occurs before seizures take place in school in order that a proper understanding and handling of such exigencies may be in order. The school nurse or public health nurse calls upon the parents to explain the condition of the epileptic child to them and to assist the parents in following through the medical treatment outlined by the family physician, specialist, or clinic. Of particular value is nursing service when the parent refuses to take the child to the family physician or clinic for diagnostic treatment service.

In cases of recommended institutional care, the school physician and nurse are of significant service. One city school reports that the other children in the classroom, teachers, janitors, and principals cooperate in handling the child during attacks and see that he is returned home

safely. Cooperation in carrying out directions concerning special diets is a difficult matter to attain.

5 The school physician does not undertake *medical treatment*. Wherever possible this is referred to the family physician. Cases are followed up in order to see that competent medical care is being given. The school's observation of such children, together with the academic record of achievement are of significant value when reported to the family physician or clinic. The school physician attempts to see the children in at least one typical convulsion although in certain instances the school physician asks to be on call for all seizures. This, however, is not generally regarded favorably since the physician should coach the teacher and pupils toward a sympathetic understanding, acceptance, and handling of the child during an attack and sequelae. The school physician also has periodic conferences with the nurse who reports to him progress made with the child in relation to treatment by family physician and the quality of cooperation of the home. One of the important duties of the school physician is to desensitize the teacher and pupils about unwholesome fears and repugnances which are apt to arise when a child is overtaken with a grand mal attack. Reassurance, calmness, objectivity, and treatment of the child as though nothing were unduly wrong are emphasized. How to make the child comfortable and safe during an attack is explained.

Utilizing a combination of various reputable treatments are invoked, such as luminal, bromides, diet, and a modification of the child's twenty-four hour schedule of living in order that precipitating excitants may be prevented and constructive interests and activities be habitually incorporated in the child's pattern of adjusting to life. The school physician is attentive to the child's general hygienic condition, the elimination of all significant difficulties, and the exercise of attitudes and habits which will assist him in the light of his individual personal, social, and emotional needs. In most instances the explanation to the parents of the nature of the illness is left to the family physician.

6 The *educational treatment* of such children concerns itself with the modification of the curriculum to meet the individual needs of the child. The first prerequisite is to see that the child's condition is adequately interpreted and accepted by the teacher and the other pupils. It

is surprising to note that in certain school systems (two out of nineteen) the curriculum is not modified in any way to assist such children. Where mental retardation as well as epilepsy is present the child is given the advantage of special class treatment, should it be available. In epileptic children of normal mentality, the practice is to retain them in regular classes so that unwholesome discrimination may be avoided. It is interesting to note that one city school, as soon as the diagnosis of epilepsy is made, seeks the advice of a psychiatrist as to the care and amount of educational work the pupil should be undertaking.

The epileptic child is permitted to carry on in a public school just as long as possible without unduly disturbing the school situation. Everything is done in order to retain this type of handicapped child in the regular classes. Both teachers and pupils are encouraged to display sympathetic and helpful attitudes and to regard such pupils in a matter-of-fact way without paying more attention to them than is paid to others. Of course, when fighting is displayed or soiling of clothing becomes an acute problem, special provision should be made, especially where highly strung children in the same classroom become so emotionally upwrought that they are unable to carry on their education in a satisfactory manner. It is remarkable, states one school physician, how seldom complications arise. Even in fairly severe and frequent attacks, the child may go on in school for years and classmates are often made more or less indifferent to the seizures.

Home teaching is provided for those who are too ill to attend school, and who can profit by such instruction. In this connection, the State Department of Education is vitally concerned through its Bureau for Handicapped Children. Epileptic children reported to this Bureau are whenever possible, referred to a mental hygiene clinic, specialist, or hospital for verification of the diagnosis, treatment, and prognosis. After this Bureau receives the report from the physician or clinic concerned, home teaching is arranged, providing the child's mental ability is at a teachable level and the family cooperates with the physician in the specific and general treatment outlined. Of course, guidance is also considered an important matter. A re-examination once a year at the child guidance clinic is sought in order to evaluate the degree of mental deterioration, if any.

This Bureau feels that as soon as a child has a "seizure" he should be excluded from school until the nature of the condition is determined. The upsetting nature of such attacks and the lack of understanding of the teacher and pupils in handling the situation seem to make exclusion desirable. On the other hand, an injustice is done to many epileptics exempted from school if they are allowed to "run wild" about the community without guidance or supervision. Of particular concern is the adolescent epileptic who is frequently side-tracked in gang and delinquency tie-ups. He is apt to become the foil of the gangster, easily enmeshed by the police and thrown into jail.

State aid to epileptics receiving home teaching in New York State is at present about six cases a year. It is regrettable that during the past seven years the degree of success of home teaching has been discouraging. A number of factors enter into this result, chief of which is a hopeless or indifferent attitude which is engendered when the diagnosis of "epilepsy" is made known. In certain instances the general practitioner is thought to be a little indifferent on the one hand, and the parents on the other hand frequently are too emotionally involved to give a satisfactory type of home atmosphere and facilities for care and treatment. From the educational standpoint the home teacher is apt to complain that "he forgets what he is taught."

It is interesting to note that a leading epileptologist in our State urges that epileptic children be kept in public schools as long as it is possible in the light of their educational, social, and vocational opportunities. It is pointed out that many epileptics continue through middle life earning a satisfactory living and doing quite well from the standpoint of citizenship and family formation.

Buffalo is the only city in New York State which maintains a special class for epileptics in the public school. These are included in a class for cripples. The teachers of such children should, of course, have a type of personality which is both understanding, composed, and tactful in meeting the vicissitudes that are apt to arise. Cots are utilized in a special room so that children following a seizure may be adequately taken care of. A special diet for them is supervised by dietitians attached to the general hospital. Teachers and parents cooperate with the hospital in carrying out medical recommendations.

It has come to the attention of the writer that another leader in the treat-

ment of such conditions in our State advocates that the knowledge of seizures be rigidly hidden from the public, and if seizures do not occur in the daytime the child should be retained in regular schools. The teacher as well as the pupil should be made cognizant of the promontory symptoms in order that injuries may be prevented and proper care be instituted the earliest moment. It is interesting to note that one school is very flexible in shaping its program to meet the epileptic child's condition. The hours of school attendance may be shortened, for example, he may not come to school before ten o'clock, or may attend only a half day. The classroom utilized is on the first floor in order to avoid stairs and hazards of falling. Such children are not called upon for recitation unless they volunteer. They are exempted from gymnastic work especially that which involves hazardous situations such as trapeze work and swimming. Rest periods as may be advised by the family physician are carried out in school. When a child changes classes, a conference is often held by the school physician and teachers in order to procure a sensible and helpful attitude on the part of the teachers and children. The school program is modified to fit individual needs when mental deficiency is present (IQ 50-75). The child is given the advantage of special class instruction. There is much leeway given to the epileptic child as is found expedient, especially avoidance with respect to the competitive aspects of work achievement. In view of his tendency to become unduly involved over details, a longer time is required. Thus the child is not pushed, although stimulated in keeping up with his work.

Since the psychiatrist is also concerned with problems of social deviation as well as personality and emotional problems of epileptic children, it is important that he make known to the school physician and the teacher the relationship of these to the nature of the epileptic seizures. Such problems as slowness of grasp, confusion, and poor retention have to be interpreted in the light of his illness particularly in relation to the time of seizure. Although there is a common ground of general plan in the handling of behavior problems of all children, yet the epileptic in view of the dramatic nature of his illness is apt to foster overconcern and oversolicitude which frequently militates against good discipline and need of building up his cautious independence and self-reliance.

It is important that we do not label children with a so-called "epileptic per-

sonality" as it is felt that this causes discouragement and indifference on the part of teachers and others. It is our feeling that there is no clear-cut type of personality which can be attached to the epileptic as peculiar to this illness since individual differences in personality make-up are constitutionally and experientially determined rather than epileptic reaction-type determined.

It is important that the teacher realize that the epileptic of average intelligence may at times simulate the picture of a child with mental retardation because he is unable on occasion to use his intelligence. Such children, however, should not be placed in special classes for the mentally retarded or in a State Institution for the Feeble-minded. If we find the patient is slowing up, is apathetic, or inattentive the teacher should pay more attention to the child through stimulating his interests but under no condition should he be "pushed." With respect to personality deviations such as increased sensitiveness, egotism, self-centeredness, and a tendency to daydreaming, and such behavior difficulties as temper outbursts, it is important that we try to find out *why* the child is so reacting in the light of a number of factors other than the epileptic reaction *per se*. The type of teaching required for the mental defective is quite different from that which is desirable for the epileptic child. In the former we note a lack of capacity to understand and, therefore, emphasize the importance of habit training and routine type of interests and activities which will give him the necessary information, knowledge, and skills. But such monotonous teaching would not do for the epileptic child who needs rather short hours of teaching pressure, a variegated program to keep up his interests, and an emotional atmosphere which prevents undue excitement or discouragement.

Children presenting epileptic fugues or twilight states in which impulsive and antisocial behavior may result, can not safely or profitably be retained in a public school.

7 The chief criteria for recommending institutionalization of epileptic children are poor home conditions with inadequate guidance and supervision, frequent and violent seizures not responding to treatment, intelligence at so low a level as not to be able to profit by public school or home teaching. Only after the community resources are exhausted is the recommendation for institutionalization made.

Each child has to be studied individually

in the light of a number of factors. An often overlooked advantage of institutional care and treatment is the fact that such places often provide superior facilities for the understanding and treatment, both educational as well as medical, of such children. Moreover, in view of the oft-repeated social criticism and even ostracism which leads to marked unhappiness in the case of sensitive personalities, a special school for such children would be a delightful haven of refuge. Recommendation for hospital care or institutional treatment usually comes from the physician of the family.

One school physician reports, "If home care is good, and the child is not too much of a burden so that the other children in the family are neglected, or if antisocial reactions are not displayed, we do not consider suggesting that such a child be sent to an institution." In the case of well-to-do families, epileptic children therein are retained profitably through the utilization of trained teaching and supervisory personnel.

Our statistical data indicates that about twenty per cent of epileptic children become committed during the school age period to institutions for the epileptic (5%) or to State Schools for the Feeble-minded (15%), about fifty to seventy-five per cent are retained in public school, and twenty-five to thirty-three per cent are excluded from public school and live at home.

Summary and Conclusions

The facts of the understanding and treatment of the epileptic school child were obtained from a questionnaire sent to nineteen school physicians of representative cities and villages in New York State. The digestion of this material lends significance to the following topics.

1 Although the incidence of epileptic seizures in school children are relatively small (seven per 10,000 or 07%), yet from the standpoint of school management this type of child presents a most serious type of problem. There seems to be some indication of a diminution in the number of epileptic school children during the past five years. This may point to a better understanding and handling of the contributory factors making for or against convulsive states, such as cranial birth injuries, lues, encephalitis, dietary indiscretions, foci of in-

This Bureau feels that as soon as a child has a "seizure" he should be excluded from school until the nature of the condition is determined. ORBITAL INFECTIONS DUE TO NASAL SINUSITIS

A Study of 114 Cases

LOUIS HUBERT, M D, *New York City*
Junior Surgeon, Manhattan Eye, Ear and Throat Hospital

Because of the limited time at my disposal, I will analyze very briefly 114 cases of orbital infections due to nasal sinusitis, which were admitted to the Manhattan Eye, Ear and Throat Hospital during the last ten years. At the start let us consider how infections of the nasal sinuses may extend into the orbits. They may do this in two ways, namely (1) by direct extension from the diseased bony walls, which separate these sinuses from the orbital cavities, and (2) by the venous blood stream, i.e., by a phlebitis of the veins of the various sinuses, which anastomose with the superior and inferior ophthalmic veins that supply the fatty cellular tissue of the orbits.

The venous supply of the various sinuses is shown in Fig 1. It can readily be seen how a phlebitis of one of these veins may extend into the superior or inferior ophthalmic veins, which communicate with the cavernous sinus.

The area that contains the cellulofatty tissue of the orbit is shown in Fig 2. In this space are also found the extrinsic ocular muscles, the optic nerve, and the superior and inferior ophthalmic veins. Lymphatics are entirely absent in this area. It is limited by a rather thick membrane, called the orbital fascia, which is a part of the periorbita or periosteum lining the bony orbit, and can be easily separated from its bony attachment. When so separated it is frequently misnamed by rhinologists, Tenon's capsule. The anterior surface of the latter, as is shown in Fig 2 is in intimate contact with the eyeball, and its posterior surface is closely related to that part of the orbital fat that surrounds the eyeball. The orbital fascia, however, supports the orbital contents in relation to the bony orbital walls.

Classification of Orbital Infections

All orbital infections can be classified in the following five groups

1 Inflammatory edema of the eyelids with or without edema of the orbit.

2 Subperiosteal abscess, (a) with edema of the lids and orbit, (b) spreading of the pus to the lids (erroneously called orbital abscesses)

3 Orbital abscess

4 Orbital cellulitis, (a) severe, (b) mild.

5 Cavernous sinus thrombosis, (a) septic, (b) aseptic(?)

In the first group the infection is confined to the nasal sinuses, and there is only an inflammatory edema of the lids, which may become markedly swollen. However, the eyeball is movable in all directions and the vision is usually not affected. In this stage the orbit proper is not involved. The edema may, however, extend into the orbital tissue. When this occurs there appears a slight exophthalmos and some limitation of movement of the eyeball. These patients usually get well within a week or ten days under conservative treatment. At times this edema may be the beginning of the more severe orbital infections. It may also accompany a fulminant sinusitis in which the infection has spread to the meninges or brain, but these patients are very ill and show signs of intracranial invasion.

Thirty-one patients belonging to the first group were admitted to the hospital as bed patients. Of these, twenty were successfully treated symptomatically. One had a lid incised, but no pus was found. One had the middle turbinate removed. Nine had external radical operations. There were five deaths in this group. One died of meningitis following the external operation and four died of brain

fection, early diagnosis and treatment (medical, psychological, educational, and environmental)

2 The chief criteria for exclusion and exemption from school are severe and frequent seizures, inability of the child to profit by regular school attendance because of low mentality, or behavior problems so upsetting that retention in school becomes impossible. There is a tendency to exclude every child with a seizure until adequate diagnosis can be made. The fact that only twenty-five to fifty per cent of epileptics are excluded from public school indicates the value of intelligent understanding and the shaping of school attitudes and facilities to serve the needs of this type of handicapped child. A more hopeful outlook for happily and effectively retaining him in the community from the standpoint of social-educational growth is now entertained than formerly. Nevertheless, a long term comparative study of the relative advantages and results of early institutionalization versus home-school-community adjustment is needed.*

3 The diagnostic criteria for epilepsy are periods of loss of consciousness, jerking movements, frothing at the mouth, and other features of the grand mal type. The vacant stare of "absences" of petit mal followed by amnesia for the attack are characteristic. Differentiation of epilepsy from hysteria, mental retardation, and organic conditions such as central nervous system lesions, brain tumor, post-traumatic injuries, and postencephalitic conditions must be considered.

4 Cooperation of the school physician, public health nurse, family physician, parents, hospital and child guidance clinic, as well as psychiatrist or neurologist, is necessary in order that continued care and supervision of the child may be adequate.

5 The school is not concerned with treatment, and usually diagnosis is re-

ferred to the family physician who confirms this by consultation with specialist, hospital, clinic, or other physician.

6 The educational treatment in the case of the epileptic child of average intelligence is to retain him in the normal age-grade grouping by individualizing his program as much as may be indicated. Of particular moment is the sympathetic and helpful understanding and handling of the child by the teacher and pupils. Home teaching is arranged for those who have too many or too-severe seizures to permit attendance at public school, and who have the intelligence (at least 60 IQ) to profit by such instruction. Allowance must be made for learning process difficulties such as inattention, confusion, and entanglement of details in order that he may not be further confused and excited, since this may give rise to seizures. He must not be classed with the child who is mentally retarded, although a combination of this and epilepsy is quite common.

7 The tendency is to retain the child in a public school or in the community with home teaching as long as is possible. Indications for institutionalization are frequent and severe seizures, inadequate home treatment, guidance, or supervision, and the superior advantages (medical and educational) of institutions caring for epileptics over those agencies in the local community.

8 Comments are made as to the understanding and treatment of the child, particularly with respect to the educational angle as it touches upon the work of the school physician in the light of home-school-community relationships.

* Fox² reporting on a study of 351 epileptic children cared for and passed through residential special schools over an eight year period states that of every fourteen such children, four (29%) are more or less self-supporting, two (15%) are at home without gainful employment, five (36%) are in institutions; and two (15%) are dead.

certain in cases of a unilateral sinusitis and orbital cellulitis in which the orbit on the side of the noninfected sinuses has become involved. The difficulty in the clinical diagnosis is due to the fact that the signs which are supposed to be characteristic of it and are attributed to it, are not due to a thrombosis of the cavernous sinus *per se*, but to a phlebitis of the ophthalmic veins. Even a positive blood culture may be present in a case of orbital cellulitis without cavernous sinus thrombosis. It is therefore impossible to say how many of the six cases of orbital cellulitis that died of meningitis also had an accompanying cavernous sinus thrombosis.

In the fifth group there were two cases of septic cavernous sinus thrombosis. Both died. Two cases that recovered were diagnosed as aseptic cavernous sinus thrombosis. This diagnosis is of course doubtful. To illustrate this condition, one of the cases will be briefly reported.

CASE 1 A man, thirty-eight years old, was admitted to the hospital on March 2, 1932. Three weeks before admission he had a cold in his head and was confined to bed for five days. A week before admission the left eye began to be painful and swollen. On admission the left eye was tremendously ptosed, the upper and lower lids markedly edematous, and the conjunctiva extremely chemotic. The right eye showed a slight chemosis of the upper lid. On March 9, a radical external operation on the sinuses was done on the left side, also a Kronlein operation to investigate and to decompress the left orbit. No pathology was found on gross examination. The patient was discharged on April 14, very much improved. Within a few months the entire condition cleared up.

Involvement of Nasal Sinuses

In ninety cases the sinuses involved could be determined by clinical examination, x-ray studies, and operative findings. In thirty the frontal sinus was involved, in twenty-two the frontal and ethmoidal sinuses, in twenty-six the ethmoids, in five the ethmoids and antrum, in two the antrum, in one the ethmoids and sphenoid, and in four cases all sinuses were involved. In twenty-four cases the sinuses involved could not be determined with certainty.

Age

The youngest patient was two months old and the oldest seventy-eight years. Twenty-four cases were in children between the ages of one to ten years.

Treatment

The surgical and medical treatment that these patients received was not uniform. It depended a good deal on the different viewpoints of the various rhinologists who took care of them. The

Fig 2 Orbital contents and arrangement of the Capsule of Tenon. (After F Treves)

plan of treatment here recommended is the one used at the Manhattan Eye, Ear and Throat Hospital, clinic of Dr Francis White.

In the first group of cases, nonoperative treatment is advised. Occasionally in cases of acute fulminant sinusitis with orbital edema, high fever, and severe pain, the surgeon may be tempted to do an external operation on the sinuses. The results, however, have usually been unfortunate. If the sphenoid is involved it should, of course, be washed out and drained.

In the second group, where a subperiosteal abscess is present, the usual curvilinear incision for the external ethmoid operation is made, the periosteum separated, the bony orbit examined, and the pus evacuated. This maneuver does not only evacuate the pus but makes a definite diagnosis of the sinus involved.

abscesses that accompanied the orbital edema. Many more cases belonging to the first group were treated in the clinic, but are not included in this study.

In the second group the infection involves the bony wall and the periosteum and a collection of pus forms between them. There is a circumscribed swelling, which is painful to the touch. The eyeball is displaced and its mobility interfered with, depending upon the location of the subperiosteal abscess. The

Fig 1 Diagrammatic representation of afferent and efferent venous channels of the cavernous blood sinus (After Turner and Reynolds)

pus may extend into the lids and break through, forming a fistula. These cases are frequently misnamed orbital abscesses. There were forty-six cases that belonged to the second group. In nine of these the pus was confined between the bone and the periosteum and in thirty-seven the pus involved the lids. All recovered after surgical treatment, which will be discussed shortly.

In the third group the infection spreads into the orbital tissue proper either through the orbital wall and fascia or through the venous circulation. There is a very pronounced exophthalmos, an extreme chemosis of the conjunctiva, an immobility of the eyeball,

and interference with vision. The pus may spread to the lid or the conjunctiva and break through. When this does not occur, and it frequently does not, it is impossible to distinguish clinically an orbital abscess from an orbital cellulitis. The diagnosis is then made at the time of the operation. There were twenty-two cases of orbital abscesses. Two of these died of meningitis and one of a brain abscess.

In the fourth group the infection extends into the orbital tissues through the venous circulation, causing a phlebitis of the ophthalmic veins. These patients are extremely ill, have a very high temperature, 105 to 106° F, an extreme exophthalmos and chemosis of the conjunctiva, a fixation of the bulb, and disturbance of vision. Macroscopically there is no evidence of pus at the time of the operation, but microscopically there are found small areas of purulent inflammation and necrosis scattered in various places of the retrobulbar tissue, especially in the vicinity of the veins, also evidence of periphlebitis and phlebitis. There were nine cases of severe orbital cellulitis, six of which died of meningitis.

Quite frequently patients are seen, especially in the eye clinics of the hospital, that present a picture of a mild orbital cellulitis following a nasal infection. They do not appear very sick and are treated in the clinic. Two of them were admitted to the hospital and discharged cured after a few days of local treatment. These patients also present an exophthalmos, a chemosis of the conjunctiva, an immobility of the eyeball, but instead of getting worse as the cases with severe orbital cellulitis do, they improve daily, showing that the infection is mild and can be taken care of by the natural defenses of the body.

In the fifth group the infection has extended from the ophthalmic veins or directly from the sphenoid sinus into the cavernous sinus. These patients present a picture of a severe orbital cellulitis. It is almost impossible to distinguish clinically such an orbital cellulitis from a cavernous sinus thrombosis, unless it is accompanied by an edema over the mastoid emissary. The diagnosis is also

In the fifth group, the treatment should be preventive. I doubt very much if anything can be done when we are confronted with an acute fulminating cavernous sinus thrombosis. However, inasmuch as the diagnosis is usually difficult to make, it is advisable to treat these cases the same way as those suffering from severe orbital cellulitis, in the hope

that the trouble is still confined to the orbital tissues.

It is my firm belief that if the plan of treatment outlined in this paper is carried out, the number of cases of meningitis resulting from nasal sinusitis and orbital infections would be materially reduced.

Discussion

DR. FRANK C. KEIL, *New York City*—Dr. Hubert has left very little to discuss in his excellent study of 114 cases of orbital infections due to nasal sinusitis. There are a few points in diagnosis and treatment which deserve special attention.

1. Differential diagnosis.
2. Fundus examination.
3. Some points in operative treatment to be emphasized.

Although various observers have found that over fifty per cent of orbital infections are secondary to sinus disease, it is well to remember other etiological factors and that a coexisting sinus infection might not be the causative factor. Although serological and x-ray examinations along with local signs in the nose will aid in eliminating tuberculous, leucic, and neoplastic conditions in the orbit, other conditions must be eliminated. The spread of infections from neighboring parts such as an acute dacryoadenitis, acute dacryocystitis, hordeolum, and a panophthalmia must be considered. Infected wounds of the face, erysipelas, infections secondary to septic pharyngitis, abscessed teeth, and metastatic infections from a septicemia or a septic venous thrombosis in the extremities should be noted. The latter conditions might also be responsible for a tenonitis which must be differentiated.

Exophthalmus, redness, and swelling of the lid in a bottle-fed infant from four to nine months of age should arouse a suspicion of infantile scurvy. Cases have been reported of subperiosteal orbital hemorrhages in scorbutic infants who have been operated upon for orbital abscesses. A temperature of 102° or 103° F frequently found in infantile scurvy is often very misleading.

Edema and redness of the lid, a frequent sign of an acute sinusitis must not be confused with an exophthalmos. The former does not indicate orbital involvement. The positive signs of orbital involvement are chemosis of the conjunctiva, exophthalmos or ptosis of the globe, along with loss of mobility. Subjective symptoms of pain

in the eyeball and orbit or pain on moving the eyeball, blurring of vision, and tenderness of the globe on pressure frequently present, might be absent. It is also possible for an orbital infection of nasal origin to occur with negative nasal findings. The original nasal infection might have cleared before the orbital signs became manifest.

The fundus signs are frequently conspicuous by their absence. The edema of the corneal epithelium usually present renders an ophthalmoscopic examination exceedingly difficult and unsatisfactory.

With thrombosis of the ophthalmic veins or central vein of the retina often found associated with cellulitis of the orbit and cavernous sinus thrombosis extensive retinal hemorrhages, optic neuritis, papilledema and venous engorgement are noted early in the disease.

Dr. Hubert has given a very concise pathological classification of orbital infections. It is frequently impossible to assign a case to one of a group as the conditions frequently overlap. It is only after the incision has been made that the case can be properly classified.

As to treatment conservative measures might be followed a longer time with adults than with children. The small size of the parts concerned in the latter might lead to immediate extension of the infection to the meninges and other complications.

The old treatment of a puncture with a cataract knife through the conjunctiva into the orbit has been condemned for some time. This procedure gave no drainage and only scattered the infection throughout the non-infected orbital fat. Unfortunately one can find this treatment recommended in some of the not-so-old textbooks in ophthalmology.

The curvilinear incision is the accepted incision. If pus is not found on separating the periosteum incisions should be made through the fascia into the cone of ocular muscles. Until this has been done, one cannot be sure that an abscess within the muscle cone has not been overlooked.

DR. FRANCIS W. WHITE, *New York City*—The comprehensive paper of Dr. Hubert

After the subsidence of the acute symptoms, a radical operation on the involved sinuses is done. In two of the cases this was unnecessary, as there probably was only a mild involvement of the bony orbit, with little bone destruction.

In the third group, the orbital wall and orbital fascia are exposed as in the second group. If both are intact an incision is made into the orbital fascia and if an abscess is present, pus will escape. In these cases the infection has extended into the orbital tissue by the venous circulation leaving the bony wall and periosteum uninvolved. No radical operation on the sinuses is necessary in such cases. A few rubber drainage tubes are passed through the incised orbital fascia into the retrobulbar tissue, where the abscess is, and allowed to come out through another incision made in the lower lid. To illustrate these points the following case is briefly reported.

CASE 2 A two months old baby was admitted to the hospital on October 26, 1936. A week previous to admission the child had a nasal cold. Then the right eye became enormously swollen. On admission the right eye was ptosed, and the chemosis of the conjunctiva was so marked that the cornea could scarcely be seen. There was complete fixation of the eyeball. After making the usual curvilinear incision, I exposed the orbital plate and fascia, which appeared normal, indicating that the infection had travelled through the veins. The orbital fascia was incised and a large amount of pus exuded. The orbital plate was not removed, and no operation on the sinuses was done. The recovery was uneventful.

There were ten other cases of orbital abscesses in this series, which recovered after drainage without radical operations on the sinuses. However, if the bony orbital wall is diseased, a radical operation on the nasal sinuses is essential. It is recommended to do this after the subsidence of the acute symptoms. In eleven cases of orbital abscesses, a radical operation on the sinuses was necessary. The importance of investigating the orbital contents is shown by the following case.

CASE 3 A girl, eight years old, was admitted to the hospital on July 28, 1935.

The left eyeball was ptosed, immobile, and the chemosis of the conjunctiva was so marked that the cornea could not be seen. On July 29, the usual external radical operation on the sinuses was performed by one of the assistant surgeons of the hospital. The next day the condition of the child was worse. It seemed that the eye would be lost because of the increasing proptosis and chemosis. The temperature was very high and there were signs of meningeal irritation. The child was re-operated and a large collection of pus was found in the retrobulbar tissue. On August 17 the patient was discharged cured.

The fourth group gives us the greatest amount of trouble. In these cases there is no visible pus present in the orbital contents. As the infection has travelled through the venous circulation the orbital bony wall may be intact. The orbital fascia, although not involved, is under extreme tension. Incising the orbital fascia is not sufficient. A radical operation on the sinuses must be done to decompress the orbital contents, to relieve the pressure on the optic nerve, and to prevent the extension of the infection to the cavernous sinus and to the meninges. A radical operation on the sinuses alone, as is usually done, without drainage of the orbital contents, results often in fatalities. For the purpose of illustration the following case is briefly reported.

CASE 4 A man, thirty-five years old, was admitted to the hospital on June 14, 1935. He had an extreme proptosis and fixation of the right eyeball, marked chemosis of the conjunctiva, and excruciating pain. The vision was reduced to light perception in that eye, with a choking of the disk of three diopters. It appeared to be a case of cavernous sinus thrombosis. He was operated upon by me on June 19. The orbital plate, when exposed, appeared normal. The orbital fascia was intact, but very tense. When incised, the orbital fat came out under pressure, but no pus was present. The orbital bony wall was then completely removed, including the floor of the frontal sinus. There was no pus present in any of the sinuses. Three rubber tubes were inserted into the orbital contents through the incised fascia. When the patient regained consciousness the first thing he noted was the complete relief from pain. He was discharged cured on July 28, with 20/70 vision in the affected eye.

THE POLYCYSTIC KIDNEY

With Special Reference to Complications and Treatment

JOSEPH A. LAZARUS, M.D., *New York City*

A brief summary of the outstanding features of the polycystic renal disease would help to explain the underlying causes of some of the complications occasionally encountered in this disease.

Polycystic disease of the kidney is characterized by the formation of cysts within the renal parenchyma due to congenital occlusion of portions of the renal tubular system. Kidneys so involved have been known to grow to enormous size. Although the pathological process is most apparent in the kidney, cystic changes have been noted in other organs, such as the liver, ovary, uterus, bladder, and epididymis. Although one occasionally reads of a case of so-called unilateral polycystic kidney, it can be stated as a rule that polycystic disease involves both kidneys, either equally or one more than the other. Removal of one polycystic kidney under the assumption that its mate is normal will, within a few months after operation, disclose the typical pyelographic deformity characteristic of this disease in the remaining kidney. Occasionally, a kidney, the seat of a group of multilocular cysts due to acquired occlusion of renal tubules and having nothing at all in common with polycystic disease clinically or embryologically, will be mistaken for a polycystic kidney, leading to the erroneous assumption that the condition is one of unilateral polycystic kidney.

Polycystic disease is frequently encountered in several members of the same family, thus lending additional evidence to the congenital nature of this entity. Yet, in spite of the fact that this disease is congenital, symptoms rarely appear before the fourth decade, the greatest incidence occurring between the ages of fifty and sixty, with both sexes equally affected.

About thirty per cent of patients with polycystic disease succumb within two years after the onset of symptoms, about fifteen per cent live between two and four years, while the remainder (55 per cent) have been known to live five to twenty

years after the diagnosis has been established. Fifty years appears to be the average age at the time of death. The amount of destruction of renal parenchyma by pressure of the cysts upon renal substance, either due to atrophy or resulting from a superimposed complication, seems to be the predominating factor influencing the span of life in these patients.

Whether the onset of symptoms be acute or insidious, death as a rule results most frequently from uremia or from a vascular accident. Pain, which may be dull or colicky in character and usually localized to one side, constitutes a not infrequent symptom. At times the pain is so severe that it simulates an attack of renal colic due to the passage of a ureteral calculus, and is usually due to the passage of small blood clots or, as occurred in the case about to be described, to the pressure of a cyst upon the ureter. Chills, fever, and dysuria are symptoms which denote a superimposed renal infection. Hematuria is a frequent symptom, and when bleeding occurs from one kidney particularly in the presence of pyelographic distortion of that kidney with only incipient changes in its mate, one is extremely apt to look upon the lesion as a true renal neoplasm. Depending upon the degree of parenchymal destruction and its consequent blood nitrogenous retention, one obtains a history of nausea, vomiting, asthenia, and loss of weight.

Physical examination usually reveals the presence of an enlarged kidney on one or both sides, and in cases with unusual enlargement of the left kidney, one may note the presence of a varicocele. Elevation of blood pressure is rarely lacking, and when accompanied by fixation of specific gravity of the urine with or without a trace of albumin, is extremely suspicious of polycystic disease. An interesting feature in the early stages of the disease is a delay in the appearance of the dye, although there is no decrease in the total two hour 'phthlein output.

on orbital infections leaves but little for discussion. Dr Keil has very carefully elaborated upon the ophthalmological aspects of orbital infections caused by or only incidentally associated with acute suppurative sinusitis. Therefore, it devolves upon me only to stress some of the points concerning classification and treatment that an analysis of the 114 case reports revealed, plus the knowledge gained by the application of these deductions.

Those of us, however, who have been observing, having noted a lessening of the very radical sinus surgery, and the beginning of a more conservative surgery are no doubt in accord that the latter is the logical method of treatment. Not alone is the improvement in procedure due to a change in the attitude of the rhinologist, but rather to the teamwork of the rhinologist, ophthalmologist, and roentgenologist. The latter, particularly, is a most important ally.

You will find the classification of acute sinus diseases, as given here, of the greatest help. The treatment is predicated upon results that cannot be doubted. Probably, the type most frequently complicated by surgery is the first, namely, edema of the eyelids and orbit. Too great haste in operating only prolongs a condition that under conservative treatment would recover. The second type, subperiosteal ab-

cess, is self-explanatory, and the treatment is logical. It is in the third type, or orbital abscess, that grave consequences may arise if the surgeon does not seek pus by boldly incising the orbital fascia and employ two of the surgical triad of pioneer surgeons, which was, "open, disinfect, and drain." We do not resort to disinfection, however, as heretofore. In the fourth type, namely, orbital cellulitis, although the condition may clear up under conservative treatment, still, if no improvement is seen or the reverse occurs, then open and drain by incising the orbital fascia. Do not be disappointed if macroscopic evidence of pus is lacking—it is there, and free drainage is your best friend. By removing the adjacent bony wall, a decompression of the orbit is obtained. By successfully treating types 3 and 4, type 5—namely, cavernous sinus thrombosis, may be prevented—which is the best form of treatment.

In concluding, may I suggest that you look upon acute suppurative involvements of the nasal accessory sinuses as being somewhat similar to pyogenic conditions in the soft tissues of the body. The indications would then be early free drainage of the accumulating pus and with the recession of the acute symptoms a radical removal of all diseased tissue.

DOCTORS BLAMED FOR INJURED ATHLETES

Physicians engaged in the examination of school children should be interested in the proposal to place the control of interscholastic athletics under the State Board of Regents—to better safeguard the health of the student athletes, observes the *Onondaga Medical Society Bulletin*.

In an address before the American Physical Education Association at Hotel Pennsylvania, in New York, F. R. Wagner, secretary of the New York State Public High School Athletic Association, held physician and coaches responsible for the numerous injuries to football players in permitting them to enter games with past records of fractures and other physical defects. He said:

"While at the present time it is generally conceded that boards of education

in the state are not directly responsible for injuries to boys engaged in athletics, I believe this is partly due to the fact that no one has seen fit to press certain types of cases legally.

"If a lawyer could show that a coach was negligent in placing some partially injured boy in a football game, the parent could prove a clear case against an agent of the board (the doctor or coach or both) and thus against the board itself."

Mr. Wegner said the large number of injuries to high school football players could be avoided by systematic physical examinations and rejection of those unfit to participate, "instead of the present haphazard methods so often used by high school doctors."

The Doctor was visiting Rastus' wife to deliver her twelfth offspring. While riding along with Rastus he saw a duck in the road.

Doctor "What kind of a duck is that?"
Rastus "That ain't no duck. Dass de stork wid 'is legs wore off."

—Exchange

ney is not hopelessly destroyed. In the latter event, providing the other kidney has previously been found sufficiently competent to sustain life, nephrectomy should be carried out.

3 Hemorrhage

Although hematuria is not an infrequent symptom of polycystic disease of the kidneys and can easily be controlled by rest and pelvic lavage with strong silver nitrate, at times hemorrhage from such a kidney may be sufficiently severe to require prompt radical measures for its control. In other cases, however, hemorrhage may be entirely confined to one or more large cysts not communicating with the pelvis, in which event there is no hematuria, instead the patient complains of severe lumbar pain and presents the typical picture of shock. Attacks of renal colic due to the passage of clots through the ureter are not infrequent in the presence of hemorrhage. The treatment of cases of severe bleeding consists in performing Rovsing's multiple punctures of the cysts.

4 Attacks of Renal Colic Due to Occlusion of the Ureter by an Adjacent Cyst

To illustrate such a possibility, the following interesting case is presented.

A man, forty-three years of age, presented himself with a history of attacks of left renal colic of eight years' duration. Two months previously he passed a small calculus. Save for several attacks of hematuria there were no other symptoms.

Physical examination revealed a large, hard, irregularly shaped, movable mass in the left loin which was considered to be the left kidney. The right kidney could not be palpated. Blood pressure 156/100. *Urinalysis* Faint trace of albumin with several RBCs and an occasional leukocyte. Specific gravity 1.012.

Cystoscopic examination failed to reveal an obstruction in either ureter. Urine from the right kidney was negative, while that from the left contained numerous red blood cells. Phthalein given intravenously appeared in good concentration from the right side in three minutes and from the left in four minutes.

The shadowgraph film showed the right kidney of normal size, shape, and position, with the tip of the catheter lying in the renal pelvis. The left renal shadow was markedly enlarged and presented a stag-

horn shadow in the region of the lower calyx. The upper third of the catheter made a complete outward arc. A retrograde left pyelogram showed the pelvis rotated anteriorly and the calices broadened and clubbed. The intravenous pyelograms confirmed the findings of the retrograde pyelogram of the left kidney, and revealed the right pelvis normal (Fig 1). A nega-

Fig 3 Pyelogram of right kidney four months after nephrectomy. Note large cyst pressing on ureter, causing attack of renal colic.

Fig 4 Right shadowgraphy of kidney after evacuation of cyst.

Fig 1 Pyelogram of right kidney prior to left nephrectomy

Fig 2 Surface view of left kidney following extirpation. Note large cyst pressing upon ureter

Roentgenologically one can usually discern enlargement of the renal silhouette and on good films it is also, at times, possible to actually visualize the projections of the individual cysts beyond the

limits of the renal cortex. However, it is by means of pyelographic studies that the diagnosis is usually confirmed, the outstanding features of the pyelogram being elongation, bowing, and broadening of the calices. Occasionally the calices may be shortened or entirely obliterated

Complications and Their Treatment

Just as happens in other types of anomalous kidneys, polycystic kidneys are more prone to complications than are normally formed kidneys. It is the writer's belief that the chief underlying predisposing causes of complications are, *first*, an interference with natural drainage due to pressure of cysts, and *second*, an increase in tension within the cysts which exposes the intrarenal vessels to the danger of laceration

1 Calculi

Calculi situated in the renal pelvis or ureter are extremely hazardous in the presence of polycystic disease due to their ability to hasten the destruction of secreting parenchyma by interference with drainage. Only in rare instances of small nonimpacted ureteral calculi is it advisable to employ cystoscopic catheter manipulation to aid in the expulsion of the calculus. In such cases, however, this procedure must be promptly abandoned at the first indication of infection. The procedure of choice in such cases is pyelotomy or ureterolithotomy supplemented by the evacuation of the contents of the renal cysts by multiple punctures

2 Infection

While in normally developed kidneys the vast majority of infections occur as pyelitis or pyelonephritis, we find in polycystic kidneys infections more frequently resulting in infected hydronephrosis or in pyonephrosis, and this difference is due to the marked incidence of obstruction by cysts in polycystic disease. Owing to the difficulty encountered in introducing a large ureteral catheter into the pelvis of an infected polycystic kidney, the treatment of such cases is usually surgical. Nephrostomy combined with Rovsing's multiple punctures of the larger cysts and decapsulation constitutes the procedure of choice in cases where the kid-

a congenital anomaly involving both kidneys, in which renal destruction results from pressure of the distended cysts upon the renal parenchyma

2 Calculi, infection, hemorrhage, ureteral colic due to compression of ureter by cysts, severe lumbar pain, and impending uremia constitute a group of complications of sufficient gravity to warrant prompt treatment.

3 Owing to the nature of the underlying pathology, the treatment of such complications is usually surgical. The outstanding features in such treatment consist in the evacuation of the large cysts with or without nephrotomy depending upon the presence or absence of infection. Nephrectomy is indicated only in cases where the offending kidney is hopelessly destroyed and the other kidney is capable of sustaining life. Decapsulation is a valuable adjuvant to cyst evacuation.

4 The conservative management of ureteral calculi in these cases is fraught with great danger and should only be employed in cases showing no evidence of

infection, and where the calculi are sufficiently small and smooth to offer a fair chance that they may be expelled after a few manipulative treatments. In doubtful cases it is far safer to perform ureterolithotomy.

5 The author has found the use of short-wave diathermy of great aid in treatment of cases of severe lumbar pain due to a complicating perinephritis.

6 Free and thorough exposure of the kidney is essential in order to expose all cysts, and the use of the electric cutting current passed through a bistoury electrode, using preferably a spark gap machine, in evacuating cysts causes much less bleeding than does the use of the scalpel.

7 Removal of one polycystic kidney promptly brings out the inherent defects in its supposedly uninvolved mate, proving the fact that polycystic disease involves both kidneys.

8 Save for the management of complications, the treatment of polycystic disease is primarily medical.

875 PARK AVE.

NEW YORK TO LEAD IN MEDICAL EDUCATION

Definite progress in a plan which should place New York City in the forefront of all centers of medical education was marked on May 10, when the cornerstone of the Kips Bay-Yorkville Health and Teaching Center building at 411 E 69th St. was laid.

In announcing the ceremonies, Mayor LaGuardia revealed that Health Commissioner John L. Rice has completed negotiations with five of New York's medical schools for the world's largest program in the training of medical students in preventive medicine and public health administration.

The program involves the joint use by the Department of Health and the medical schools of five new health center buildings costing \$1,599,580 on a co-operative basis "which will insure unprecedented training facilities for medical students, nurses and other public health workers."

Two other centers under construction are the Washington Heights Center at West 168th St. and Broadway, and the Lower East Side Center at 21st St. and First Av. The remaining two, on which work will start soon, are the East Harlem Center, on East 115th St. and the Red Hook-Gowanus Center, on Baltic St., in Brooklyn.

The five new teaching centers are part of Commr Rice's district health center program which envisions the erection of thirty district health centers throughout the city.

In announcing details of the plan by which the Department of Health and the five medical schools will interchange services and facilities, Mayor LaGuardia said:

"This program means the enlargement of public health teaching facilities for five of New York City's medical schools. The result will be that these schools will be able to make available the most comprehensive educational program in preventive medicine and public health practice in the world.

"It is my hope that these new facilities will make possible the training of enough men and women in public health administration not only to supply leadership for this great city, but also for others which may need it."

Commissioner Rice, in a report to the Mayor, said the program should place New York City in the forefront of all centers of medical education and described it as the product of the best thought of leaders in the fields of medicine and public health administration.

tive shadow could be made out in the lower pole of the left kidney which occupied the position of the staghorn shadow in the flat film. Extending from the lower pole of the kidney there was an ovoid shadow the size of a tangerine, the lower edge of which reached below the crest of the ileum. A second, large, globular shadow was noted in the region of the upper pole of that kidney.

Operation revealed an enormously enlarged, completely destroyed left polycystic kidney (Fig 2) extending from the diaphragm down into the pelvis. The kidney was removed, and when opened disclosed a large coral calculus in the renal pelvis.

On the fortieth day after the operation, intravenous pyelography disclosed marked enlargement of the right kidney with the typical deformity of the calices characteristic of polycystic kidney.

Fifteen months later he returned complaining of an attack of right renal colic of two days' duration, and accompanied by fever and vomiting, but no chills. There was complete anuria during the past twenty-four hours.

Examination revealed the abdomen distended. Temperature 100.8° F. Upon introducing the cystoscope into the bladder no urine was obtained. The right kidney was easily catheterized and twenty ounces of urine were obtained from that kidney after 1½ hours' drainage. Phthalein given intravenously returned from the kidney in fair concentration after 3½ minutes and in good concentration after six minutes.

Right shadowgraphy revealed the tip of the catheter lying in the region of the renal pelvis, there was no visible shadow of calculus along the ureter course, but the catheter appeared superimposed over the vertebral column, evidently due to pressure by the kidney. Intravenous pyelographic studies disclosed an enormously enlarged kidney with a clearly defined large cyst arising from the lower pole of the kidney and pressing upon the ureter (Fig 3). The first appearance of the dye in the renal pelvis was noted on the twenty-five minute film, and the pyelogram revealed the characteristic deformity of polycystic disease. No dye was noted in the ureter or bladder at any time during this series of x-rays.

At operation the kidney, after being freely exposed, was found enormously enlarged and polycystic, disclosing an extremely large cyst in the mesal aspect of the lower pole of the kidney which completely dislocated the pelvis and upper portion of the ureter mesally. There were in addition many large cysts situated over the body of the kidney and upper pole. The cysts were

evacuated with the electric cutting current, following which the kidney was decapsulated and nephrotomy performed.

Convalescence was uneventful and the patient was discharged on the fourteenth day after operation. There was no recurrence of attacks (Fig 4).

5 Severe Lumbar Pain

Severe lumbar pain may be due, in addition to calculi and hemorrhage, to pressure from an enormously enlarged kidney or from a superimposed perinephritic inflammation. In the latter event the writer has found short-wave diathermy of great value and believes that this procedure should be tried for a reasonable period before instituting surgical intervention. Surgery is indicated in cases where pain is due to pressure and depending upon the degree of parenchymal destruction, nephrectomy being reserved for the hopelessly compromised kidneys, and Rovsing punctures as the procedure of choice in all other cases.

6 Impending Uremia

Since destruction of renal parenchyma in polycystic disease is due to atrophy resulting from pressure of large cysts, one may occasionally retard this process by evacuating the cysts in both kidneys.

Method of Performing Cyst Evacuation

While the scalpel has been the instrument most frequently employed in incising cysts, the writer has found the use of the electric cutting current passed through a bistoury electrode, using preferably a spark gap machine, much more advantageous, since it causes infinitely less bleeding than when using the knife. The operation is best performed under spinal anesthesia. Before evacuating the cysts, the kidney should be freely mobilized in order to visualize both poles and the anterior and posterior surfaces, and the kidney thoroughly packed off from the renal fossa. Following the evacuation of as many of the cysts as can be visualized, it is advisable to thoroughly decapsulate the kidney and drain the perirenal space.

Summary and Conclusions

- 1 Polycystic disease of the kidney is

held his head forward, one had bow legs, and one child held his right shoulder higher than the left.

Twice weekly, exercises based on the some standard series we had worked out for my office were given by Mrs. Just. Usually it was feasible to conduct the exercise with groups of children having the same postural defects. All were children of working mothers, and it was impossible to obtain adequate cooperation at home, so the other three days of the week the children were at the nursery school, they were given the exercises by the kindergarten and the nursery school

teacher, who were kind enough to cooperate. The older school children were supposed to do the exercises at home. Their attendance at the exercise class was the worst, and the results with them the poorest.

All the children were examined by the pediatricist weekly, and their posture especially observed and noted. At the end of five months, a study was made of the entire experience, and Table I is an analysis of the results. Corresponding figures obtained in the private practice group of the children are placed along side for comparison.

CORRECTIVE SUPERVISED EXERCISES FOR POSTURAL DEFECTS

EDWARD T. WILKES, M.D. and ELIZABETH JUST, *Long Island City*

From the Department of Pediatrics, New York Post Graduate Medical School and Hospital of Columbia University Dr. Adolph DeSanctis, Director

About two years ago the disappointment at the results I obtained in my patients with defective posture became acute. After diagnosing the deformity, I had followed the usual procedure in a pediatricist's office, that is, I had given the mother some corrective exercises to do with the child, perhaps demonstrated two or more of them myself in the office, and prescribed appropriate wedging of shoes when necessary. Possibly the mother or nurse did the exercises conscientiously that night and the next day, but only the exceptional parent continued with them daily and the results were poor and disheartening. Often I would see the same child some six months later, and detect no improvement, many times the condition would be aggravated. Then I thought that if I could get the cooperation of an expert in exercises for posture correction, together we might be able to get good results.

Fortunately I was able to obtain the help of Elizabeth Just, who had given corrective exercise for postural defects at the New York Babies Hospital and Temple University Hospital in Philadelphia. Together we worked out a series of standard, or routine exercises for the common postural defects—knock-knee, weak feet, lordosis, pot-belly, lateral curve of spine, and round shoulders. These are given later in this article. One afternoon each week, Mrs. Just came to my office, and in the presence of the parent, under my guidance worked with the children who had postural defects. The mother was then given a written copy of the exercises to be done daily with her child (the standard series having been modified to meet the individual child's needs). She was instructed to do them in the early morning or afternoon and not at bedtime when the child is usually fatigued, and its muscle elasticity diminished. In severe deformities, weekly visits to the office for a check-up and slight changes in the exercises were necessary, but in most

instances attendance every two weeks or at even less frequent intervals sufficed. These were continued for from two months to one and one-half years. Children with the same postural deformity were given the exercises as a group whenever possible. Any other defects found in these children under discussion, such as anemia, defective vision, excess activity, or malnutrition were corrected as far as possible. Many of the children had been under my care without improvement of their posture, for several years before we undertook to give them regular supervised exercises. Of the twenty-four children we followed twelve were less than four years old, six between three and six, and eight were over six and under eleven years of age. The defects in posture were divided as follows: Thirteen children had flat feet, ten protruding abdomens, eight knock-knees, five lordosis or sway back, five forward shoulders, three held their heads forward, three had lateral curvature of the spine, and two had poor chest development. Postural deformities seldom occur in only one part of the body at a time, and most of the children had more than one defect.

Our results were so good that I was encouraged to undertake a similar activity in behalf of the children with postural defects under my care at the Winifred Wheeler Day Nursery. All the nursery children had been under my observation weekly for from six months to several years previous, when no supervised exercises had been given them, and only rarely would a postural defect right itself. Twenty-six children were selected for the experiment. Five of these were less than two years old, fourteen were at kindergarten, between four and six years of age, and seven school children above six years were included. Of this group ten had knock-knees, eleven pot bellies, five round or forward shoulders, four lateral curvature of the spine, five sway back or lordosis, five flat feet, one

8 Hobby horse (1) Massage every morning and night. Forcibly straighten 10 minutes daily (2) Bicycle riding Horseback riding

Lordosis

- 1 Limbering-up exercises
- 2 Stand at "attention"
- 3 Stand against wall and try to touch wall with entire spine
- 4 Raise arms above head, bend forward (straight knees) touch floor with hands Touch knees with your nose
- 5 "March" bending knees way up
- 6 "High kick"
- 7 (a) Sit on floor, straight back, straight knees (b) Place hands behind neck, pulling elbows back and shoulder blades together (c) Rest, placing hands behind you on the floor Then repeat exercises (d) Repeat whole ten times
- 8 "Attention"

Exercises for Weak Feet

- 1 Toe raising
- 2 Toe raising, deep knee-bending, return to toe raising heels down (five times)
- 3 Walk in straight line for five minutes in such manner that when the heel strikes the floor, the rest of the foot pivots inward forty-five degrees
- 4 Turn feet on outer border, return (repeat ten times)
- 5 Raise toes off floor
- 6 Walk on tip-toes (feet turned slightly inwards) as much as possible.
- 7 Lie on back, place sole against sole, knees bent, stretch (repeat five times)
- 8 Ostrich step
- 9 Pick up a dozen marbles with toes and put into a cup

Curve

- 1 Place right hand behind neck, left hand on hip or higher Then bend to the left.
- 2 Make fists of hands, place right fist on top of your head, left behind your back, then bend to your left and push with your fists in different directions
- 3 Lie on right side, have someone hold your feet down, then place right hand behind neck, left hand on hip then raise off bed.
- 4 Sit on floor, straight legs, straight back. Have someone take hold of your hands and pull them up hard This is a left dorsal curve, chart. If patient has a curvature to the right, the exercise should be taken in the opposite direction.

Exercises for Round Shoulders

- 1 Arm swinging, head up
- 2 Fold hands together behind back, pull shoulder blades together
- 3 Sit with a wand or broomstick across back with arms pulled back by this
- 4 Place hands behind neck and pull elbows as far back and up as you can
- 5 Make fists of hands, cross hands across chest, then throw arms out-back-up (ten times)
- 6 Lie on stomach Have someone hold your feet down Then place hands behind neck and raise off bed (or floor), pulling elbows up and back as far as possible
- 7 Walk with palms of hands turned out. In order to get full benefit from these exercises, they should be done using effort so that the exerciser feels a strain at the end of each movement They should be done effortlessly

Abdominal Exercises for Pot-Belly

(Always start with a few limbering-up exercises)

- 1 Lying down (a) Pull abdomen in as much as you can (b) Expand it Watch breathing This exercise is more effective if a weight such as a book is placed on the abdomen (ten times)
 - 2 Bicycling in the air
 - 3 Lie on floor Sit up without assistance or elbows
 - 4 (a) Stand along side of wall Try to touch it with the entire spine (b) Take arms down Take step away from the wall Hold that posture.
 - 5 Swing down, touch floor with hands, without bending knees
 - 6 Deep-knee-bending Place hands between knees on floor Then with a quick jump, throw legs out and back holding stomach in and contract buttock muscles
- (Always finish with a few breathing exercises)

Summary

1 Twenty-six children with postural defects at a Day Nursery and twenty-four patients in private practice were given corrective exercises regularly by a posture worker under the supervision of a pediatricist The age varied between one and one-half years and eleven years Many of these children had these posture defects for several years without improvement before this treatment was started The exercises were conducted twice

Comment

It should be kept in mind that many of these children were under my observation for a long time before we started the supervised exercises, without any improvement in their posture. The cost of having a posture worker in the office once weekly is moderate, and more than offset by the fees received, as well as the tremendous satisfaction in rendering valuable service. Many orthopedists know the value of such an addition to the office staff, but the pediatrician and general practitioner has yet to learn it. Armin Klein¹⁻³ for many years has advocated posture clinics at the dispensaries and schools. In my own practice the posture worker was not only used to correct the postural deformities reported, as many children with Spastic paralysis, fractures, and tightened ligaments can be helped by supervised exercises. In one child with leg atrophy resulting from a hysterical contracture of the gastrocnemius, the muscle's size was restored and further atrophy prevented while his psychiatric treatment was pursued.

All the children, both in the private practice group and in the Day Nursery Group, received some benefit from the exercises, with the exception of one child at the nursery who did not have the exercises for more than two months. One child in the private practice series has only attended the exercise class once and really serves as a control. His mother was a school teacher and he did not do the exercises regularly. Of the twenty-four children treated at the office, nine were entirely cured of all their postural defects, thirteen other children showed marked improvement in posture, five of which were entirely cured of one or more defects, but still require exercises to correct others. Of the twenty-six Day Nursery children, seven were cured entirely, five others showed marked improvement or were almost cured, eight improved moderately, and six were only slightly benefited. The best results were obtained in the groups under six years of age, indicating that the earlier one starts exercising these children the easier it is to effect a quick cure. The children in the private practice group did better largely due to more individual

attention in the home. It will also be noted that lateral curvature of the spine and holding the head forward were readily cured, and that flat feet and knock-knees were almost entirely cured in about eighty-five percent of the cases. The mother of two children, who held their heads forward was certain that this was a hereditary trait as the father walked with his head forward ever since she could remember. However, within two months these children, six and eight years old respectively, had excellent posture, and have continued thus for the last year and a half. Pot-belly also responds well to exercises, over half were moderately or greatly improved in the Day Nursery group, and all of the private practice group showed improvement excepting the boy who did not take the exercises more than once. Half of this group were entirely cured. One of the boys who had poor chest development had a congenital stenosis of the larynx which caused the defect, his larynx is now normal. His chest is almost normal now, in contrast to the marked sternal retraction of two years ago, but he still has outward flaring of the lower ribs.

Undoubtedly, the above results could be improved upon with more frequent sessions. Also, it is well to remember that correcting the standing posture alone is not enough. We should try to improve the manner⁴ of walking. A good dancing master who has a knowledge of postural deformities can be of great service to these children.

Exercises for Knock-knee

- 1 (a) Massage and (b) Press knee out. Combine with exercises for weak feet.
- 2 Lie on back. Bend knee up and at the same time out aside from hipline. When stretching leg use resistance for strength.
- 3 Feet apart, toes pointed, knees stiff. Raise legs up slowly, return, repeat three times.
- 4 Put feet sole to sole, bend knees, return five times.
- 5 Lie on back, turn feet out from hip, then turn them back (repeat five times).
- 6 Standing—Place one foot on chair (hands on hips) keep knee straight, then bend forward, trying to touch knee with nose.
- 7 Stand and try to press calves of legs together.

8. Hobby horse. (1) Massage every morning and night. Forcibly straighten 10 minutes daily (2) Bicycle riding Horseback riding

Lordosis

- 1 Limbering-up exercises
2. Stand at "attention"
- 3 Stand against wall and try to touch wall with entire spine.
- 4 Raise arms above head, bend forward (straight knees) touch floor with hands Touch knees with your nose.
- 5 "March" bending knees way up
- 6 "High kick."
- 7 (a) Sit on floor, straight back, straight knees (b) Place hands behind neck, pulling elbows back and shoulder blades together (c) Rest, placing hands behind you on the floor Then repeat exercises (d) Repeat whole ten times
- 8 "Attention."

Exercises for Weak Feet

- 1 Toe raising
2. Toe raising, deep knee-bending, return to toe raising heels down (five times)
- 3 Walk in straight line for five minutes in such manner that when the heel strikes the floor, the rest of the foot pivots inward forty-five degrees
- 4 Turn feet on outer border, return (repeat ten times)
- 5 Raise toes off floor
- 6 Walk on tip-toes (feet turned slightly inwards) as much as possible.
- 7 Lie on back, place sole against sole, knees bent, stretch (repeat five times)
- 8 Ostrich step
- 9 Pick up a dozen marbles with toes and put into a cup

Curve

- 1 Place right hand behind neck, left hand on hip or higher Then bend to the left.
2. Make fists of hands, place right fist on top of your head, left behind your back then bend to your left and push with your fists in different directions
- 3 Lie on right side, have someone hold your feet down, then place right hand behind neck, left hand on hip then raise off bed.
- 4 Sit on floor, straight legs, straight back. Have someone take hold of your hands and pull them up hard This is a left dorsal curve, chart. If patient has a curvature to the right, the exercise should be taken in the opposite direction.

Exercises for Round Shoulders

- 1 Arm swinging, head up
- 2 Fold hands together behind back, pull shoulder blades together
- 3 Sit with a wand or broomstick across back with arms pulled back by this
- 4 Place hands behind neck and pull elbows as far back and up as you can.
- 5 Make fists of hands, cross hands across chest, then throw arms out-back-up (ten times).
- 6 Lie on stomach Have someone hold your feet down. Then place hands behind neck and raise off bed (or floor), pulling elbows up and back as far as possible.
- 7 Walk with palms of hands turned out. In order to get full benefit from these exercises, they should be done using effort so that the exerciser feels a strain at the end of each movement. They should be done effortlessly

Abdominal Exercises for Pot-Belly

PICKING THE RIGHT OFFICE ATTENDANT

A doctor's practice may be helped or marred by his choice of an office attendant. To hire just a young lady for your office, who has no special qualifications beyond her good personal appearance, is a big mistake, declares Dr L R Effler, of Toledo, in the *Ohio State Medical Journal*. She must be a help to you in more ways than wearing a nice, white uniform if you expect to impress people of the right class and see your business go forward by leaps and bounds.

To take a young high school girl into your office just because you can hire her cheaply is no asset. She will cause you many gray hairs in her training-process. Naturally, of course, there are exceptions to this rule. This is especially so if such a young lady has promise far above the average. In general, your office attendant should be mature enough to be beyond the giddy stage.

It is much easier to hire a girl who is already trained. It becomes only a question then of whether she fits into your or your patients' personalities.

The nature of your business must decide whether you need a "trained nurse" or a "trained secretary."

If your work is mostly technical and demands both assistance and a large use of instruments, you need a nurse. This is especially true in ear, nose, and throat practice. In this field, both examination and treatment may be somewhat painful because you are dealing with organs of special sense. Steadying of the head by a competent attendant gives a patient a feeling of greater security. Moreover, the

sight of blood or pus or a fainting patient is "old stuff" to a trained nurse, whereas, to a trained secretary, they may be the cause of shudders and a weak stomach on her part when you need her most.

Lastly, a trained nurse will know instinctively not only the routine of instrument-sterilization but also the fine points of oiling and putting the instruments away in good condition for a future day.

If your work is mostly non-technical and entails only the routine of examination, you may not need a trained nurse but a trained secretary. In other words, her business with the patient may begin and end with ushering the patient in and out of your sanctum. For the rest, her duties are concerned largely with your dictation of letters and reports and the keeping of your books and accounts.

The more enterprising nurses have long since realized that their field is overcrowded, that they cannot stop with the mere winning of an R N degree, but that they must go on either into postgraduate work or fit themselves with stenography and typing for secretarial duties in doctors' offices. If a trained nurse has not shown enough enterprise and foresight to do these things, she will be of very little practical use to you.

All things considered, the trained nurse, who at one moment can assist you competently in your medico-surgical office needs and at the next moment can handle your secretarial wants efficiently, makes an ideal combination and wins first place as a doctor's office attendant.

EFFECTS OF SO-CALLED ENSOLS ON NORMAL THYROID AND TESTICULAR TISSUE

W T POMMERENKE, M D, Rochester

From the Department of Obstetrics and Gynecology, the University of Rochester School of Medicine and Dentistry

Introduction

Enthusiasm over the use of various bacterial preparations in the treatment of malignant disease has experienced cyclic ascendancy and descendancy following the announcement, some forty years ago, by Coley¹ that certain tumors responded favorably to the use of these products. Recently Connell² resuscitated the concept that, after all, the problem of cancer therapy might lie in the realm of physiological bacteriology. About six years ago Connell became interested in the observation that needling the lens would in many cases cause disappearance of the cataract, presumably due to ferments present in the aqueous humor. The lytic effects of these ferments were not entirely specific however, since when they were injected into the lens of the living subject, they caused not only destruction of the lens, but also of other parts of the eye.

The thought of using a proteolytic organism which would generate different kinds of enzymes depending on the particular kind of media on which it grew presented itself. Specificity of action of the enzymes might then be expected to follow the need of the organism to cause breakdown of the precise type of protein present in the medium. Such a solution was prepared by inoculating with *B. histolyticus*, a medium containing only lens protein. A sterile filtrate of this solution was found to digest *in vitro* lens protein, but not casein or gelatin. It is easy to understand why the idea occurred to Connell that the same principle might be applied to the treatment of cancer, and in an early experiment he inoculated with *B. histolyticus* a piece of scirrhous carcinoma immersed in salt solution. After a period of incubation the cancer cells were observed to be digested. The sterile filtrate, obtained by passing the fluid through a Berkefeld candle was found to produce "much more rapid lysis of the cancer cells than took place in the con-

trol tubes undergoing sterile autolysis." The employment of these so-called "ensols" in the treatment of human cancer was a natural consequence of these experiments. Among the favorable results reported by Connell following this type of therapy were (1) disappearance of cachexia and gain in weight, (2) arrest, softening, and absorption of visible tumor growth, (3) decrease in the amount of pain with resultant diminution in the quantity of sedatives required.

The degree of amelioration which Connell claimed for ensol seemed distinctly encouraging and clearly demanded that this work be continued. If the premises on which this line of therapy be correct, would not theoretical considerations suggest the formulation of a more general principle along with a more extended biological application? If an effective ensol for lens substance and tumor tissue can be prepared, why not one for an over-active thyroid or adrenal gland, or against the acid secreting cells in the stomach, against leukemia, or even against specific bacteria?

Gye³ using filtrates prepared by Connell's method was able to observe no effect on the growth of mouse tumors. Pommerenke⁴ found that the injection of a sterile filtrate of *B. histolyticus* growing on the Brown-Pearce rabbit epithelioma had no apparent effect on the rate of growth of this tumor or upon its microscopic appearance. Even when the tumor was propagated through two generations of hosts, both of which had received injections of the filtrate before and after inoculation with the tumor, its highly malignant nature was not halted.

Hoping to gain further information concerning the application of ensols to different types of tissues, the following experiments were undertaken.

Experimental

Six healthy young adult male rabbits, weighing 3-3.5 kilograms each, underwent

right hemithyroidectomy. Because of the small size of the glands, the specimens were pooled. These were handled aseptically, placed in thirty-five c.c. of 85 per cent sodium chloride solution, inoculated with *B. histolyticus* (American type culture collection #611), incubated anaerobically under a layer of petrolatum at 37.5° C in a manner similar to that described by Connell. The sterile filtrate was then injected daily into three of these rabbits, each rabbit receiving thirty-two doses of three c.c. each by the intravenous route. Although no total energy exchange studies were undertaken, the animals remained in good health and vigor. Their weight remained quite constant and they were apparently possessed of enough functioning thyroid tissue to prevent the manifest symptom of myxedema. The experimental rabbits could not be grossly distinguished from the controls.

On the day of the last filtrate injection one of the three treated rabbits and one of the controls were killed and the remaining halves of the thyroid gland removed. A similar procedure was carried out on the four remaining rabbits five days later. The glands of the animals which had been injected were compared macroscopically and microscopically with those of the controls, but no significantly discernible difference could be recognized. This experiment therefore failed to demonstrate an antithyroid ensol.

Four healthy adult male rabbits whose fertility had been established underwent unilateral castration. From their testes, isoenols were prepared in the manner prescribed above. Each rabbit then received from thirty-five to forty-two daily intravenous injections of 3 c.c. each of the filtrate prepared from his own testis before again serving the same two does with which he previously demonstrated his fer-

tility. During this time the animals remained healthy, normally active, and sexually vigorous. Each of the eight does again became pregnant and bore normal appearing litters of three to seven young each. The young thrived and were weaned in due time. The fertile matings occurred on the first, second, third, seventh, eleventh, twelfth, eighteenth, and twenty-sixth days respectively after cessation of the injections. The remaining testis of each of the four rabbits was removed on the fourteenth, sixteenth, twentieth, and thirty-second day respectively after the last injection, and the stained section microscopically compared with the one from the other testis which had been removed earlier. All slides showed active spermatogenesis in thick-walled seminiferous tubules. Innumerable spermatozoa were noted within the lumina. No degenerative changes were recognized either in the germinal or interstitial tissues. Here again the experiment failed to demonstrate a bacterial filtrate specifically affecting the testis.

Summary

A saline solution containing thyroid gland and testicular tissue of the rabbit was inoculated with *B. histolyticus* and the sterile filtrate injected into the same animals which supplied these tissues. These injections produced no recognizable changes in the general physical condition of the animals or upon the microscopic appearance of the remaining thyroid gland or testicular tissue.

WHERE TO PUT IT

Lena Svenstrum had worked for two years for a certain family of high social aspirations and had been kept quite busy. Finally it was decided that all members of the household must be vaccinated, but the question came up, where to vaccinate Lena so it would not interfere with her work.

"How about an arm?" asked the doctor.

"I'm afraid she would not be able to do the dusting and other housework," said the lady of the house.

"The leg should be the place then," sug-

gested the doctor.

"That would interfere too," objected the lady, "because she has to get down on her knees every day to do the scrubbing."

"Well," exclaimed the M.D., scratching his head, "I don't know, I'm sure, just where to vaccinate her so it won't interfere with some of her work. Have you any suggestions, Lena?"

"Vell," replied Lena, pondering deeply. "Ay don't get mooch time to sit down!"—*Ills. Med. Jour.*

DIABETES MELLITUS

Impotent Insulin a Factor in Supposed Insulin Fast Diabetes— Report of Cases

HENRY M FEINBLATT, M D and EDGAR FERGUSON, Brooklyn

From the Metabolic Laboratory of the Kings County Hospital, the Long Island College of
Medicine Division

Over the past few years a number of instances have been reported where the previously adequately controlled diabetic showed marked fluctuations in the diabetic state with severe ketosis, coma, and in some cases, death

Through our diabetic clinic, we have had occasion to study the incidence of the so-called insulin fast group

Insulin Assay

A review of the literature indicates no reference to insulin assay in the insulin fast cases of diabetes reported

For the past year we have experimented with a number of insulin precipitants and have found that a simple colorimetric determination with precipitate of insulin could be readily utilized for accurate assay

A simple procedure for insulin assay for hospital and private practice is made as follows

Standard a solution of crystalline insulin U-40

1 c.c. unknown in colorimetric tube

Add 5 c.c. protamine solution

1 c.c. standard in second colorimetric tube

Add 5 c.c. protamine solution

Read in colorimeter

Hexamine B P 64% may be used instead of protamine.

If standard is set at ten, and unknown reads ten, unknown contains forty units of insulin per c.c. and is one hundred per cent potent. If unknown reads at twenty, insulin content is twenty units per c.c. and is fifty per cent potent

Any of the standard colorimeters may be used for this purpose. We have used, with equal accuracy, the Helge, the Duboscque, and the Electric Photometer

This precipitate test was made on fifty vials of fresh insulin taken from fifteen different lots. The minimum reading in this group of tests was ninety-seven per cent and the maximum reading was one hundred and ten per cent

Biological Check

Rabbit subjects Four rabbits, each weighing two kg. were given fifteen clinical units of the insulin subcutaneously. Blood sugars were examined before injection and showed an average of 138 mg. There was no appreciable fluctuation in the blood sugars examined one hour after injection of impotent insulin

One of the rabbits was given two additional doses of fifteen clinical units or a total of forty-five clinical units. After twelve hours, there were no symptoms

Twenty-four hours later the rabbits were each given fifteen clinical units of fresh insulin which showed a potency of between ninety-seven and one hundred and ten per cent. Shock and death resulted in an average of three and one-half hours

Human subject White male, age twenty-four, controlled by seventy units of insulin daily, showed an average morning blood sugar of 330 mg

On the first day, at 8 A.M., he received 170 grams carbohydrates with no insulin. At 11 A.M., blood sugar was 700 mg

On the second day, at 8 A.M., he received 170 grams carbohydrates and forty-five units of insulin (100% potent). At 11 A.M., blood sugar was 285 mg

On the third day, at 8 A.M., he received 170 grams carbohydrates and forty-five units insulin X. Blood sugar, at 11 A.M., was 715 mg

Thus insulin X was proven of 0% potency by the precipitate test, the rabbit test, and the human test

Case Reports

CASE 1 White male, age eighteen, height 62", weight eighty-five lb., has been a known diabetic for five years, and under our observation for the past year. During this time, he was sustained on C 150, P 70, F 90, Insulin 10-0-10, blood sugar approximated 235 mg

December 25, patient was admitted to hospital in coma with glycosuria and heavy ketonuria.

On examination, insulin used prior to coma showed a potency of thirty-seven per cent so that instead of 10-0-10 units, he was actually getting 37-0-37 units

December 27, patient was stabilized on original diet with 45-40-45 units of insulin. This dosage was maintained for a week. Morning blood sugars approximated 266 mg

On examination, this insulin showed a potency of twenty per cent so that instead of 45-40-45, he was actually getting 9-8-9 units

January 14, patient was given fresh standard insulin with a potency of 108%. He reluctantly agreed to take just 10-0-10 units instead of 45-40-45 and was adequately controlled. Blood sugar approximated 148 mg

January 18, patient began to take fifteen units protamine zinc insulin daily. Morning blood sugar approximated 105 mg. Patient felt well and was in good physical condition

CASE 2 White female, age forty, height 65", weight 164 lb, has been a known diabetic for seventeen years, and under our observation for the past two years. During this time she was sustained on C 110, P 70, F 50, Insulin 50-10-30, blood sugar approximated 290 mg

January 18, patient was admitted to hospital in coma with glycosuria and heavy ketonuria. On admittance she was given fifty units protamine zinc insulin. During the next twenty-four hours she received 160 units standard insulin. Twelve hours after admittance, glycosuria and ketonuria cleared

January 19, patient was stabilized on original diet with ninety units protamine zinc insulin daily

On examination, insulin used prior to coma showed a potency of 0%

It is interesting to note that patient, while at the hospital received 210 units of insulin, which is exactly the amount lacking before coma

CASE 3 White female, age fifteen, height 60", weight 110 lb, has been a known diabetic for five years, and under our observation for the past two years. During this time, she was sustained on C 250, P 70, F 70, blood sugar approximated 290 mg

Patient was admitted to hospital in coma. During the first twenty-four hours, she received 3000 cc fluid, 100 grams glucose, fifty units protamine zinc insulin, and 160 units standard insulin

On examination, insulin used prior to coma showed a potency of 0%

Patient was stabilized on original diet with ninety units protamine zinc insulin.

CASE 4 White male, age twenty-four, height 72", weight 160 lb, has been a known diabetic for twelve years, and under our observation for the past five years. During this time, he was sustained on C 420, P 90, F 80, Insulin 45-0-35, blood sugar ranged from 330 to 380 mg

January 25, patient complained of glycosuria and heavy ketonuria. On examination, insulin showed a potency of 0%

February 4, patient was stabilized on C 150, P 70, F 70, and fifty-five units protamine zinc insulin daily

CASE 5 White female, age fifty-nine, height 61", weight 100 lb, has been a known diabetic for four years. During this time, she was sustained on C 150, P 90, F 90, Insulin 25-0-20

January 25, patient was admitted to hospital in coma with glycosuria and ketonuria. She received 150 units insulin daily for three days

On examination, insulin used prior to coma showed a potency of 0%

Patient was stabilized on C 150, P 70, F 70, and fifty-five units protamine zinc insulin daily

CASE 6 White female, age seventeen, height 60", weight 115 lb, has been a known diabetic for three years, and under our observation for the past two years. During this time, she was sustained on C 234, P 83, F 98, Insulin 45-0-45, blood sugar approximated 625 mg

Numerous morning blood sugars were examined and showed levels of 500 mg or higher

On February 28, 1936, a blood sugar time curve was made. (Chart I)

September 13, patient was admitted to hospital in coma and was given 2500 c.c. fluid and 170 units insulin. Urine showed four plus sugar and heavy acetone. Patient died

Samples of insulin from vials of the same lot as used by patient showed a maximum potency of twenty per cent.

Autopsy was not obtained but assay of insulin potency would indicate that the patient died from diabetes and lack of insulin control

CASE 7 White female, age seventeen, height 60", weight 127 lb, has been a known diabetic for nine years, and under our observation for the past two years

For the first eight months of 1936, she

was sustained on C 160, P 60, F 30, and 135 units standard insulin daily. For the latter part of 1936 and the beginning of 1937 she was sustained on the same diet with 150 units protamine zinc insulin daily. Patient was going to school and carrying on normal activity.

During the past two years, she had four episodes of ketonuria and ketonemia followed by severe acidosis associated with either intense nausea or nausea and vomiting. A close investigation revealed no history of cyclic vomiting.

January 19, 1937 patient was admitted to hospital in coma with Kussmaul breathing,

CASE 8 White female, age fifty-six, height 62", weight 115 lb, has been a known diabetic for eighteen years, and under our observation for the past 1½ years. During this time, she was sustained on C 150, P 70, F 100, Insulin 65-0-40.

August 21, patient was admitted to hospital in coma. During the first sixty hours she was given 1850 units of insulin. Glycosuria and ketonuria persisted. She received from 200 to 400 units of insulin and hypodermoclysis daily but showed no sign of recovery.

On repeated examination, urine showed four plus acetone and twenty-five mg urea

CHART I—BLOOD SUGAR TIME CURVE
(CASE 6) DOSE U 45-0-45

nausea, and acetone breath. Urine showed four plus sugar and four plus acetone. Acidosis gradually increased before onset of coma and glycosuria.

During the first twenty-four hours, she was given 150 units protamine zinc insulin and 400 units crystalline insulin. Acetone and sugar cleared and patient showed full recovery.

February 20, patient was stabilized on original diet with 150 units protamine zinc insulin which was taken in one dose. Blood sugars were examined twenty-four hours after injection. Blood sugar was seventy-six mg.

February 21 blood sugar was ninety-six mg.

February 22 blood sugar was fifty-four mg.

On examination, insulin showed a potency of 100%.

nitrogen. Blood sugar ranged from 76 to 500 mg.

Patient died of B. Welchii infection of the thigh one month after admission to hospital.

On examination, samples of insulin from vials of the same lot as used by patient showed a maximum potency of twenty per cent.

CASE 9 White female, age fifty-nine, was brought to the hospital complaining of progressive asthenia, polyphagia, polydipsia, and loss of weight. She had been in the hospital one year before with the same complaints and responded to routine treatment.

While under observation, patient lost rapidly in her tolerance for food despite dietetic and insulin treatment.

On admittance to hospital, breath was strongly acetone, tongue parched, mucous

membranes dry and pale Thyroid palpable Chest was sunken Breasts were atrophied Heart was hypertrophic Abdomen was scaphoid with tenderness in the right upper quadrant Gall-bladder was full Extremities were poorly developed Tendon-jerks were absent Larger blood vessels were thickened and tortuous

Blood sugar was 375 mg, urea nitrogen forty-two Urine showed four plus sugar and ketone bodies

In the course of a day she was given 145 units of insulin but there was no change in sugar content of either the blood or the urine.

On the following day, she was given 265 units of insulin This dosage was maintained for a week and patient showed marked improvement in general physical condition Glycosuria was less severe

She was placed on C 180, P 70, F 90, Insulin 80-80-80 Blood sugar was 390 mg Urine showed three and one-half per cent sugar and ketone bodies

Diet was changed to C 120, P 50, F 50 and insulin dosage to 190 units daily Acidosis became more severe and insulin dosage was changed to 210 units daily This dosage was maintained for two weeks Blood sugar persisted between 250 and 350 mg Urine sugar ranged from two to three per cent

Repeated attempts to increase insulin dosage resulted in insulin shock, and in spite of treatment, hyperglycemia and acidosis persisted Patient died of pneumonia

Literature and Discussion

The terms insulin resistant, insulin fast, and diabetes resistant to insulin have been used by many writers^{2,3,8,12} without any agreement as to the definition of these terms

Our own experience with rabbit reaction to insulin corresponds to that reported by other workers^{1,8} We have observed marked variations in the effect of insulin on carbohydrate metabolism and glycemic responses in the individual human as in the individual rabbit

The commercial houses recognize this factor, and calculate an average of the reactions of each rabbit out of a group of 50 or 100 rabbits for each potency test

MacBryde³ calls attention to the incidence of relative resistance to insulin in uncomplicated diabetes mellitus and reports three cases which he so classifies

Altschuler and Gould² report, as insulin

resistant, a case which showed tumor of the pituitary on autopsy In the case they reported, a thirty per cent increase in insulin dosage resulted in a twenty per cent drop in blood sugar In this case, the carbohydrate insulin ratio was one gram carbohydrates per unit insulin

The writers have repeatedly emphasized the relationship between fatty liver and cyclic vomiting^{6,7,13} but we have never observed any relationship between fatty liver and impaired sugar tolerance

Ross⁵ describes thirteen cases of diminished sugar tolerance in alimentary diseases in infancy with rapid recovery on liver therapy He attributed the impaired sugar tolerance to the inability of the liver to produce insulin kinase

While it can readily be seen that a fatty liver would favor a nondiabetic ketosis, it is difficult to see how it would favor hyperglycemia

Out of a group of 500 insulin treated diabetics, 100 of which are of the juvenile type, Case 7 was the only inexplicable instance of acute exacerbation of the diabetic state

Case 9 was reported by Feinblatt⁴ and was included in this series because of the similarity of the clinical picture

Acromegaly

B K., white female, age fifty-four, height 60", weight 170 lb., was a progressive acromegalic Thyroidectomy was performed in 1936 While under observation for acromegaly, patient developed polyuria, loss of weight, thirst, hunger, glycosuria, and hyperglycemia

She was stabilized on C 200, P 70, F 70, and 20 units protamine zinc insulin daily Patient was adequately controlled on this regime Morning blood sugar, on several examinations, was eighty mg

Loss of Insulin Potency

Careful investigation was made of the factors that were pertinent to the loss of insulin potency in the above cases The only consistent factor was improper storage In all cases, the lack of proper refrigeration was the underlying factor in deterioration

Of the nine cases reported in this series, seven were admitted to the hos-

pital during acute exacerbation of the diabetic state due to the use of an impotent insulin

In Cases 6 and 8, the insulin was examined for potency after death. Samples from vials of the same lots as used by patients showed a maximum potency of twenty per cent.

In Case 6, (seventeen year old girl) autopsy was not performed but assay of insulin would indicate that patient died from diabetes and lack of insulin control.

In four of the other five cases where insulin assay was calculated, insulin showed potency of 0%, and in

the other case potency was twenty per cent. In these five cases, the use of crystalline insulin resulted in immediate and complete recovery.

Summary

1 Nine cases of diabetes mellitus with acute exacerbation of the diabetic state described. Insulin assay showed impotent insulin in seven of these cases.

2 Case of acromegaly, insulin sensitive.

3 A simple quantitative method for insulin assay presented.

Connecticut Clinical Congress

The annual Clinical Congress of the Connecticut State Medical Society, which was attended last year by 633 physicians from ten states, will be held this year in New Haven on Tuesday, Wednesday, and Thursday, September 21, 22, 23. The registration fee for the entire Congress will be \$2.00. The morning sessions, beginning at 9:30, will be held in the auditorium of the Sterling Law Buildings. The afternoon and evening sessions, beginning at 2:15 and 8:15 respectively, will be held in the buildings of the New Haven Hospital and the Yale School of Medicine. The evening meetings are section meetings which are open to all members of the Congress.

The complete program of the Congress was published on page 1522 of the September 1 issue of this JOURNAL.

Let us ask ourselves quite frankly, Has the medical service in the United States in the last twenty-five years been effective? The final test of medical service is the crude and gross mortality of the people, and we have in the United States a crude mortality less than in any country that has either socialized medicine or compulsory health insurance.

The next question is, Has the practice

The papers read before the Congress or complete abstracts of them will be published in subsequent issues of the *Journal of the Connecticut State Medical Society*.

On Tuesday and Wednesday afternoons members of the Congress will meet for a social hour at the New Haven Medical Association.

Section dinners will take place on the evening of the meeting of the respective sections.

The Women's Medical Society of Connecticut will hold a luncheon meeting in conjunction with the Congress. All women in medicine will be welcome.

Complete program and registration card can be obtained from the Chairman of the Committee of Publicity and Registration, Dr. Maurice J. Strauss, 41 Trumbull Street, New Haven, Conn.

of medicine in the last twenty-five years in the United States been scientific? A medical profession that has produced liver therapy, practically the entire structure of vitamin knowledge, all the information on bone transplantation, and modern orthopedic surgery certainly has a right to be proud of its scientific progress.

—Charles Gordon Heyd, M.D.

RUBIN TEST WITH FATALITY

CHARLES WEITZMAN, M D and MORRIS COHEN, M D, *Brooklyn*

The transuterine insufflation of air or gas has become one of the most useful units in our diagnostic and therapeutic armamentarium

Kelling in 1910 had first used the transperitoneal inflation of air through the abdominal cavity Rubin in 1913, first introduced air into the abdominal cavity through the cervical route¹

Previous to this procedure, if the state of the tubes in a sterile patient were not known, a laparotomy was indicated The value of this test is evident, glandular therapy, dilation and curettage, cervical dilation with stem pessary are futile if the tubes are sealed Practically eleven per cent of female sterility is due to tubal disease In women under twenty-five years it is higher—about fifteen per cent

The method is indicated in all cases of primary sterility, where all the contributing causes have been eliminated, following gonorrheal pelvic inflammations, and following a pelvic exudate where resolution has taken place It can also be used in cases of a previous peritonitis due to an abdominal disease (appendicitis) and in cases of pelvic infection following childbirth The procedure is also of value after operation for unilateral ectopic pregnancy to discover the patency of the other tube, and after salpingostomy for sterility to determine if the operation was successful

The contraindications to the use of the test are very important^{4 5}

1 The test should not be used in acute or subacute inflammations of the cervix and tubes A white blood count, vaginal smear, and sedimentation rate is indicated in case of uncertainty

2 The test should not be done in the menstrual or premenstrual phase, because of the theoretical possibility of endometrial dislocation and consequent formation of chocolate cysts

3 It should not be used in a patient with abnormal bleeding This condition is supposed in some way to favor embolization The test would be contraindicated in severe constitutional diseases, such as severe cardiovascular disease, severe diabetes, or active pulmonary tuberculosis¹

The Rubin Test should be performed three-four days following the menses The technic varies with the clinic, but the apparatus usually consists of a gas tank, usually CO₂, water bottle, cannula for the uterus, and a manometer The volume of gas entering the uterus and eventually the peritoneal cavity should be under 200 c.c. per minute When the patient has patent tubes the pressure goes from forty mm of mercury to about sixty or one hundred in fifteen to thirty seconds and then drops to forty again In non-patent tubes, the pressure rises rapidly to 200 in about thirty seconds, and does not fall rapidly The question of whether one or both tubes are occluded can be determined by the well-defined methods of skiography, auscultation over both sides of the abdomen, and the subjective feel of colicky pain on one or both lower quadrants by the subject³

That the test is not without its dangers has been recognized for a long time by many clinicians, although this is usually denied by Rubin Dr Gerald D Meench reported two cases from the Medical Examiner's office where fatalities resulted In one case after the tubes were found closed by the test, the operator did a dilation and curettage, the patient promptly went into collapse and died The necropsy demonstrated numerous gas bubbles in the femoral vein and the inferior vena cava²

Rubin in analyzing this case believes that the curettage was probably done first, or that it was done so soon after, that the tubes and uterus still contained air in large quantities In another case of sudden death, the gas flowed only when a pressure of 200 mm of mercury was registered The necropsy revealed gas and a turbid fluid when the abdomen was opened, a small tear in the small intestine, and a spot (not a tear) on the uterus The spot was not caused by the cannula and was interpreted as gas perforating the uterus as well as the intestine The official cause of death was surgical shock⁶

Severe syncopal reactions have been

reported in the literature many more times than death. Rongy had two cases which went into such severe collapse that the lives of the patients were in extreme danger. Rubin had one patient with a severe syncopal attack which he attributed to a traumatization of the cervix with a cannula and subsequent small air embolization. In Rongy's large series of cases several infections, several pelvic abscesses, and one case of parametritis occurred.⁷ That a jet of gas can take with it bacteria was experimentally proved by Volkmann who tried to copy as near as possible tubal conditions.⁹

Another interesting phenomenon reported was a case of paroxysmal tachycardia following a test, which was apparently due to pressure of a large gas bubble under the left diaphragm, because the tachycardia and the alarming syncopal symptoms subsided on putting the patient in a horizontal position.

Polak also had seen several alarming cases,⁸ and other observers, notably in the foreign literature have observed several deaths due to air embolization.^{9, 10}

To illustrate further that the tubal insufflation test is not entirely innocuous in spite of all due precautions taken, the following case is reported.

Case Report

M. C., middle-aged, obese, Italian female, complained of pain all over her body for one year, as well as weakness and choking sensation in her throat for six months. Spells came on once a month and lasted for ten minutes to one hour. She was obviously a hysterical but otherwise healthy individual.

Obstetrical History. She was married twelve years without having any children. She had had an abortion two months after marriage, with no sequellae. Her periods were irregular before an operation, which consisted of D & C and insertion of pessary two years ago, after which they became regular and lasted for five days. There was no history of genitourinary disease. Her Wassermann was negative and her husband's Wassermann was also negative. Spermatozoa were motile and abundant.

Pelvic Examination. Her uterus was small and adnexa were not palpated. There was no laceration of the cervix and no dis-

charge. The examination was essentially negative.

Five days after the last day of her period a Rubin test was done. The rate of flow of oxygen was 150 c.c. per minute and the pressure read 125 mm. of mercury. The patient suddenly complained of extreme pain, developed a convulsive seizure, and became cyanotic. It appeared as if the patient was having an epileptic attack. Breathing became stertorous, pulse became imperceptible, heart sounds were not heard, and the patient became comatose. The patient ceased to breathe, but under artificial respiration and stimulants, respiration was restored, although it was heavy and labored. Heart sounds became audible after three to four minutes. The condition of coma persisted and the following day a neurological consultation was deemed advisable.

Neurological Consultation. Patient is in deep coma. Pupils are at first contracted but later became more dilated. They react to light promptly. Fundi are negative. No neck rigidity or Kernig. Eyes opened, the right deviated outward and the left inward and down (Skew deviation?). Supraorbital pressure produces no grimacing. Breathing regular, pulse rapid. Upper extremities show no alteration of muscle tone. Tendon reflexes in upper extremities are not obtained. The fingers are partially flexed. Abdominal reflexes are not obtained. There is spasticity of both lower extremities. During the examination, the left leg becomes hypertonic and the foot inverted. Knee and ankle jerks are obtained. The left knee jerk is more active than the right. There is a definite left Babinski. There is a defense withdrawal of both legs to pin prick of soles.

The history of tetanoid type of seizures with at first retraction of head and pes-equinovarus posture of right foot, and the present findings indicate a clinical decerebrate rigidity syndrome, etiology of which is obscure. Further observation is indicated. Spinal tap was done, fluid allowed to escape drop by drop. There was slight pressure.

Test by Dr. Rabiner

Spinal Cell Count 9 cells per cu. mm.
Spinal Fluid Wassermann Negative
Blood Wassermann Negative
Blood Calcium 16 mg%
Blood Sugar 150%
Blood Urea-N 15 mg%

For the next three days the patient's coma deepened and she finally expired.

The blood and urinary findings as well as the blood count were not remarkable.

The necropsy revealed an old bilateral adnexitis, with tubal closure, a left dermoid cyst with the left tube sealed over the cyst and communicating with it by a pin-point opening. The cyst contained air and pale yellow fluid. No obvious opening from the tube wall into the peritoneal cavity on the left side could be found. The right tube showed no opening demonstrable into the peritoneal cavity. The uterine cavity, cervix, and vagina showed no points of injury which might be attributed to sharp instruments. Pelvic veins were not thrombosed or otherwise altered. The urinary bladder and rectum were negative.

Sections of the brain showed recent numerous petechial hemorrhages, all perivascular and limited strictly to the white matter. These were most pronounced in the frontal lobes and internal capsules. The vessels showed numerous ruptures of the wall, these being more pronounced in the more massive hemorrhages.

Aside from this finding the noninvolved vessels in both the gray and white matter showed a mononuclear infiltration of the perivascular spaces. There was no necrotic ring of tissue surrounding the vessel or separating the vessel from the hemorrhagic area, but the tissue peripheral to the hemorrhage was unusually necrotic and showed

a moderate Gitter cell reaction. Similar lesions were found in the white matter of the cerebellum and occasionally one in the medulla. The ventricles were not dilated and their walls showed no changes. There was no unusual sclerosis of the basilar vessels.

Findings Multiple Cerebral Hemorrhages.

Diagnosis Bilateral adnexitis. Dermoid cyst. There was air in both Fallopian tubes and in the dermoid cyst. Air embolism was present. There was no organic cause for embolic phenomenon, i.e. no thrombi, no fat, bacterial, or fibrinous emboli.

Thus we see a fatal result from a supposedly innocuous test, even though due respect was given to all precautions that were considered necessary. It would seem necessary to investigate this serious phenomenon by further study, as a diagnostic procedure should at all times be free from danger and work reliably well.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, DR P H, *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Ancient Beliefs

Generally the belief in the bad influence of some people through their inborn power or faculty to harm by their mere presence or nearness, or by the active use of this ability, is not a sign of mental abnormality. It is one of the old superstitions which constituted the hypothesis, the science of ignorance in ancient humanity. It is one of the explanations of undesired phenomena, like sickness or ill-luck in love or misfortune or death. Along with progressive and real scientific ideas men have dragged through the centuries all sorts of convictions and faiths which now live side by side with the highest and most modern thoughts and achievements.

Many of the most common and most popular superstitions are forms or symptoms of a mass psychoneurosis or give rise to a

psychoneurosis on a huge scale and are extremely contagious. Even some persons who flatter themselves of being above irrational credulity in the occult and immune to such beliefs may be affected by crowd influence, a phenomenon well-known in the study of behavior of the individual as a part of a mob or swept by mob psychology. It is easy to find, therefore, superstitions, religious and others—like so many cobwebs in a perfect palace—among some super-civilized people with the widest culture.

All ideas about life and the world, no matter how humble their origin, if they contain the element of popular appeal, are contagious. So are emotional states. But when such ideas combine with emotions the result is a sweeping epidemic—unless it is confined to endemic proportions.

People who say, as I have often heard, "That man passing there has an evil eye," or "that woman makes you sick only when she looks at your back," or those who cross themselves when seeing a black cat and so on indefinitely, are not mentally deranged. They are just afraid of the many dangers and threats which beset life and they have not discarded the teachings of their environment as to the causes of their insecurity.

But patients suffering from some psychosis employ such existing superstitions whenever their disturbed mental state demands it, just as they take a hold of everything that comes within their sphere of knowledge.

The following case recalled to my memory the first psychopathic case I ever saw. When I came to Vienna to study medicine, after a French preliminary education, I was a mere youth and less interested in anatomy, physiology, botany, etc., than in the courses of some famous professors of law, sociology, philosophy and literature. But I soon discovered *Krafft-Ebing's* sensational course on psychiatry. I was too young and although a special student card was required because of the many laymen who invaded it, I managed to smuggle myself in with somebody else's permit. Naturally I was fascinated both by the teacher and the material and not so much by the homosexual cases, which were rather rarely presented, as by the various forms of *paranoia*. Many of them had a background of superstition, probably because of their Balkanic, Polish, Russian, Galician, Bohemian and Hungarian provenience, and the professor seemed to be particularly fond of them.

A Yugoslav patient had all sorts of pains and they all dated back to the time, several years before, when "an old woman put some drops from a tiny bottle on his left lumbar region."

The story runs like this. He had an angelic heart and one day, pitying this old neighbor who was poor and lonely, called her to his room and let her have all the food she wanted. She came the next day and the next. Then she visited the patient and his cupboard regularly until her daily meal at his house had become an established right. But once he was away and his door was locked and another time he had nothing to give her and, therefore, according to the patient, she planned black revenge. She asked him to kindly fix her kitchen washtub, which he was well able to do. He went there and, while occupied with the work, lying on the floor face down and attentive to an ill-smelling outlet

pipe, he felt the fatal drops. While he never remonstrated and never spoke about it to her, he was certain that he was right.

This *paranoid* necessity, combined with a common and ancient belief, which is rooted in primitive humanity, is due, in this case to a dissatisfied life and to a contempt for his work. He expected to make a pile in this country and was sure to have been destined to better things than those that America was forcing him to do. So his "sickness," "made" by this witch-like person, kept him away from all work. Although he was financially badly off and he was quite unhappy to be "crippled"—"perhaps for life," he added—he evidently preferred this situation to the humiliating condition in which he would have been had he continued in his menial job. This was not only an explanation of his complaint, but the most apparent one.

His belief was not touched in the first interviews. It was taken for granted. Otherwise he would not have come back. But he was told about his inborn resistance to poison and accidents and hurts, about his possible revenge against his enemy by surviving and ignoring her dark magic. He, too, had hidden in himself, some of the same powers, if he were willing to appeal to them and, without going out of his way, he could make use of them to fight his sickness. She was happy to see him suffer. The best way to counteract was to make believe that he did not care, to use autosuggestion as a reply. In order to facilitate this, work was a necessity.

After many angry reactions and rebellions against me, he finally entered my scheme. I succeeded more by incessant reiteration than by actual persuasion. But as he began to improve, his conviction strengthened. Then the result of the analysis which was made while he was unaware, was shown to him and his co-operation became closer.

Meanwhile he actually joined a club of his people and became their secretary, which was both an additional therapy and the cause of a diminishing of his subjective symptoms.

This led to a cure, after a year's work.

But let me add that the reader may get the impression that the favorable results seem to come too easily. In appearance he may be right, but one must not forget that these descriptions are abbreviated and condensed and that each of them represents hard work full of opposition and temporary failure and that the successes only are offered here.

EDITORIALS

Change for the Better

Physicians everywhere in the state are waiting to see whether the Welfare Department's bid for medical review of its proposed new rules governing dispensaries is more than a gesture. It is generally agreed that existing admitting systems are lax and inefficient. Dispensary abuse will not cease until the State Welfare Department prescribes stricter rules and insists that they be enforced.

The dispensary laws provide substantial fines for imposters, but penalties are never imposed, although offenses are common and widespread. As a matter of fact, many dispensaries encourage the visits of ineligible, by the direct method of unethical publicity as well as the indirect invitation of lax admitting systems.

A conscientious and efficient check on applicants for clinic service is essential to protect the taxpayers and physicians against exploitation. This demands the service of skilled, tactful investigators. An untrained clerk, appointed through nepotism or political pull, is not competent to discharge this important duty properly.

Dispensaries are intended for the use of those who cannot purchase private medical service. Overcrowded as they are, they cannot serve the needy properly when their facilities are usurped by patients well able to pay for private care.

If cornered, as occasionally happens, imposters usually plead ignorance of the law. To invalidate such excuses, every admission card should contain a summary of the statutes which the patient should be required to read and sign. This would furnish *prima facie* evidence of guilt in cases of misrepresentation.

Although the dispensary law is essential to the efficient distribution of clinic service to the poor, it is disregarded, not only by unscrupulous individuals but by the hospitals and law enforcement agencies themselves. Organized medicine is glad to cooperate with the State Welfare Department in the formulation of suitable rules for the admission of dispensary patients. This will be of little use, however, unless such rules are strictly enforced.

A Proper Deduction

From Senator Bone of Washington comes a proposal to exempt medical expenses from income taxation. This suggestion is both logical and humane.

Apart from humanitarian considerations, every man, woman, and child has an economic value. Good health is an essential condition of productive man. When sickness occurs, those dependent on earned income suffer a three-fold loss.

Their "plant" is impaired, earnings stop, and they must make an actual outlay for medical expense

Is it not fair to exempt the last from taxation as a necessary expense? The personal exemption now allowed presupposes a minimum essential outlay for food, clothing, and shelter, the budgetary constants. Without these the citizen could not earn the wherewithal to pay taxes. While not as regular, medical costs are equally indispensable—a fundamental business expense if anything is.

In a pithy editorial on this question, the *New York World-Telegram* says, "The Senator sees something queer in present federal income-tax law which allows a man to deduct veterinary expenses for a cow and the cow's value if it dies, but permits no deduction of the medical expenses of a sick wife or even the funeral expenses if she dies." Senator Bone is not alone in finding such an attitude "queer."

Prolonged or serious illness, with its demands on the family purse, is a heavy financial drain on all but the rich. A law which subjects money so expended to income taxation displays a heartless indifference to the people's welfare.

The burden of illness would be considerably lightened, for the low income classes at any rate, if medical expenses were exempt from income tax. Such a provision would give a strong boost to preventive medicine by encouraging periodic health examinations and early recourse to treatment.

Epidemic Diarrhea of the Newborn

Of special interest, within recent years, is the report of outbreaks of epidemic diarrhea which solely involve groups of newborn babies resident in the nurseries of maternity hospitals. The disease carries with it a high mortality (46%). It occurs within the first three weeks of life and has particularly been observed in cities located in the north temperate zone. The onset is usually acute. An appar-

ently thriving infant becomes unusually drowsy and shows a slight elevation in temperature. A watery, yellow stool is noted and vomiting coupled with abdominal distention may occur. This is followed by signs of dehydration and marasmus, the child losing a pound or more in a day. Death is the result of secondary infections in the severe cases, whereas recovery in the milder ones is soon evident in the improvement in the clinical picture. As to postmortem findings, it can at present be said that no lesions of particular significance were found.

In a preliminary consideration of the epidemiology of this condition, Rice at al¹ feel that at present, immediate isolation of the sick infant, closure of the infected nursery, and suspension of maternity service should be carried out until it can be definitely ascertained that there will be no further outbreak. These observers feel that they are dealing with a well-defined clinical entity separate from the other diarrheal disturbances of infancy. Attention is directed to this epidemic disease in order to stimulate the interest of others in contributing to its eradication.

Keto-Acid Treatment of Pyuria

The frequency of *B. coli* infections of the urinary bladder and pelvis, particularly among female children, has led to an intensive search for a specific bacteriostatic agent. It had been demonstrated by Shohl and Janny¹ that when the hydrogen ion concentration of the urine was on the acid side of pH5, a significant inhibition of bacterial growth resulted.

The utilization of this knowledge in the treatment of pyuria was first proposed by Clark and Helmholtz² who

¹ Rice, J. L., Best, W. H., Frant, S. and Abramson, H. *J.A.M.A.*, 109: 475, 1937.

² Shohl, A. T. and Janny, J. H. *J. Urol.* 1: 211, 1917.

³ Clark, A. L. and Helmholtz, H. F. *Proc. Staff Meet. Mayo Clinic* 6: 605, 69, 1931.

succeeded in producing a physiological aciduria by feeding patients a ketogenic diet. The potent factor in this means of therapy is beta-oxybutyric acid. However, when this compound is administered orally, it is broken up into H_2O and CO_2 and hence is rendered ineffective in acidifying the urine. Rosenheim³ suggested the use of mandelic acid and was able to manifest its nontoxicity even when large doses were used.

Since the introduction of mandelic acid as an aid in the management of urinary infections, numerous reports of its efficacy have appeared. The acid itself was used in conjunction with ammonium chloride, but of late the ammonium salt of mandelic acid, ammonium mandelate, has proved of equal value. In employing this drug, careful attention must be given to the daily intake of fluids, the daily dosage, and the acidity of the urine. No more than one liter of water should be taken and the daily dose of ammonium mandelate should be limited to twelve grams daily. The urine acidity should be kept below or at pH5. Contraindications to its use are hematuria, impairment of renal function, and gonorrhea.

CURRENT COMMENT

"THIS NATION HAS HAD ITS DICTATORS and they served their country well. They did it by being dictators in the original and genuine sense, as it was understood by the ancient Romans, who invented the thing and the word.

"Whenever the Romans of the republican period found themselves in an exceptionally uncomfortable jam, they suspended the normal processes of government and invested one outstanding ancient Roman with plenary powers. By prescribed formula the Roman Senate instructed him to see to it 'that the republic suffers no detriment.' But when the emergency was over, the dictator handed in his commission and retired to his farm and his oxen, if his name happened to be Cincinnatus, and the due processes of Roman law came back. There is all the difference in the world between the emergency dicta-

tor, set up by a free people for the very purpose of preserving their liberties, and the permanent dictatorships of the new European models. And it does not make things any better because virtually all these new autocracies love to describe themselves as planned and co-ordinated social systems.

"The original dictator, as the Romans invented him, and as we have used him in this country, without the actual name, was strong medicine, but good medicine. He was a strychnine pill in a cardiac attack. What many of us find it hard to understand, is why people should want to make strychnine pills a part of the regular national dietary, why a nation which has shown a genius for combining freedom in normal times with self-imposed discipline in an emergency should be asked to reorganize its life on a permanent emergency basis. Yet there are well-meaning Americans who have got themselves into this frame of mind, with the best intentions in the world.

"They see social and economic injustice and they want it eliminated, right away. They find clutter and waste in our industries and they want to substitute order and efficiency, at once. In place of an imperfectly balanced and inadequately lubricated nation they want a country that purrs, and hums, and sings, and glistens, like a beautifully tended dynamo in a powerhouse. To get that kind of a country without loss of time, they think we ought to declare a permanent emergency. They think we ought to bring Cincinnatus from his farm and give him a life job.

"The most perfectly planned society that one can think of is a hospital, with the thermometers, and the milligrams, and the charts, and the half slice of dry toast, and the good-looking, soft-voiced nurses moving noiselessly on their appointed rounds. But, despite all the planning and co-ordination and synchronization, who wants to live regularly in a hospital? It offers peace and planning, but it is the peace and planning of a receivership."—From an editorial in *The Saturday Evening Post* of August 28.

"OUR STATISTICIANS DISCUSS the saturation point for population in the same fatalistic vein that bankers used in prophesying a saturation point for automobiles thirty years ago. At any given moment the bankers could prove they were right, but before the period of prophecy drew to a close the situation changed. Someone invented a self-starter, someone built more and better roads.

"Of course, you can't buy babies ready-

³ Rosenheim, M. L. *Lancet*, 1 1032, 1935

made. Nevertheless, the pains and dangers of childbirth seem to be decreasing. Obstetrical science keeps reducing the hazards and saving more of the prospective customers for existence. Also, it is just possible that social evolution may produce a better world with a future so rosy that adults will want many children to share in its blessings. A falling birthrate is to some extent a critique on bad management in high places, passive rebellion against regimes grown too expensive and deadly to inspire complete faith in the national future.

"If political management improves sufficiently to reassure parents that their children will be something more than debt-

bearers and arms-toters, the baby business may again boom in America."—From the column entitled "Progress" in *The Digest* of August 21

"HOW DID THE LEGISLATORS from your district vote on medical bills which were introduced during the past year? If they voted for compulsory sickness insurance you should become acquainted with them. Learn their views before the next election. Let them know that how they vote speaks more eloquently than what they say"—Sound advice from "An Observer" in the August Supplement to the *Saint Louis County Medical Society Bulletin*

1938 Annual Meeting

Scientific Exhibits

New York City, May 9-12

Application blanks for Scientific Exhibits may be secured by medical colleges and hospitals in New York State by writing to the Chairman of the Committee on Scientific Exhibits, Dr William A. Krieger, 103 Hooker Ave., Poughkeepsie.

The plan this year is to have all these

exhibits furnished by hospitals and medical schools instead of by individuals

Motion pictures will not be shown in the same room as the scientific exhibits at the Waldorf-Astoria Hotel, but in a special room of large size allocated for that purpose

DISTRICT BRANCH MEETINGS

The Annual Meetings in 1937 will be held this fall on the following schedule

Sept 21	Sixth District Branch	at Owego
" 22	Seventh " "	" Geneva
" 23	Fifth " "	" Lowville
" 30	Third " "	" Kingston
Oct. 1-2	Fourth " "	" Glens Falls
" 5	First " "	" New York City
" 7	Eighth " "	" Olean
Nov 17	Second " "	" Garden City

HERE COMES THE DRUNKOMETER

If your breath turns a purple fluid blue, then you are drunk, according to a court ruling in Indianapolis as reported by the Associated Press. If your breath will take the paint off the front door, or bend a crowbar, or make a mouse want to fight the cat, that would no doubt be evidence too, but so far the color test is the one accepted by the judge. The dispatch, dated August 11, runs

Readings taken by Dr Rollo N. Harger, state toxicologist, on his "drunkometer"

were accepted as evidence in Municipal Court Wednesday, and Mr and Mrs Ray Gordon, of Denver, were fined \$5 each for intoxication.

The Gordons were subjected to the test following an automobile accident last week.

Dr Harger, inventor of the apparatus, testified the breath of each was blown into toy balloons. The air from the balloons was then expelled into a purple fluid, which turned blue, proving, Dr Harger said, that the couple were intoxicated.

Correspondence

531 Bronx River Road
Yonkers

To the Editor

The law states that all welfare cases must get "adequate medical care." For hundreds of years the medical profession has been the judge of what constituted adequate medical care until recently when bureau officials made their own regulations. The physicians had organized into medical societies and promulgated and generally enforced a code of ethics for the practice of medicine, which for decency and fairness to the patient has found scarcely a counterpart in other professions. Accordingly, the medical societies should still retain the right to decide whether welfare patients are getting adequate medical care, and it is their duty to do so. It works a hardship for a welfare patient to be "yanked out" from the hands of his own doctor into those of an indifferent underpaid salaried physician, or of an indifferent clinic physician, not that there are not many conscientious clinic physicians, but very often they have not the time to work up a case completely. According to ethical practice a patient should be able to see his own physician, who is paid a just fee, as is now being done in compensation cases so successfully, and this should be done in all welfare cases.

In this manner we can still maintain our tradition of good medical care for all. Indifferent medical care of the welfare cases by any physician will only besmirch the good name of our profession. This statement holds true even when the physicians are under governmental control.

Neglect to take action now will result in regimentation schemes by crackpots. Look at the ridiculous bill recently introduced by Senator Lewis providing for the regimentation and enslavement of all the physicians of the country by the federal government, forcing him to treat any welfare case at the latter's demand at a fee set by the government on pain of a huge fine and imprison-

ment. What a paradise for malingerers! If you don't make the call, you will find yourself in the jug, regardless of alibies. Shades of Hippocrates, what is this country coming to anyway! You don't see the lawyers, of whom Senator Lewis is a member, yelling for regimentation. So before it is too late, let the medical societies take action, otherwise we will all be regimented, and pawns of government clerks.

Yours very truly

E H ALLAR, M D

August 14, 1937

2270 Mott Avenue
Far Rockaway

To the Editor

In these modern times, when the race for the almighty dollar seems to have blunted the finer ethics of our professional life, it was indeed an unalloyed and unusual pleasure, to read in your last issue (August 15, page 1448) the sincere eulogy which was paid to the memory of Dr. John H. Wyckoff, former dean of New York University Medical College, by Dr. I. W. Held, who with clear, lucid insight analyzed the motives which actuated and influenced Dr. Wyckoff's life and his work as a teacher, which attracted and held the deep respect of all the medical men who had the privilege of coming into contact with him.

We older men, who have almost finished the struggle for daily sustenance, and who stand in amazement at the ultra-modern business methods which now seem to spell professional success, will certainly be heartened by this eloquent tribute to a past master of medicine who has gone into the Great Beyond and the JOURNAL is to be congratulated upon finding space in its columns for Dr. Held's inspiring letter.

JOSEPH BAUM M D

August 26, 1937

What a flight from reality to suppose that the profession can make any effective inroads on the recalcitrance of human nature when there are 16,000 chiropractors, 7,600 osteopaths, 2,500 naturopaths and 10,000

Christian Science healers taking \$125,000.-000 a year from the American people for unscientific or one track systems of healing

—Charles Gordon Heyd, M D

Society Activities

Proceedings of the Council

The Council of the Medical Society of the State of New York, as prescribed by the Constitution and By-Laws, 1937 revision, began its work immediately at the close of the 1937 meeting of the House of Delegates. It has arranged for the carrying out of the duties outlined in Chapter IV, Sections 9 and 10, of the By-Laws (July 15, 1937 issue of the JOURNAL) which read as follows:

Sec. 9 The duties of the Council shall also include the study and supervision of the following activities:

(a) All Scientific Work presented at each annual meeting

(b) Scientific Exhibits

(c) Medical Education

(d) Journal Management and Publication.

(e) Medical and related research

(f) Arrangements for annual meeting

(g) Preventive Medicine

(h) Public Health

(i) Legislation

(j) Economics

(k) Workmen's Compensation

(l) Health and Welfare Department of State.

(m) Medical Publicity

(n) Hospitals, Clinics and Welfare Agencies

(o) Cooperative relationships with Federal and State Governments, Foundations and other lay groups

(p) Malpractice Defense and Insurance

(q) Any activities not otherwise provided for

Sec. 10 Committees of the Council may include other members of the Society and shall be appointed by the President subject to the approval of the Council. Each committee shall include at least one member of the Council who shall be chairman, except that he need not be chairman for the committee or committees in charge of activities "A", "B" and "F", Chapter IV, Section 11 of the By-Laws. The Membership of committees shall not exceed three including the chairman, except the commit-

tee or committees in charge of activities "A", "B", "D" and "F", Chapter IV, Section 9 of the By-Laws

The Council as constituted for 1937-1938 under the Constitution, Article IV, is as follows:

Charles H. Goodrich, 280 Park Place, Brooklyn, President

William A. Groat, 713 E. Genesee St., Syracuse, President Elect

Floyd S. Winslow, 410 S. Plymouth Ave., Rochester, Past President

Peter Irving, 2 E. 103 Street, New York, Secretary

George W. Kosmah, 23 E. 93 Street, New York, Treasurer

Samuel J. Kopetzky, 71 E. 80 Street, New York, Speaker

Thomas P. Farmer, 206 Sedgwick Drive, Syracuse, Councilor 1937-40

James H. Borrell, 413 Brisbane Bldg., Buffalo, Councilor 1937-40

Augustus J. Hambrook, 40 State St., Troy, Councilor 1937-40

Edward T. Wentworth, 501 Professional Bldg., Rochester, Councilor 1937-39

Oliver W. H. Mitchell, Syracuse College of Medicine, Syracuse, Councilor 1937-39

Thomas H. Cunningham, Insurance Bldg., Glens Falls, Councilor, 1937-39

John J. Masterson, 401-76 St., Brooklyn, Councilor 1937-38

Guy S. Carpenter, Waverly, Councilor, 1937-38

Frederic E. Elliott, 122-76 St. Brooklyn, Councilor 1937-38

The Council re-employed Dr. Joseph S. Lawrence as Executive Officer, Mr. Lorenz J. Brosnan as Counsel, and Mr. Thomas H. Clearwater as Attorney for the ensuing year. The Secretary was employed as General Manager, with duties as outlined in the By-Laws, Chapter VIII.

Council Committees, and three Special Committees directed by the House of Delegates, were appointed by the President with the approval of the Council, as follows:

Scientific Exhibits

William A. Krieger, Chairman, 103 Hooker Ave.
Poughkeepsie
New York

John Henderson, 850 Park Ave.

Scientific Work

Albert F. R. Andresen, Chairman, 88 Sixth Ave.,
Brooklyn

Howard C. Taylor, Jr., 842 Park Ave., New York

Arrangements

Charles A. Anderson, Chairman, 32 Eighth Ave.,
Brooklyn

John L. Bauer, 984 Bushwick Pkwy., Brooklyn

Charles Gordon Heid, 116 E. 53 St., New York

Frederic E. Sondern, 24 W 55 St
 Ralph I. Lloyd, 14 Eighth Ave
 Augustus Harris, 306 Park Place
 Irving Gray, 41 Eastern Pkwy
 Herbert C. Fett, 54 Eighth Ave
 W. G. Frey, Jr., 140 Continental Ave.,
 Forest Hills Garden
 Arthur S. Driscoll, 100 Central Ave. St. George, S I
 Carl A. Hettesheimer
 Charles C. Murphy
 Emil Koffler, 306 E. Tremont Ave
 Clarence G. Bandler, 77 Park Ave.
 Leo F. Simpson, Advisory, 221 Alexander St.,
 Rochester

The General Manager was directed to act to coordinate the work of the Committees on Scientific Exhibits, Scientific Work, and Arrangements for the Annual Meeting

Medical and Related Research

Thomas H. Cunningham, Chairman, Insurance Bldg.,
 Glens Falls
 Frederic E. Sondern, 24 W 55 St

Section and Session Officers 1937-38

Officers who had been elected by the Sections at their annual meetings were recorded with the Council and are here included for reference. The officers for the two new Sections on Orthopedic Surgery and on Pathology and Clinical Pathology, and the officers of the Sessions were appointed by the Council, as is customary

Section on Orthopedic Surgery

Chairman—Samuel Kleinberg, 1 W 85 St New York
 Secretary—Arthur Krida, 791 Park Ave., New York.

Section on Pathology and Clinical Pathology

Chairman—James Ewing Memorial Hospital New York.
 Vice-Chairman—N Chandler Foot 525 E 68 St New York.
 Secretary—M. J Fein, 50 Greene Ave., Brooklyn

Section on Medicine

Chairman—Ralph H Boots, 772 Park Ave., New York.
 Secretary—Byron D Bowen 100 High St, Buffalo

Section on Surgery

Chairman—Benjamin W Seaman, 131 Fulton Ave Hempstead.
 Secretary—Clarence V Costello, 258 Alexander St., Rochester

Section on Obstetrics and Gynecology

Chairman—Goode R. Cheatham, 618 High Ave. Endicott.
 Secretary—William T Kennedy, 79 E. 91 St., New York

Section on Pediatrics

Chairman—John Dorsey Craig 108 E. 68 St., New York.
 Vice-Chairman—Paul W Beaven, 26 So Goodman St., Rochester
 Secretary—Norman L. Hawkins Woolworth Bldg Watertown.

Section on Ophthalmology and Oto Laryngology
 Chairman—Marvin F Jones 121 E. 60 St., New York
 Secretary—Algernon B Reese, 73 E. 71 St., New York.

Section on Neurology and Psychiatry

Chairman—Charles A. McKendree, 140 E 54 St, New York.
 Secretary—Paul H. Garvey Strong Memorial Hosp, Rochester

Section on Dermatology and Syphilology

Chairman—Leo Spiegel 241 W 100 St, New York
 Secretary—Mark Heiman, 713 E. Genesee St Syracuse

Section on Public Health, Hygiene and Sanitation

Chairman—Burke Diefendorf, 51 Grant Ave., Glens Falls
 Vice-Chairman—Chalmer J Longstreet, 95 Oak St, Binghamton
 Secretary—Frank E. Conghlin, State Dept of Health Albany

Section on Urology

Chairman—Albert M Crance, 407 So Main St., Geneva
 Vice-Chairman—Francis N Kimball, 901 Lexington Ave New York.
 Secretary—John E. Heslin 248 State St., Albany

Section on Radiology

Chairman—Clifford R. Orr, 1093 Ellicott St. Buffalo
 Vice-Chairman—William P Howard, 46 Willett St., Albany
 Secretary—Henry K. Taylor 667 Madison Ave., New York.

Section on Industrial Medicine and Surgery

Chairman—William A Sawyer, 343 State St Rochester
 Secretary—Dan Mellen 305 No Washington St., Rome

Session on Physical Therapy

Chairman—Madge C L. McGuinness, 1211 Madison Ave. New York
 Secretary—Harold J Harris, Westport.

Session on Regional and General Anesthesia

Chairman—Robert B Hammond White Plains
 Secretary—S LeRoy Sahler, 194 Culver Road, Rochester

Significant action by the Council is here presented for the information of the membership

Medical Care of Those on Relief

It was decided that contact be made with the Health and Welfare Departments in the effort to bring the fees paid, "reimbursable fees," into line with the fee schedule for Workmen's Compensation

Annual Meeting

A fourth day was considered desirable for the Annual Meeting and it was directed

that all activities, including scientific programs, continue into this additional day

Workmen's Compensation

The Industrial Commissioner has arranged that a hearing be held on his proposition for certain percentage reductions in promulgating for the State generally the fee schedule now in operation in the Metropolitan area. Dr Kaliski reported that he had requested postponement of this hearing until September and asked that a large representation from the State Society be prepared to attend in order to oppose any reductions. It was Dr Kaliski's information that delegations from the other groups concerned—insurance carriers and employers' associations—would number about fifty. The Council undertook to provide for appropriate representation.

4-H Club Examinations

At the suggestion of Dr Farmer, the Chairman of the former Standing Committee on Public Health and Medical Education, the Council went on record as in favor of the efforts of the 4-H Clubs to increase the health consciousness of the citizens of the State by means of competitions in the Counties and in the State generally between children, looking to the choice of the healthiest child in each County and the healthiest child in the State. To achieve this end, the Council requested the County Societies to assist by appointing from their membership physicians who would make examinations of competing children.

District Branch Meetings

These have been scheduled as follows

Sept	21	— Sixth District Branch at	Owego
	22	— Seventh " " "	Geneva
"	23	— Fifth " " "	Lowville
"	30	— Third " " "	Kingston
			Glens Falls
Oct	1-2	— Fourth " " "	New York City
"	5	— First " " "	Olean
"	7	— Eighth " " "	Garden City
Nov	17	— Second " " "	

Financial

A budget was drawn up and recommended to the Board of Trustees in the usual fashion. It was also recommended that the fiscal year and the dues year be made to coincide in such a way as to permit the Treasurer to complete his report in time

for the Annual Meeting. Instead of July 1 of one year to June 30 of the next year, the new arrangement would make the fiscal year begin on April 1 to extend until March 31 of the following year.

Noise Abatement

The Council considered a resolution passed by the Section on Neurology and Psychiatry at its meeting on May 26, 1937. This Section resolved that

Whereas, the Medical Society of the County of Monroe and the Academy of Medicine of Rochester has been cooperating with the Mayor's Committee on Noise Abatement, and

Whereas, it is recognized by the medical profession that unnecessary noises are a factor in the production and the exaggeration of disease states,

Be it Resolved, by the members of the Section on Neurology and Psychiatry that they go on record as approving the efforts of Noise Abatement Commissions throughout the State of New York, and cooperating with them in their efforts directed toward noise abatement.

It was felt by the Council that this matter is of such importance as to deserve further study and the Council Committee on Preventive Medicine was directed to bring in recommendations.

Reports by Delegates to Their County Societies

It was brought to the attention of the Council that there exists no common practice of reporting back to their parent County Societies by the Delegates who attended the Annual Meeting. In Tioga County, the Council was informed, such reports have been made for some time and are considered very useful by that County Society. The Council went on record as commending such procedure to the County Societies.

Future Meetings of the Council

Regular monthly meetings to be held in the Society's offices, 2 E 103 Street, at 10 00 A.M. will begin in September, continuing through on the second Thursday of each month until the next Annual Meeting. The September meeting will occur on the third Thursday, the sixteenth.

CHARLES H. GOODRICH, *President*
PETER IRVING, *Secretary*

DISTRICT BRANCH MEETINGS

Third District Branch

The program for the annual meeting of the Third District Branch to be held in the Governor Clinton Hotel, Kingston, September 30, is as follows

Daylight Saving Time

10 00-10 15—Address of Welcome—Fred H Viss, M.D., President, Ulster County Medical Society

10 15-11 15—"Malignancy as Seen by the General Practitioner"—Louis C. Kress, M.D., State Institute for the Study of Malignant Disease, Buffalo, and Arthur M. Dickinson, M.D. A discussion of the methods of diagnosing and treating cancer of the various parts of the body that may be employed by the general practitioner. The discussion will deal especially with the etiology and early symptoms of cancer of the breast, uterus, stomach, and rectum. The symptoms, pathological picture and treatment of Hodgkin's disease will be included.

11 15-12 00—"The Pathology of Vascular Disease"—Milton C. Winternitz, M.D., Yale University School of Medicine, New Haven, Conn. Dissection, injection and clearing as preliminary to sectioning and staining indicate that vascularity of the walls of blood vessels plays an important role in the genesis of arteriosclerosis. Hemorrhages of varying magnitude are common findings in the walls of arteries at many stages in the arteriosclerotic

process. The fate of this extravasated blood and the role it plays in subsequent changes, leads to a broad correlation of diseases of the blood vessels with other growth and reaction processes.

12 00—"Presenting Symptoms and Diagnosis of Renal Tumor"—Lantern slide demonstration—George F. Cahill, M.D.

1 00—Luncheon and introduction of guests

Afternoon Session

2 00-2 15—Business meeting

2 15-2 40—"Preventive Medicine"—Charles H. Goodrich, M.D., President of the Medical Society of the State of New York.

2 40-3 15—"How to Analyze a Case of Bright's Disease"—Benjamin I. Ashe, M.D. Pathology, as evidenced by the living patient, edema, blood pressure changes, renal function, uremia, anemia.

3 15-4 00—"Dialogue on the Use of Protamine Zinc Insulin and Other Diabetic Problems"—Howard F. Root, M.D., Boston, Mass., and Stephen H. Curtis, M.D. Comparison of the results obtained in using regular insulin and protamine zinc insulin, selection of either as best fitted to use in individual cases. Relationship of the individual's carbohydrate and metabolic deficiencies and the role these play in the choice and dosage of insulin. Dietetic problems and the relationship of insulin administration.

Fourth District Branch

The program for the annual meeting of the Fourth District Branch to be held at the Hotel Queensbury, Glens Falls, October 1 and 2, is as follows

OCTOBER 1, 2 30 P.M.

"The New Constitution and By-Laws of the Medical Society of the State of New York. Why the Changes and What We Should Gain Thereby"—Thomas H. Cunningham, M.D.

"The Future of the Albany Medical College"—Robert S. Cunningham, M.D.

"Treatment of Fractures of the Hip"—William D. Johnson, M.D.

7 00 P.M.

Dinner at Queensbury Hotel.
Address by Charles H. Goodrich, M.D., President of the Medical Society of the State of New York.

"The Art of Prestidigitation"—Gordon C. Peck, M.D.

OCTOBER 2, 9 30 A.M.

"The Use of Sulphanilamide in the Treat-

ment of Infections of Childhood"—Benjamin W. Carey, Jr., M.D. Boston, Mass. The results of the use of para-aminobenzenesulfonamide and its derivatives in the treatment of infections in infants and children caused by the B hemolytic streptococcus, the meningococcus, the gonococcus and the colon bacillus, will be presented. Included will be a discussion of the dosage, methods of administration and toxic reactions encountered in the use of the drugs.

"The Prevention of Heart Disease"—Paul Dudley White, M.D. Boston, Mass. The study and treatment of heart disease have now progressed to the point of intensive thought and work on preventive measures. It is already becoming evident that certain kinds of heart disease can be prevented and we are steadily accumulating clues that may help us eventually in the prevention of heart disease in the majority of young and middle-aged individuals.

"A survey of the Latest Thought in the Treatment of Cancer"—Frank E. Adair, M.D.

NOTE. On Friday afternoon there will be a bridge tea at the Glens Falls Country Club for the visiting ladies.

Fifth District Branch

The program for the annual meeting of the Fifth District Branch to be held in the Masonic Temple, Lowville, September 23, is as follows

10 00 A M—Standard Time

"The Problem of Simple Goiter"—John C McClintock, M D, and George E Beilby, M D

The factors leading to the development of simple goiter are reviewed. The symptoms presented by these young patients are recorded, leading to a discussion of the prognosis with a review of a series of cases observed. The most important problem relating to simple goiter is its treatment which should relieve the symptoms and prevent if possible future thyroid disease. Careful and conservative observation is the keynote of success in dealing with this type of goiter. Not a small part of the treatment is the prevention of goiter which is discussed with a review of the methods accepted at the present time.

"Importance of Early Diagnosis in Affections of the Hip"—Lantern slide demonstration—Charles H Bladwin, M D. The number of cripples resulting from pathological processes occurring in and about the hip still remains unnecessarily large. Only by early recognition of the fact that the hip is the seat of disease or malformation and the institution of appropriate treatment can this number be lessened. Early diagnosis is always possible, and, for the most part, not difficult. If good results are to be obtained the family doctor must be depended upon. While a small percentage of cases should be hospitalized over fairly long periods, the average case may be treated at home, provided home conditions are good. The significance of limp pain, limited joint motion should be well understood, as well as the fact that a joint may receive irreparable damage in

a very short period. Prognosis depends on the nature of the affection as well as on early diagnosis.

"Diagnosis, Treatment and End Results of Malignant Neoplasm of the Female Genital Tract"—John A. Kelly, M D

2 00 P M—Standard Time

Business meeting Election of officers

"Preventive Medicine"—Charles H Goodrich, M D, President of the Medical Society of the State of New York.

"The Management of Peripheral Vascular Diseases"—Herman E. Pearse, M D. During the last decade vascular disturbances of the extremities have received unusual attention resulting in a clearer conception of the etiology, diagnosis and treatment of arterial obstructions. Many of these advances have been made by the use of laboratory methods in the clinic, so that the student or practitioner is often bewildered by the multiplicity of tests, methods and apparatus employed. This is undesirable and unnecessary because with the simplification of these procedures it should be possible to obtain all essential data with ordinary equipment. Hence an effort will be made to evaluate the newer methods of estimating vascular deficiency in terms of every-day use. The subject will be considered using the classification of peripheral vascular disorders into those due to the arterial diseases that cause spasm, occlusion and a combination of both, as well as the effects of trauma, thrombosis, and embolism.

"The Management of Urinary Lithiasis"—Roscoe C. Borst, M D. The writer discusses the recently accepted etiological factors, the dietary regimes, urinary antiseptics, their values and dangers, and the need for intensive, co-operative study of these cases by the bacteriologist, internist, physiological chemist, and the urologist, The Jeans Test.

Sixth District Branch

The program for the annual meeting of the Sixth District Branch to be held in Owego, September 21, is as follows

Westminster House—Presbyterian Church

10 00 A M—Standard Time

"Treatment of Vesicle Neck Obstruction and Prostatism"—Elliott T Bush, M D

"Tumors and Other Diseases of the Spinal Cord Amenable to Surgery"—William P Van Wagenen, M D

"Diagnosis and Practical Measures in the Treatment of Anemia"—John S Lawrence, M D

Luncheon and introduction of guests, Green Lantern Country Club

2 00 P M, Standard Time

Business meeting and election of officers

"Preventive Medicine"—Charles H Goodrich, M D, President of the Medical Society of the State of New York.

"Some Newer Aspects of the Treatment of Peripheral Vascular Diseases"—Irving S Wright, M D

"Diagnosis and Management of Cutaneous Cancer"—Anton W Sohrweide, M D

Provision will be made for the entertainment of the ladies

Seventh District Branch

The Joint Annual Meeting of the Seventh District Branch of the Medical and Dental Societies of the State of New York, will be

held September 22, in the State Armory, Geneva. The program scheduled is as follows

Morning Session (Standard Time)

10 00-10 30—"Observations on Obesity" by David A. Haller, M.D., Rochester. Obesity is largely untreated and is allowed to exist as a physical handicap and predisposing factor to chronic disease states. Glandular dystrophies associated with obesity may be relieved in part by diet, but obesity can rarely be relieved by administration of glandular products and these may be unsafe.

Discussion by Byron D. Bowen, M.D.

10 45-11 15—"Pneumonia Control" by Edward S. Rogers, M.D.

Discussion by Edward G. Whipple, M.D.

11 30-12 00—"Newer Aspects of the Etiology of Cancer" by Burton T. Simpson, M.D. In the last five years great advances have been made in the etiology of cancer. We are now able to produce both carcinoma and sarcoma by specific synthetic chemicals. A very strong carcinogenic agent can now be produced from bile acids. It has been shown that the sex hormones play an important part in carcinoma of the breast. Discussion by L. C. Kress, M.D.

12 15-12 55—Exhibit of specimens from the State Institute for the Study of Malignant Disease. Dr. Morton L. Levin.

1 00—Luncheon and introduction of guests—Hotel Seneca.

Afternoon Session

2 00—Business meeting and election of officers.

2 15—"Medico-Dental Cooperation in Preventive Medicine" by Charles H. Goodrich, M.D., President of the State Medical Society.

"Medico-Dental Cooperation in Clinical Medicine" by Edwin I. Harrington, D.D.S., President of the Dental Society of the State of New York.

"Medico-Dental Cooperation in Education" by Theodor Blum, D.D.S., M.D. Medico-Dental cooperation must be established for one purpose, namely, the improvement of health service. To achieve the above the physician must familiarize himself with the dental problem and the dentist with the medical, and meet each other on an equal basis in bordering fields. Criticizing either profession to the public increases the difficulty of our task.

For the Ladies

Luncheon for the ladies will be served at Belhurst. It will facilitate arrangements if those planning to attend will notify the Chairman, Mrs. Andrew D. Hubbs, 6 Delancey Drive, Geneva, by post-card or letter of their intention.

Boating, golf, and cards will be provided. Ladies are requested to register at the State Armory.

Dr. Burton T. Simpson, Director of the State Institute for the Study of Malignant Disease at Buffalo, has arranged an educational exhibit for the general public which will be open from 2 00 P.M. to 4 00 P.M. at the State Armory, Geneva. This exhibit will be in charge of Dr. Morton L. Levin of the State Institute staff. There will be no charge for admission and the public is urged to attend.

At 5 15 P.M. there will be an informal gathering of the ladies and members of the District Branch and guests at Belhurst, on Lochland Road.

POLLEN FILTERED OUT BY AIR CONDITIONING

Victims of hay fever and other respiratory affects are assured of a "high degree of benefit" from air conditioning today, as a result of a series of pollen tests by Professor F. H. Hodgson, department of allergy botanist at Roosevelt Hospital, New York City.

Professor Hodgson conducted his tests in a room where the air was heavily saturated with dust and pollen. The unit was a summer portable room cooler without special attachments.

Actual results in one of the main tests in a "room to be used by an allergic patient," Professor Hodgson said, showed the pollen count reduced in 10½ hours, from 1050 to 2 per square centimeter.

At regular intervals the amount of pol-

len remaining in the room was carefully counted on an exposed slide. Professor Hodgson reported. Four and a half hours after the experiment was begun, the pollen count had been reduced from 1050 to 70, three hours later, the count had dropped to five, and, ten and a half hours from the start of the experiment, the count was only two.

Summarizing the results of his various pollen tests, Professor Hodgson reported.

"From many experiments, it would seem that the efficiency of the air conditioning device is sufficiently good to assure a high degree of benefit to a patient suffering from exposure to air containing irritants, especially house dust and natural pollens."

A healthy man must feel unhappy when he listens to the medical ballyhoo on the radio and realizes how easily, surely and

pleasantly he could be cured of many interesting ailments, if he only had them—
Ills Med Jour

PNEUMONIA CONTROL PROGRAM

Post-Graduate Educational Institutes in Pneumonia for the General Practitioner

The New York State Medical Society in collaboration with the Bureau of Pneumonia Control of the New York State Department of Health and in cooperation with some of the large medical school hospitals of the State is sponsoring a series of one-day institutes on "The Diagnosis and Treatment of Pneumonia" with special emphasis on serum therapy. These institutes will be held in the five academic centers of the State Albany, Buffalo, New York City, Rochester, and Syracuse, and will accommodate physicians in the counties surrounding these cities. The educational facilities of these institutes will be extended to the general practitioner who is desirous of learning more in detail about the recent advances in the diagnosis and treatment of pneumonia and who is anxious to familiarize himself with the exact technic of serum therapy.

Each institute will accommodate fifty physicians in the counties surrounding the location of the institute. The number of physicians accepted from each county will depend on the medical population of that county. Applications will be accepted in the order in which they are received, with the exception that, an attempt will be made to distribute the quota evenly throughout the individual county whenever possible. It is therefore necessary that those who are interested send in their applications early, before the quota of their county is exhausted.

No fee will be charged to those attending the institutes. The New York State Department of Health will reimburse traveling and maintenance expenses of those attending up to a maximum limit of \$20 per physician.

The institutes will consist of the following

- 1 Talks by outstanding authorities on pneumonia, i.e. Doctors Bullowa, Cecil or Cole, on various aspects of the diagnosis and treatment of the disease with special reference to serum therapy

- 2 Small group demonstrations on blood donors of the actual technic used in the administration of serum, the taking of blood cultures and the performance of sensitivity tests

- 3 Lecture and demonstration on the use of oxygen

- 4 Informal discussions with the Speakers and other authoritative physicians regarding individual problems

- 5 Ward rounds by the Speakers on clinical material if cases are available at the time and place of the Institute

- 6 Sound moving-pictures illustrative of the technical aspects of serum treatment and nursing care in the home will also be shown.

The final schedule of the institutes and the place of meeting of each will be published in the next issue of the JOURNAL. A tentative schedule of the institutes with the counties served by each follows

Syracuse Institute, October 12

St Lawrence	Lewis	Onondaga	Broome
Herkimer	Jefferson	Cortland	Cayuga
Oneida	Oswego	Chenango	Madison

Rochester Institute, October 19

Wayne	Seneca	Schuyler	Tompkins
Tioga	Steuben	Ontario	Monroe
Livingston	Alleghany	Chemung	Yates

Buffalo Institute, October 25

Orleans	Genesee	Cattaraugus	Niagara
Chautauqua	Erie	Wyoming	

Albany Institute, November 9

Columbia	Albany	Warren
Schoharie	Saratoga	Hamilton
Schenectady	Washington	Franklin
Montgomery	Clinton	Otsego
Essex	Delaware	Fulton
Greene	Rensselaer	

New York City Institute, November 23

Suffolk	Nassau	Westchester
Rockland	Orange	Dutchess
Putnam	Ulster	Sullivan

Applications are to be sent to Dr. Thomas P. Farmer, Chairman of the Council Committee on Medical Education of the New York State Medical Society, 608 E. Genesee St., Syracuse.

Dr. J. B. Conant was elected president of the Northeastern Doctor's Golf Association at a meeting on July 1 at the Antlers Club in Amsterdam. Dr. Conant has been active in the organization for many years.

A tribute was paid to Dr. Andrew McFarland who for about thirty years was prominent in the work of the association. The vice presidents are Dr. O. A. Brenenstuhel and Dr. S. H. Curtis.

Economics

Working for Nothing and Boarding One's Self

FLOYD BURROWS, M D, *Syracuse*

There is a strange psychology rampant in the public mind about medical fees and their payment.

In the first place most individuals erroneously regard them as usually exorbitant

In the second place, as a class they look upon doctors as wealthy mortals. Without any more analytical struggle than a bumblebee exerts when he lands on a clover blossom to gobble a mouthful of nectar they unconsciously assume that ninety-nine pennies out of every dollar a physician collects are rushed into a savings bank.

In the third place the average person who owes a bill ranging from one dollar to a hundred often negligently coasts along dodging its payment on the theory it is only a small amount, someone else is paying, so he should worry! If he himself had scores of such claims hanging fire and his expenses had to be met in cash each month like an M D's have to be, indeed he would worry—and how!—especially if in addition his neglected wife was pursuing him vigorously for warm silk hosiery or a couple of comfortable satin night gowns

Another amazing psychological quirk is the attitude so many hold that doctors should do a huge amount of work for nothing. Relatives of a doctor's family are deliberate spongers in this respect. Doctor's employees are another group who expect service without paying for it. Trained nurses he knows and acquaintances who work in hospitals are others who are transgressors. Practically all the clergy are distinguished offenders. Many patients who have destitute hangers-on or are interested remotely in destitute people expect their doctor if called upon to render service free of charge in such cases and grin like a Cheshire cat at the Christian opportunity.

Why should an employee of a doctor expect free medical service when an employee of a meat market has to pay for his steaks?

Why should a cousin, a sister-in-law, or an uncle expect a doctor-relative to take

care of their broken leg or dislocated shoulder—especially if they are financially more competent than he is—when another relation closer connected charges them well for repairing a clutch or replacing a crankshaft on their automobile?

Why should a clergyman who draws a fat salary for welding and hammering sermons on his pulpit-anvil for a flock of alert sinners expect an M D to run around in the night for nothing if his baby has the croup, when a prosperous merchant who is a sleepy member of his aristocratic congregation gets paid for each pair of the kid's shoes?

Why should a patient—who prides himself he is a good one just because he promptly pays his bills—run to the phone, summon his doctor for service to a pauper in the neighborhood and expect him as a favor to shoulder the situation free gratis? Why doesn't he call up a banker with whom he has a few hundred on deposit or a broker from whom he has purchased several shares of questionable stock and as boldly ask for a gratuitous five dollars to pay a medical fee? Or why doesn't he pay it himself?

Doctors are beginning to require a pertinent answer to these questions, even though lay persons regard such queries as highly impertinent. I think I know the answer—or a partial answer. An example or two will serve to illustrate it.

An anxious husband brings his wife to the physician because of a small bunch in her breast. The physician painstakingly examines the organ, makes a responsible diagnosis of cancer, and seriously advises an immediate operation for removal of the gland. The examining, diagnosing, and advising consume twenty minutes. The rapidity of the procedure is made possible by the expert knowledge which the doctor has painfully, laboriously acquired during an exacting period of years. This fact however is obscured behind the screen of immediate visibility, so when a fee of twenty-five dollars is asked the twain think they have been held up by a Dillinger, M D

Applications are to be sent to Dr. Thomas P. Farmer, Chairman of the Council Committee on Medical Education of the New York State Medical Society, 608 E. Genesee St., Syracuse.

Dr. J. B. Conant was elected president of the Northeastern Doctor's Golf Association at a meeting on July 1 at the Antlers Club in Amsterdam. Dr. Conant has been active in the organization for many years.

A tribute was paid to Dr. Andrew McFarland who for about thirty years was prominent in the work of the association. The vice presidents are Dr. O. A. Brenenstuhl and Dr. S. H. Curtis.

lic cries petulantly for such service. If refused, the public goes into a tantrum with a display of as little judgment, as the child.

Charity is a wonderful blessing to extend to those who are actually in need of it. I am not decrying a discriminating use of it, or advocating the transformation of one's cardiac muscle into a heart of flint. But personally I want to know my contribution is not wasted or bestowed upon unworthy people who can afford to pay for my services but who try to mulct me as an easy mark.

Recently a patient visited my office with her son who had contracted scabies. During the call I casually inquired, "When are you going to have little Abie's tonsils out?" The mother smiled and with visible embarrassment replied, "I have had them out already. I took him to the free dispensary and they did it for nothing."

Her husband is a railroad engineer earning a hundred-and-eighty dollars a month!

When I remonstrated because she deliberately had played a reprehensible trick on my profession she nonchalantly shrugged her shoulders remarking, "One of my neighbors took her boy there and told me about it. If I can get something for nothing, what's the harm?"

The harm is that thousands—yes, tens of thousands—of analogous examples and worse are wilfully, maliciously, perpetrated on lackadaisical doctors in the United States every year and nothing radical is devised to eliminate the evil. It is indeed a poor business system which permits it to exist.

Not so far distant, time was, when a doctor could visit the sick on foot, or travel to them by inexpensive horse locomotion. But with the advent of the automobile the days of the "gay nineties" and before vanished like a pleasant, transitory dream. Expenses then were practically nil compared with today. The overhead was a mere item and a physician if so disposed could utilize spare time in an eleemosynary way without serious drain on his pocketbook. Everything jogged at a slow and easy but safe gait. The currents of life ran less turbulently in that halcyon era.

But now autos have speeded the pace from less than ten miles an hour to sixty plus. Expenses have run swiftly ahead in corresponding proportion. The cost of practicing medicine in 1937 makes it well-nigh prohibitive to care for sick people without

pay except in a very limited way. One might as well maintain a clothier generously should hand a suit to every one in tatters who begs necessary raiment, or a shoe merchant gratuitously furnish foot gear to those who unfortunately are run down at the heel, as to demand medical attention from physicians free of charge.

Doctoring is the only business, except racketeering, where an utter stranger feels he can skip glibly in, grab something and not say, "I-yes-or-no" about paying for it. Even the churches pass a collection plate. The "butcher, the baker and the candlestick maker" have some well thought out ground rules as to how their games shall be played. Why also should not medical men have some business sense in marketing their brains, their hard won experience and often a precious part of their physical self?

If a man unknown to the proprietor of a meat market excitedly dashed in and exclaimed, "My God, mister, my family are starving. Give me ten pounds of your best roast beef and a couple of thick porter-houses, but I can't pay you!" the butcher, either would tell him to go where it is so reputed hot meat cooks in a jiffy, or else direct him to some welfare organization where his needs could be attested to, provided for, and the expense distributed equitably.

But how about a doctor? If it's ten below and the world as bleak and wind swept as a Greenland ice field, he is expected to jump blithely out of bed every time the phone rings or some dead beat sneaks up and pushes his night bell, all a-quiver with eagerness to dash in a humanitarian fashion to some destitute bedside. He is expected to enjoy the tune he whistles while waiting for his pay. He also must take care of his own chilblains.

It is estimated that there are a very large number of physicians in the United States. I have forgotten the exact statistics, but as Mark Twain says, "It is no matter, it is near enough."

Why should all these doctors annually year in, year out, give millions and millions worth of expense-exacting service for nothing? Why should they take care of all the indigent free of charge? Why should not the cost be distributed by taxation *pro rata* on the population at large and not all fall on the shoulders of one class? Why should they be good fellows like this and

A gay married blade—or a single one for that matter—steps out for a bat some night when his arch supporters are not as efficient as usual. A week later he nervously dashes into a doctor's office because a strange discharge has appeared in an organ which he doesn't ordinarily expose freely except on such hilarious occasions.

The doctor places a bit of offending pus on a slide, peeks at it with a microscope and informs the wild nighthawk—somewhat to his discomfiture—he has contracted that derogatory badge of he-manhood—that disease which frequently but mistakingly is considered “no worse than a cold in the head”—filthy, despicable gonorrhea. He makes a charge of ten dollars and the high stepper squeals like a rat—which many times he is. A week before he would have blown the same amount for a couple of magnums of champagne with an abandon only equalled by the ruthlessness he exhibited when he negligently left the deserted wife or sweetheart at home.

The trouble is, such individuals and many others without enough thoughtful reflection to agitate a dozen brain cells think a doctor puts into his efforts only his time. Furthermore they imagine doctors love their work like baseball players do their game and are as eager to dash in response to a sick call as a Babe Ruth was to bat another home run. They look upon medical work as if it were a musical inspiration and assume a doctor is as crazy to practice it as an indefatigable saxophone player is to toot such an infernal instrument morning, noon, and night—night especially.

When people go shopping and purchase various commodities they have something visible, something tangible, to represent their expenditures. But when people go medical shopping they do not put packages galore—which contain the proportionate cost of a doctor's education, his investment to establish himself on an earning basis ample to make both ends meet, his rent, secretarial hire, telephones, drugs, and the thousand-and-one other expenses which eat up his income like an elephant eats hay—into a market basket as they do parcels in a master food store, or have deliveries of diagnoses wrapped like merchandise arrive at home the next day.

I used to care for an old codger who was as close as the cutis is to the cuticle. He had never been ill until the last few months

of his life. I motored five rough miles to pay him a visit and charged him three dollars for the call. Every time he paid he howled as though I had drawn a molar.

“You doctors,” he would bitterly exclaim, “are highway robbers. No wonder you get rich. If I could make money as easy as you do I'd think I was working a gold mine.”

No amount of friendly argument could convince him he might be considerably in error. He could not understand how it actually cost me in overhead expense approximately one dollar to earn three dollars. He finally died believing a professional gangster had cared for him in his last illness. No doubt he is explaining to the angels how he was hurried on his celestial voyage by a medical pirate. He probably will celebrate eternally his escape to a heavenly region where it is reputed there are no doctors.

When such crass ignorance is encountered all one can do is stand by his weapons like an artillery gunner and fire his price straight from the shoulder.

Another thing which often makes doctors' bills assume outrageous proportions to the billed is the fact very few people keep an account themselves of the number of visits he makes at their homes or the number of times they, or members of their family, call at his office. When his statement—usually not itemized—finally arrives some gloomy morning they are disturbingly amazed at its size and—subsequent to an exhilarating household powwow—a considerable reduction is demanded forthwith in no uncertain terms.

I think the explanation I have given accounts in a large measure for the reason doctors have to continually adjust bills, and offer discounts to amicably settle many of them—thus being compelled to do a large amount of work which is unpaid for.

Trying to live up to a silly, exalted reputation for charitableness is another prime factor which enters into the complex problem of working for others without remuneration. From time immemorial doctors have been accustomed to donate their services lavishly and freely, often rushing forward in an enthusiastically zealous manner lest they be deemed inhumane, until now in this depression debacle the public has been taught to expect such voluntary benefactions in an exaggerated fashion. Like an infant who never has been curbed in its desires the pub-

Preventive Medicine

Practical Aspects of Public Mental Hygiene

B LIBER, M D, Dr P H, F A P H A, *New York City*

Lecturer on Mental Hygiene, New York Polyclinic Medical School and Hospital

Knowing that all public health work, including public mental hygiene, depends so much on prevailing social and economic conditions, I could easily describe an ideal state in which mental health work would be unhampered and at a high level, but that would be impractical and not in keeping with present circumstances and with the solving of our problems at hand. When I was asked to speak before this meeting I was told that we were concerned with the necessity of incorporating definite practices through existing health agencies for the prevention of mental disease on a large scale.

Interested in mental hygiene, which, even in therapy, consists more of prevention than of real treatment, I have departed somewhat from psychiatry, which is inclined to deal more with the developed psychotic cases. Both from my clinical work here and abroad and from my own private practice I have learned the need of a public and social approach in all mental health matters. We cannot separate the individual, his mind, his adjustment, or lack of adjustment, from his environment, past and present. It is impossible, therefore, and entirely useless to attempt to prevent mental diseases from the public or personal standpoint without taking into consideration the station in life of a given person or a group, the family relationship, the upbringing, the occupation, the intellect and education, the race and nationality, the near and remote past. None of us has fallen from the moon, each one of us is a tiny ring in a long chain, and our reciprocal interdependence is infinite.

That is why I believe that the theoretical, generality or pioneering or infancy, or groping, trend of mental health must give way to a more mature period and that it is about time that the health agencies study and understand mental hygiene from a public viewpoint and take over its problems. They have been ignored too long. So far

and on the whole public health men have failed to see their importance. Indeed these problems are just as momentous as those related to communicable diseases. It would certainly not be an exaggeration to maintain that mental diseases are sometimes even more contagious than the somatic ones.

In this country the mental hygiene movement was founded, at the dawn of this century, by a splendid man, who, after being hospitalized as a psychopath and having suffered much from mistreatment in institutions, managed to be cured and fight his way out of the insane asylum. He was helped in his work by psychiatrists. It was natural, then, that the mental hygiene movement should from its inception take the form of a struggle for the improvement of the hospitals for the insane and of the condition and treatment of the insane. He had had a great forerunner, Pinel, who, 100 years before, had taken, so to say, the part of the misunderstood and persecuted and tortured mental patient and, at the risk of being ridiculed, had given to the world a new idea about insanity.

The modern Frenchman, Dr Toulouse, who started his work at about the same time as Clifford Beers here, and who is still active along the same lines in Paris, has had another conception of mental hygiene, which he properly calls mental prophylaxy, that is, prevention of mental diseases or rather conservation of mental health.

There is a need for a re-definition of mental hygiene. It is not psychiatry proper and should not be regarded as such. It is not therapy, but prevention of mental diseases or, like all hygiene, treatment before or almost before the disease appears or develops. It has nothing to do with hospitals for the insane or with the manner in which the psychopaths are treated there. It is not a fight for the amelioration of such institutions, although this may be a necessary work also.

Mental hygiene is a part of general hygiene and public mental hygiene is a public

Reproduced by permission of the *American Journal of Public Health*, July 1937

Read at a Special Session of the American Public Health Association at the Sixty-Fifth Annual Meeting in New Orleans, La., October 20, 1936

in addition be expected to subscribe generously to every charity, church, hospital, bazaar, community chest, and what not? Why, after they have done all this, should they be obliged also to pay their proportionate taxation in support of every eleemosynary affair in our governmental set-up?

Why I ask you? Well, I'll tell you in plain words—*doctors head the sucker list!*

Personally I am disgusted with this asinine status. The medical profession needs more vocal dynamite and less verbal pussyfooting. It must breed more financial hounds that can follow a strong business scent and fewer highly trained poodles which would not get the smell of a dollar if they ran sniffing through a mint. It is high time to commence doing something constructive to abolish this absurd situation.

As a business individual I insist on paying everyone their price for what they do for me, whether it is tightening a nut on my car, brushing off my clothing, or giving me a road map, showing the straight and narrow pathway to heaven. I do not let some cheap clodhopper do a fifty-cent job, and say "That's all right, Doc, no charge", and then some day, do a ten dollar consultation for him, and have him expect me to make the same reply, I pay for what I get, and charge for what I give, if it is only headache tablets.

When I am employed by the clergy—Jewish, Catholic or Protestant—I render the same bill as to a sinner. When December 25th comes, and I send them a check, with "Merry Christmas" attached, everything is sweet and lovely between us, by the happy new year. This cuts down their night work surprisingly, and does away with two calls, when only one is needed. They never fully know, I might break my arm at holiday time.

I am not such a Shylock. I charge my wife or her mother for professional services. But uncles, cousins and "inlaws" bring a check or a bankroll when they come to my drug emporium to consume my time and carry away my miraculous remedies. I do my share of charitable work willingly and always have, but I am not doing it for those who can pay for it, leaving those who need it—but who cannot pay—to suffer.

Maybe I should flay myself and wear sackcloth and ashes. But I always have believed conscientiously a medical servant was

worthy of his hire. When I have moved a constipated person's bowels successfully, or accomplished some other laudable professional stunt, if asked to state a fee for my accomplishment, I never have turned white around the gills, given way to emotional tremors, or dampened my BVD's with the sweat of diffident meekness and blushing humility. Perhaps my system is not altruistic enough, or embued sufficiently with that old, sanctimonious, delusion of acquiring virtue and piety by working for nothing and boarding myself.

I always have liked overstuffed furniture, Simmons' beds, occasional drinks of Scotch "likker", and other sinful luxuries, too much, I fear, to defer my rewards until—like a glorified saint—I volplane with extended wings into paradise. Neither do I revel in having financial worries chase me like little devils through every tour of dreamland. I attempt—often a limited excursion because someone gets the belly ache while I am trying to snore my way peacefully on the trip.

I never have held ambitious desires to become a Croesus. But somehow I always have had the notion tucked away in my cranium that it was a legitimate aspiration to corral enough money from my practice to educate my youngsters, pay my life insurance premiums, buy my wife a new fur coat at least once during her troublous struggle as a doctor's mate, keep a roof over my humble head in such condition I would not have to raise an umbrella at mealtime, and run an auto which would go at least twenty miles an hour and bring me home safely without a tow car, when I journey out into the wide open spaces to hear the inspiring songs of the birds, smell the fragrant perfume of the wild flowers, and acquire a load of renewed courage to bring to my sick.

Perhaps my philosophy is all wet and surcharged with selfishness. Be that as it may, I always have fought vigorously for these privileges and perquisites, and always will so long as good red corpuscles continue to scam through my 130 blood pressure system, and I pursue the exhilarating sport of painting sick clouds with medical sunshine.

That is why, in behalf of my down-trodden brethren, I struggle to blaze a trail for them through the unremunerative realm of physic.

amined, and advised. As much as possible those originating from families in which insanity or feeble-mindedness prevails would be discouraged from mating with those born into similarly handicapped families—both in their own interest and that of the community, it would be explained to them. The existence of such bureaus would also have a salutary and educative effect upon the people at large. At the same time, cases of gonorrhea, syphilis, and tuberculosis would be discovered and treated in marriage candidates. Other bad and evident mismating might be avoided. The effect of such bureaus would amount to a sort of modified eugenics. They would also give birth control instructions in appropriate cases and where that would be absolutely necessary in order to prevent possible mental misfits.

Several years ago I observed the work of the highly efficient and free Heiratsberatungsstellen of Vienna founded by the late Professor Tandler and now all but wrecked. It was a worthwhile work that we should imitate and perfect.

As the various school authorities are rather reluctant to teach the necessary sexual facts to adolescents, public health agencies should undertake this work and open classes for young people where such instruction would be given. Dispelling the common fears and anxieties which are due to ignorance and misinformation, and lead to mental maladjustment and disorders, should be one of the greatest duties and one of the most useful functions of the health authorities. It would not only prevent mental troubles to a large extent, but it would prevent a good deal the spread of venereal diseases which are among the causes of mental disorders. It would also contribute toward a better life with fewer conflicts between married couples—and consequently again toward a diminution of mental disease.

All health departments have, sometimes on paper only sections on industrial hygiene. They should not only become generally more efficient than they have been in the past, but should be interested in the mental aspects of the workers as well. Public health agencies should enlighten the em-

ployers, large and small, that it is to their own advantage that the workers be clear-minded, alert, and calm, in order to avoid accidents, to produce more and do better quality work. That is, of course, connected with the avoidance of overwork, with the distribution of the work so that the number of the unemployed be diminished, with more time for leisure for those employed, with improving working conditions all around. Physical over-fatigue goes hand in hand with mental over-fatigue, and economic insecurity is one of the frequent causes, or predisposing causes, of psychosis.

On the other hand, public health agencies should also keep in contact with the trade unions and gain their cooperation so that some mental hygiene teaching might be possible through them in relation to industrial conditions.

Although alcoholism has its roots in social life, an intensive educational campaign against it should be inaugurated and waged unceasingly, as alcohol is one of the purveyors of mental diseases. This is easier to do now than it was during the prohibition years when it might have been suspected as of political or selfish significance.

Educational instructions and campaigns should not be of the "Don't Spit on the Floor" type or in the form of an order to be obeyed blindly. No one cooperates with such orders, because they are not convincing. Reasons must be given and the interest of the people, nay, even their enthusiasm must be aroused.

Mental hygiene should penetrate all our public health work. The more of mental disease we prevent the greater our help to humanity.

Let us get rid of as much as we can of the blighting, running mind troubles so disseminated that there is hardly a family entirely devoid of them. They make our people miserable, helpless, and unhappy and prepare further mental decay for the next generations. Let us get as close as possible to their causes. Let us free society from their strangle-hold and allow it to think more normally and rationally and work its way toward a greater happiness.

At the annual meeting of the New York State Association of School Physicians at Saratoga Springs, the following officers were elected:

President, Dr. Gilbert D. Forbes of Ken-
Vice-President, Dr. Dean F. Smiley

of Ithaca, Secretary-Treasurer, Dr. Marion Shepard of Batavia, Members of Executive Committee, Dr. Richard Weiser of Kenmore and Dr. C. A. Greene of Olean. Dr. Forbes presented a paper on "Problems of School Health Service."

health work—in the same sense as general personal hygiene is not private medicine and public health is not hospital treatment.

Mental health or the prevention of mental disease is closer to general public health than to psychiatry and medicine, although it is helped by both. And no public health work is complete or rounded out if mental hygiene, understood in a new fashion, is disregarded and excluded.

What, then, can public and official health agencies do for the prevention of mental diseases? Very much—and large and heavy programs might be detailed. But here I only wish to indicate as briefly and sketchily as possible a few of the feasible works as instances of what health authorities might undertake. These examples are meant to stimulate further practical suggestions by other workers.

To begin with, it is necessary to be informed about the worthwhileness of mental hygiene. Without being deeply convinced about its importance nothing can be done or it would be done half-heartedly. Then we must become interested in what I call the *transition cases*, those between mental health and mental disease, where prevention is still possible. As there is no definite boundary between health and disease of the mind, the cases of people who have begun to be unadjusted are to be found everywhere. They are extremely abundant and many are amenable to improvement if approached in the right manner and about 50 per cent of them, I claim from past experience with them, are curable. This is a broad and beautiful and fertile field, of much greater significance than that of the advanced cases. It has been comparatively neglected because it has been in the care of psychiatrists who are the greatest of medical men, but who usually are not health minded, who do not have the public health point of view, and are less interested in the transition cases than in the advanced ones.

I would advocate, therefore, preventive mental centers for adults conducted by health departments. I purposely would not call them clinics because they would really not correspond to what is commonly known by that word. They should be in the hands of special, or a novel type of, psychiatrists, who would be willing to work in a new spirit and with a new vision, that of prevention and that of having in mind the place of the individual in his group and in society. The function would create the organ. Naturally, they would have to be sympathetic and entirely absorbed in the study of these cases and their environment.

Of course, these centers would have to be connected with other public agencies whose object it is to solve or settle various individual problems, like courts, schools, parents' associations, trade unions, etc.

As child upbringing, sexual problems in all ages, but particularly in adolescence and youth, marital conflicts, industrial and economic difficulties, social frustrations contribute enormously to mental maladjustment or constitute its worst causes, every public health agency should turn its attention to these matters.

There should be a mental hygienist in each elementary or secondary public school of some appreciable size, one for a few smaller schools and several mental hygienists employed in each of the larger schools.

All pupils should be examined mentally once during their entrance year, reexamined if abnormalities are discovered, and a record kept about the findings. Irregularities should be discussed with the parents and the teachers. Behavior problems should be solved—or an attempt to solve them made—in cooperation with the parents, who would be instructed to report them. Very often it is their mistakes rather than those of the child that must be corrected and it is they who must be educated. Similar work is being done even now here and there, but insufficiently and not systematically.

The professional teachers' colleges should pay more attention to the study of child psychology and children's mental health. Health departments might be influential along such lines.

The child guidance clinics which were opened some years ago and functioned rather successfully in many places have been partly abandoned and partly shorn of their efficiency in the lean years. They should be revived, improved, and multiplied.

Easy courses in child upbringing for parents and future parents should be opened, preferably in public school buildings—always with a view of teaching possible mental disturbances and how to avoid conflicts which may lead to maladjustment.

Free marital consultation bureaus should be founded by health departments and all populated centers dotted with them. They should not be compulsory and should work in a rather friendly, sympathetic, and confidential way, trying to deal with the problems of young men and women who are willing to come for advice before marriage. These young people would be questioned, ex-

Medical News

Broome County

DR. CHARLES H. COLE, Superintendent and Medical Director of the Broome County Tuberculosis Hospital at Chenango Bridge, retires on Oct. 1 after sixteen years continuous service. Dr. Cole will reside in Binghamton.

TWO WINDSOR DOCTORS, Austin J. Stillson and William C. Armstrong, were honored by the Broome County Medical Society in August, at the opening of the centennial celebration of the founding of the Windsor township school. Scrolls which began as follows: "The people of Windsor township, with great affection and gratitude, tender this scroll to you as an expression of their sincere appreciation for your years of professional labor in their behalf," were presented to the two doctors by Dr. Samuel Allerton, president of the county association. Dr. Stillson has served thirty-six years and Dr. Armstrong, thirty-four years in Windsor.

Cayuga County

DR. FRANK L. DE FURIO has been appointed coroner of Cayuga County, to serve until Dec. 31, filling the vacancy caused by the death of Dr. Alfred F. Hodgman. A coroner will be elected in November and will take office January 1, 1938. Dr. De Furio will be the choice of Democrats for the office, while Dr. Raymond C. Almy has been approved as the Republican candidate.

Chemung County

THE ANNUAL OUTING of the Chemung County Medical Society was held at the Cold Brook Club on Aug. 26. A sports program included softball and quoits. Dinner was served at 6:30. Dr. Arthur W. Booth and Dr. Robert J. Lawler were chairmen. Physicians from adjoining counties were invited.

Dr. John F. Lynch is president and Dr. F. S. Hassett secretary of the Society which last winter celebrated its 100th anniversary.

Franklin County

DR. H. BEATTIE BROWN, former president of the Westchester County Medical Society, died on Aug. 13 at Saranac Lake, where he had practiced as an ear, nose,

and throat specialist for nearly twenty years. He was seventy-four. Dr. Brown practiced in Yonkers from 1890, when he was graduated from the College of Physicians and Surgeons, until 1897. He was associated with Dr. J. F. McLernan in New York until he went to Saranac in 1917. He belonged to many medical societies and was a member of the Medical Advisory Board during the World War.

Greene County

DR. B. W. GIFFORD addressed the members of the Greene County Medical Society in Haines Falls on July 20. Dr. Gifford is president of the third district branch of the New York State Medical Society.

Herkimer County

DR. FRED MORGAN BARNEY, who served in the United States Army as a medical officer in the Spanish War, the Philippine Insurrection, the Boxer Rebellion in China and the World War, died of a heart attack on Aug. 17. He was seventy-four years old and retired six years ago with the rank of captain in the Army Medical Corps.

Kings County

DR. THOMAS A. MCGOLDRICK, president of the Kings County Medical Society, has expressed complete accord with Magistrate Charles Solomon's action in suspending the driver's license of a man undergoing insulin treatment for diabetes.

Upholding the jurist's remarks from the bench that autoists suffering from "insulin shock" are potential killers, Dr. McGoldrick added the suggestion that the Motor Vehicle Bureau should submit all license applicants to thorough physical examinations instead of mere eyesight tests.

With dozens of his colleagues in Brooklyn who have told the press that the dangers are equally as great from those drivers afflicted with other ailments such as heart disease, paresis, advanced stages of tuberculosis, Dr. McGoldrick said he considered it wise to withhold licenses from all types suffering from ailments marked by sudden collapse, fainting spells and violent attacks.

Magistrate Solomon said he was elated by Dr. McGoldrick's remarks "especially since his position as Police Department surgeon gives added weight to this physician's statement."

Public Health News

Laboratory Aids in the Diagnosis of Infectious Mononucleosis

Infectious mononucleosis occurs chiefly as a sporadic disease of young adults, epidemics are rare. Glandular fever is a similar but probably different disease affecting children, epidemic outbreaks are not infrequent. Typical cases of infectious mononucleosis are characterized by fever, malaise, weakness, vomiting or nausea, enlarged and tender cervical or other groups of lymph nodes. Occasionally lymphadenitis is not observed. Sore throat and abdominal pain frequently occur. A diagnosis is established by the symptoms, a relative and absolute increase of large mononuclear cells in the blood—many of which are probably abnormal lymphocytes—and the demonstration of agglutinative properties for sheep red blood cells in the serum of the patient. Since the etiology of the disease is unknown, bacteriological studies are of no assistance except to exclude other infections. Although the acute attack is usually short, convalescence may be prolonged, in some cases extending over a period of several months. In its early stages the disease may be difficult to distinguish from acute lymphatic leukemia, but in the latter the patient's serum does not contain agglutinins for sheep red blood cells. The prognosis is always good.

Laboratory Findings

I Blood Count The blood picture is very

characteristic but not absolutely specific. Usually the total white blood cell count is between 12,000 and 20,000, occasionally there is a leukopenia, more than 50 per cent of the white blood cells are lymphocytes, many of which are of a type not normally found in the peripheral blood.

II Serological Test The blood of most patients with infectious mononucleosis agglutinates sheep red blood cells. From 5 to 10 cc of blood should be collected for the test. As is true in other diseases, these serological properties may not be demonstrated until a week or more after onset of symptoms. Also, the titer of the reaction has been found to diminish rapidly following recovery. In a consideration of the significance of agglutinative properties for sheep red blood cells, it should be borne in mind that blood of patients who have been injected with horse serum or certain other types of protein may also agglutinate sheep erythrocytes. The serum from children with glandular fever usually does not contain agglutinins for sheep red blood cells.

Although the incidence of infectious mononucleosis is relatively low in New York State, the disease is evidently more prevalent than is generally appreciated.—Leaflet issued by The New York State Association of Public Health Laboratories, May 1937.

Maternity Care Survey of Rural Relief Cases Now in Progress

A study of maternal care among rural relief cases is being conducted in Cayuga, Oneida, and Warren counties by social workers from the Children's Bureau of the United States Department of Labor working in cooperation with the New York State Departments of Health and Social Welfare.

The purpose of this investigation is to determine in selected rural areas of New

York State the number of women receiving prenatal, delivery, and postpartum care (medical and nursing) at public expense as well as the cost and available resources for obtaining such care. The study is being made under the supervision of Beatrice Hall with the assistance of Stella M. Perryman, Edna F. Clark, and Marguerite M. Eisenmann.—*Health News*, August 30, 1937.

UNITED STATES CIVIL SERVICE EXAMINATIONS

The United States Civil Service Commission announces open competitive examinations for the positions of Associate Bacteriologist (\$3,200 per year) and Assistant Bacteriologist (\$2,600 per year). Optional branches are brucellosis, anaerobes, physiology of bacteria, and viruses.

The necessary application forms may be obtained from the Secretary of the Board

of U. S. Civil Service Examiners, at any first-class post office, from the U. S. Civil Service Commission, or from the U. S. Civil Service district office in the Federal Building, Christopher St., New York City. Applications must be on file with the U. S. Civil Service Commission at Washington, D. C. not later than September 20, 1937.

Kings County

DR. THOMAS A. MCGOLDRICK, president of the Kings County Medical Society, has expressed complete accord with Magistrate Charles Solomon's action in suspending the driver's license of a man undergoing insulin treatment for diabetes.

Upholding the jurist's remarks from the bench that autoists suffering from "insulin shock are potential killers," Dr. McGoldrick added the suggestion that the Motor Vehicle Bureau should submit all license applicants to thorough physical examinations instead of mere eyesight tests.

With dozens of his colleagues in Brooklyn who have told the press that the dangers are equally as great from those drivers afflicted with other ailments such as heart disease, paresis, advanced stages of tuberculosis, Dr. McGoldrick said he considered it wise to withhold licenses from all types suffering from ailments marked by sudden collapse, fainting spells and violent attacks.

Magistrate Solomon said he was elated by Dr. McGoldrick's remarks, "especially since his position as Police Department surgeon gives added weight to this physician's statement."

The judge declared he intends to seek a hearing before State Motor Vehicles Commissioner Charles A. Harnett to urge actual changes in the statutes regarding disease-stricken auto license applicants.

Magistrate Solomon said:

"All doctors are required by law to report to the police every case of gunshot wounds. Why shouldn't they be similarly required to file reports with the Motor Vehicle Bureau every case of serious disease or affliction so that the State may compare these with auto license lists. This method would save the bureau of examining thousands of applicants every year and keep its own records up to date."

New York County

DR. SAMUEL H. B. BASCH, ear, nose, and throat specialist and surgeon, died suddenly in his home of a heart attack on Aug. 5. Dr. Basch was chief surgeon at the Fordham Hospital, and chief of staff of the Manhattan Eye, Ear, Nose and Throat Hospital in New York.

DR. JAMES RAMSAY HUNT died on July 22 at his summer home in Katonah, aged sixty-three. He was Professor of Clinical Neurology at the College of Physicians and Surgeons, director of the New York Neurological Institute, consulting neurologist of the Psychiatric Institute, the Babies' Hospital, the New York Eye and Ear and the New York Hospital. He was consulting neuropathologist to the Craig Colony for epileptics and was consulting psychiatrist to the Lying-In Hospital and the Randall's Island Institution.

DR. N. PHILIP NORMAN, who makes a hobby of building miniature replicas of famous ships, won a round trip to France on the *Normandie* by his replica of the showboat *Cotton Palace* used in the filming of Edna Ferber's story, "Showboat" in a contest sponsored by Universal Pictures and the Model Builders Guild of Hempstead.

Ontario County

DR. CHARLES F. NIEDER is the Demo-

cratic candidate in the primaries for the nomination for mayor of Geneva. Local papers say his nomination "is practically a foregone conclusion."

Otsego County

DR. GEORGE H. BRINKMAN, one of the oldest and most prominent physicians and surgeons of Oneonta, died on Aug. 2 after a five weeks' illness. He was seventy-three years old and had been a resident of Oneonta for twenty-seven years. Next March would have marked fifty years of the practice of medicine and surgery for Dr. Brinkman, who had been located in Davenport, Franklin, Sidney and Denver, Colo., before locating in Oneonta.

Suffolk County

A TOTAL OF SEVENTY doctors and wives enjoyed a beef barbecue at Camp Baiting Hollow on July 28 at the dedication of the new Camp Infirmary presented by them to Mr. Harold R. Reeve of Mattituck, who as chairman of the camp committee, received the building in the name of the council.

Speakers at the infirmary dedication included Dr. George J. Fisher, deputy chief scout executive of the Boy Scouts of America, Dr. Stanley Jones of Mattituck and Mrs. Barnhardt.

A HOBBY PROGRAM for the handicapped children of Suffolk County will be the next project of the Women's Auxiliary to the Suffolk County Medical Society. The project just completed by the auxiliary was the furnishing of the new infirmary which was presented to the Boy Scouts' camp at Baiting Hollow by the medical society. The announcement was made by Mrs. William N. Barnhardt, president of the auxiliary, at a meeting held July 28, at the camp with the medical society to dedicate the infirmary building.

The executive board of the auxiliary met on Aug. 10 on board the yacht of Dr. Edward R. Hildreth of Bay Shore, to hear reports of work on the hobby program. Mrs. Hildreth was hostess.

It used to be thought that leprosy never developed in France, but was always contracted elsewhere. Within the past three years, however, it has been discovered that there are ninety-five lepers in Paris, living and moving about freely and without restraint. This has eventuated through a more friendly and considerate treatment,

which has encouraged the lepers to come forward and use hospital facilities provided for them. They are treated with considerable success with a new chaulmoogra oil and cholesterol preparation. Any compulsory measures or "dragooning" are opposed by the medical authorities as likely to send the lepers into hiding again.

Hospital News

Hospital Strike Barred by Injunction

SUPREME COURT JUSTICE ALBERT CONWAY issued a temporary injunction in Brooklyn on Aug 9, restraining members of Local 171, Hospital Employees Union of Greater New York, from calling a strike, picketing or interfering with the patients, the employes or visitors at the Jewish Hospital of Brooklyn. He directed the hospital to post a \$2,500 bond and prepare for an immediate trial after the answer was served.

"The affidavits establish that uninterrupted hospital service for the people of the city is so vital for the preservation of the general health of the community, and especially children, the sick and infirm, that any organized effort to interfere therewith must be regarded as an act of hostility to the common good, and such an unlawful object as to demand the exercise of the equity power of the court to the fullest extent," Justice Conway said.

The operation of a hospital in the community, Justice Conway wrote, affects the public welfare, lives, well-being and health of the people of the State. Moreover, he added, hospitals such as the plaintiff's have patients assigned by or coming through the jurisdiction of the city.

The Justice wrote

It may fairly be said that it is now the policy of the State that the various acts referring to labor disputes shall not apply to those employed by charitable, educational or religious associations or corporations. It is important to note that under the "little Wagner act" the other persons excluded from its application are employees of the State and subdivisions and agencies thereof.

This coupling of persons excluded from the application of the act by the Legislature was not done without reason and intent. The State the subdivisions and agencies thereof may not have their proper functions interfered with by strikes, and neither may charitable educational or religious associations or corporations. Chaos would result, and the public health and welfare would be materially affected.

In his decision Justice Conway incorporated the hospital complaint which recited the disorders that occurred in the hospital on March 15 when members of the union took possession of the kitchen and laundry. The complaint said there were 400 patients then housed in the hospital, forty-six of whom were dangerously ill. There were eighty-seven newly born babies also. Nineteen members of the union were arrested and convicted, but their sentences were suspended.

Social Security for Hospital Employees

THERE CAN BE LITTLE DOUBT that amendments will be made, from time to time, to the Social Security Act, when they seem necessary, and, when that time comes, there is a hospital superintendent out in Ohio who will favor bringing the hospital employees under the protection of its benefits. He is Mr. Harry H. Graef, and he gave his views, without any ifs or buts, at the meeting of the Ohio Hospital Association a few weeks ago. The editor of *The Modern Hospital* remarks that "You may agree or disagree with everything this superintendent says about social security legislation, but you will admire him for the honesty and sincerity of the convictions he expresses."

It is common knowledge, Mr. Graef declares, that hospital employees in general

are paid less for the same kind of work than similar employees in other lines of business or enterprise. Certainly no one would dispute the fact that the average hospital employee could not, on his earnings set aside enough to provide security for old age.

Briefly then, we have a group of employees who admittedly are unable from their own earnings to provide for themselves in old age or to protect themselves from the vicissitudes of employment. We have a federal law, which is to grant and provide for such protection to the employees of the nation. My first reason, then, for disapproving of this exemption is that if there is a need for such protection and we are assuming by virtue of the ex-

istence of the law itself that there is that need, then hospital employees are entitled to its benefits just as much as any other group and have the right to be permitted to participate

My second reason does not deal with the rights or privileges of employees or the fair administration of the Social Security Act, but it is of equal importance. It deals rather with certain basic principles and theories which apparently underlie the administration of many institutions, and which I feel are detrimental to the prestige of hospitals in general and are uneconomic.

It has been my observation that many hospitals for a long time have conducted certain phases of their business on a basis bordering on the practice of the professional mendicant. Whenever it appears there is an opportunity to obtain what looks like "something for nothing" they are the first to appear on the scene and their cries are the loudest for the first and the largest share. However, if there is an obligation to fulfill, and it is their turn to give rather than receive, they always offer a dozen reasons why they should be excused. This seems an unfair and undesirable policy to pursue.

I am completely sold on hospitals and hospital work. I have pride in the position they occupy in the community and the type of service they render. In fact, I am so thoroughly convinced of their worth and the value of their services that I resent seeing them asking concessions on the basis of favor, special privilege or plea of poverty.

They render inestimable service to any community and have the right to expect a fair reimbursement for services on the basis of merit, just as much as any other type of business.

If they expect to be rewarded on the basis of merit, it is illogical to avoid their

just obligations by sentimental pleas based on the character of their activities. If hospitals are justly and properly reimbursed for services, they can and should fulfill their duties.

The hospitals have a two-fold responsibility under our federal Social Security Act, the responsibility of fulfilling a share of our national life and bearing a share of the financial burden. They have the added duty of protecting the welfare of their employees and safeguarding them against unfair discrimination.

The policies and programs of hospitals are chiefly responsibilities of the superintendents. Certain duties and obligations are placed on our shoulders. We should be expected to operate not only an efficient, economic and professionally highgrade hospital, but should also see that our workers are happy and are accorded their rights.

I believe we, as superintendents, have a personal responsibility in this matter and that it is our duty to exert our best efforts that hospital exemption under the Social Security Act be annulled, because our employees have the right to expect benefits of protective legislation, and it is the duty of hospitals to bear their share of this national responsibility.

Let me add that no criticism is intended or implied with respect to the motives or sincerity of hospital representatives who worked to obtain exemption for charitable institutions under the act. My statements represent private opinions only. They are not indicative of the position taken by any organization with which I may be affiliated. I am not aware even if the board of trustees of my own hospital would agree with me. I do feel so strongly in the matter that I present my views to you in the hope that a sufficient number will agree with me making possible official action.

News Notes

PRIVATE AND VOLUNTARY HOSPITALS are not compelled to care for ill and injured patients without pay, even if they are emergency cases, under a ruling of Attorney General John J. Bennett. The opinion was given at the request of Assemblyman William M. Stuart, of Steuben County.

It is not expected that the ruling will have any great effect on New York City hospitals. Members of the United Hospital

Fund, which includes all the larger private institutions, would continue to give emergency service regardless of the ruling, according to David H. McAlpin Pyle, president of the Fund. A similar position is taken by voluntary hospitals in other parts of the State.

Mr. Pyle added:

But this service to auto accident victims is an increasing burden on hospitals and on the

medical profession. The American Hospital Association has just published figures showing that it cost the hospitals of the United States \$17,000,000 last year to care for 265,000 auto crash patients, and the hospitals were able to collect only 51 per cent of the sum. The net loss was \$8,330,000.

AN APPEAL HAS BEEN MADE to the city by the Voluntary Hospital Conference of Queens County for increased allowances for the support of emergency cases admitted to voluntary hospitals, and Dr S. S. Goldwater, Commissioner of Hospitals, has been unofficially informed that similar demands shortly will be made by voluntary hospitals throughout the city.

The city now pays \$3 a day for each medical and surgical patient admitted to a private hospital and approved as a "medical indigent," i. e., one who is unable to pay a hospital bill.

For cancer cases the city rate is likewise \$3 a day, but for the general run of chronics, the per capita *per diem* allowance is only \$1.15. If the current rates were raised only twenty-five per cent, the city's contribution to private hospital support would be increased by \$1,500,000.

NO MORE APPROPRIATE USE could be made of New York State's gasoline tax surplus than to reimburse hospitals for the expense and care of indigent persons injured in motor vehicle accidents. David H. McAlpin Pyle, president of the United Hospital Fund, said in an address over radio station WHN:

"If the state will pay the hospital bills for the poor victims of traffic accidents, the hospitals will be better able to care for the needy ill and injured," Mr. Pyle asserted. "Last year alone the United Hospital Fund's ninety-two member hospitals gave nearly 2,000,000 days of free hospital care. Needless to say, the hospitals could not have made this huge investment in the health of our neighbors and ourselves if they did not receive charitable contributions through the United Hospital Fund."

Mr. Pyle recalled that after the hospitals in Ohio had suffered a \$1,000,000 loss from traffic accident cases from 1931 to 1933, a temporary law was passed to reimburse hospitals from state funds. The law worked so well that it was made permanent, he

said. It would seem, he said, that New York and New Jersey could profit by Ohio's experience.

THERE MUST BE SOMETHING MORE than coincidence in the fact that Independence Hall is situated in Philadelphia, remarks the Rochester *Times Union*, as it notes that the County Medical Society there has sharply attacked the group hospitalization plan now operating in many cities. Even though the Philadelphians' argument seems to belong in the "everyone is out of step but me" category, it is interesting as an example of high-grade hair splitting.

They oppose the plan by which a member of a hospital service corporation secures a stated number of days' treatment by paying a small monthly fee, upon this basis "that it places the participating hospitals in the position of contracting to deliver, for a consideration, the services of certain physicians on the staffs of those hospitals."

In the opinion of the society this "is nothing more nor less than the corporate practice of medicine, illegal in Pennsylvania, where the practice of medicine is limited to duly licensed physicians."

It is too bad, adds the Rochester paper, that the doctors, hospitals and residents of so many cities where this plan is in satisfactory operation, should have been so misguided. What better plan do the Philadelphia physicians offer?

FOUR OUTSTANDING ITALIAN CLINIC PROFESSORS arrived on the Rer on Aug. 5 for a one-month study of leading American hospitals and clinics. They were Giorgio Ferreri, Cesar Frugoni and Guido Egidi, of the University of Rome, and Camillo Arturo Torrigiani, of the University of Florence.

THE ITALIAN HOSPITALIZATION SOCIETY INC., began to maintain free beds for indigent Italian patients in the Parkway Hospital in New York City on September 1 and a staff of Italian physicians will provide medical, surgical and obstetrical services. The members of the Italian staff appointed by the medical board of the Parkway Hospital, will also serve as the medical advisory committee of the society.

Improvements

LUCIUS N LITTAUER, philanthropist and retired glove manufacturer, has given the seven-story building on the southwest corner of Irving Place and Eighteenth Street New York City, to the National Hospital for Speech Disorders, it is announced by Dr James Sonnett Greene, medical director of the hospital

Expanding in its new home and endowed by Mr Littauer, the institution will become known as the Lucius N Littauer Institute for Speech Disorders

The building, formerly occupied by the New York Telephone Co, will be remodeled and equipped by Mr Littauer and will represent a gift estimated at from \$200,000 to \$225,000

The present location of the hospital, 126 East Thirtieth Street, will be used as executive offices for the time being, Dr Greene said, indicating it might be disposed of at some future date The board of directors, he announced, has been re-organized as follows Mr Littauer, president, Dr Bernard Sachs, vice-president, A J, Allis, secretary, Walter Seligman, treasurer, Miss E J Wells, assistant treasurer, Ira Skutch, counsel, and Dr Henry Sage Dunning and A Robert Munro, members

Dr Greene said that Mr Littauer, who is seventy-eight years old, became interested in the hospital through Dr Sachs who was his classmate at Harvard and was formerly president of the New York Academy of Medicine Mr Littauer, who

established the Lucius N Littauer Foundation in 1929, gave Harvard \$2,000,000 in 1935 to establish a graduate school of public administration

A FIVE-STORY HOSPITAL costing \$674,900 is to be constructed by the City of New York at 18-26 East End Avenue and 535-545 East Eightieth Street, northwest corner, from plans by Louis E Jallade, architect The building will have a base 82 9x139 The first floor will be given over to administration and waiting rooms and the upper floors developed for clinics A one-story Department of Sanitation building now stands on the site

A \$9,500 APPROPRIATION for the installation of 202 private cubicles for patients in the treatment room and the third and fourth floor wards of Lincoln Hospital in the Bronx has been approved by the Board of Estimate The expenditure was listed in 1935 when an issuance of \$152,000 in tax notes was authorized for the improvement of the hospital

THE DIRECTORS OF THE Dansville General Hospital have had plans drawn for the contemplated maternity addition and have asked contractors for bids The cost is figured at about \$25,000

At the Helm

FIRST APPOINTMENTS TO THE medical board and staff of Welfare Hospital for the chronic sick, which will be a teaching and research center for Columbia University College of Physicians and Surgeons, Cornell University Medical College and New York University College of Medicine, are announced by Dr S S Goldwater, Commissioner of Hospitals

In affiliation with the Department of Hospitals, the medical staff of the \$7,000,000 hospital under construction on Welfare Island will comprise three divisions of equal rank and each will be under the direction of one of the medical colleges

Dr Goldwater said the physicians nominated by the medical schools to take charge

of the divisions and approved by the department are

For the Columbia division the director of medicine will be Dr Randolph West, and the director of surgery will be Dr William Barclay Parsons

For the Cornell division the director of medicine will be Dr Irving Sherwood Wright, and the director of surgery will be Dr Ralph Firestone Bowers

For the New York University division the director of medicine will be Dr Norman Jolliffe, and the director of surgery will be Dr William Howard Barber Dr Wright is to be president of the medical board, with Dr West as vice president, and Dr Jolliffe as secretary

Medicolegal

LORENZ J. BROSVAN, ESQ

Counsel Medical Society of the State of New York

Claim of Foreign Body in Throat

A doctor specializing in ear, nose, and throat work was served with a summons and complaint in a malpractice action in which the charge in the complaint was that the defendant had treated a certain infection in the neck of the plaintiff negligently, in that he had inserted a rubber drain in the neck of the plaintiff and had failed to remove the same so that it lodged therein for many months, causing her great damages. The defendant, upon receipt of the said papers, had no recollection of ever having treated the plaintiff named in the summons and complaint at any time. Before the case came on for trial it was ascertained that the plaintiff's name, as specified in the legal papers, was a different name from the one she had been known by at the time she claimed to have been treated by the defendant. The defendant, upon checking over his records, ascertained that a girl about sixteen years of age, who apparently was the plaintiff under her earlier name, had, on one occasion five years before, come to him complaining of a large swelling on the left side of her neck, which had been previously opened and drained by another doctor. The defendant found that he had diagnosed the condition as cervical adenitis, and had dressed the wound and told her to return in a few days. The doctor was unable to ascertain from his records whether she did return to him at any time for any further treatment and he was unable to recall such facts, although he was certain that he did not operate upon her in any way.

A bill of particulars was obtained from the plaintiff for the purpose of ascertaining the number of times it was claimed that the defendant treated her and, according to the bill of particulars, the plaintiff was treated over a period of four months. She specifically claimed that the defendant had treated her about forty times in all and that he had on various occasions lanced pus pockets in her throat and had inserted various rubber drains in the incised regions. The claim specifically stated that on one occasion the defendant neglected the drain inserted by him on a previous occasion and that instead he inserted a second drain over the old drain and that the old drain was

permitted to remain in the neck for a long period of time until removed by another physician.

Investigation of the situation revealed that at a date after the last time it was claimed she was treated by the defendant, the plaintiff went to the clinic of a large hospital where she received treatment for a condition involving the glands of her throat. The records of that institution having been made some years before were difficult of interpretation. An entry appeared on one day stating that a rubber drain was removed, although no entry on a previous day showed that one had been inserted. The physicians who treated her at the clinic were unable to recall the matter at all.

When the case came up for trial without a jury the plaintiff undertook to build a case around the said entry in the clinic records and to claim that said entry indicated conclusively that the defendant had in fact permitted a rubber drain to remain in the throat for some months, causing her various injuries, which she undertook to describe. She testified that she had been cared for at the defendant's office on at least forty occasions, and was corroborated in such testimony by members of her family and by a taxi driver, who testified that he remembered the matter very well, since on each of the said forty occasions he had taken her and a member of her family to the defendant's office at a flat rate.

The turning point in the case, however, was when on cross-examination the plaintiff was asked if she was able to point out the defendant in the court-room. Although she was given ample time to pick out the defendant, and although he was sitting at the counsel table in full view she was unable to identify him. The defendant, of course, testified to treatment as outlined above.

At the conclusion of all the testimony the court directed a verdict in favor of the defendant and commented in so ruling upon the significance of the fact that the action was delayed for over five years, and upon the plaintiff's failure to identify the defendant.

Across the Desk

The Heart Disease Racket

THIS CONTINUOUS VAUDEVILLE, three-ring circus, or high jinks that we humorously call civilization is always putting on some new act to pop the eyes of the on-lookers. The latest amazing performance is what is known as "the heart-disease racket" in New York City. In this "racket," or scheme, dishonest lawyers, doctors, insurance agents, and policyholders conspire together to defraud the insurance companies by cooking up bogus cases of heart-ailments and collecting disability payments, which were divided up among the racketeers, probably much in the same way as the crews of Captain Kidd and Blackbeard shared the proceeds of their piracy.

Thirty-nine persons have been indicted for these frauds, including ten physicians, seven lawyers, two insurance agents, and twenty policy holders. More indictments are in prospect. Eight large insurance companies were the victims, and the swag is said in some cases to have run as high as \$12,000 a year, paid for illnesses that never existed.

Secret of What Won the War

This is exactly the sort of news that is cabled to Europe and appears in the papers over there to picture to Europeans the sort of country we have here. The "American news" in the transatlantic sheets is news of murders, robberies, kidnappings, racketeering, and every kind of crime in the calendar. Many European folks imagine that our population is made up largely of gangsters, gunmen, and sharpers. The movies displayed over there add wild western cowboys and handsome heroes who grab villains by the neck or feet and toss them lightly out the window or over the cliffs.

That is said to be the reason why the proud German army, hitherto unconquered, turned and put for home and fatherland when the American doughboys appeared on the battlefield. The German soldiers had all seen what American men could do in a fight in the movies, and they well knew in their own souls that they were not made of any such stuff. Wellington said that

Waterloo was won on the playing fields of Eton—perhaps the Great War was won on the movie lots of Hollywood.

Doctors in Topsy-Turvy Land

Well, now the American doctor is added to the "American news" in the papers of Great Britain, France, Germany, Italy, and other lands. A doctor is supposed to be somebody who makes sick people well, but here we have a group of physicians who made well people sick, or sick enough, anyway, to collect disability payments. That is what makes this racket a vaudeville or circus act, it is something contrary to nature, like the bearded lady or the two-headed calf. Imagine a doctor saying to a patient, "How would you like to have angina and a check for \$1,000?" It is a scene that belongs in Coney Island's house upside-down.

It must be confessed, however, that the medical men were not the "big shots" in this racket. It was run, it seems, by a number of gentlemen of the legal profession, whose "runners" or agents approached insurance policy holders and persuaded them to take advantage of the disability clauses in their insurance policies. The legal luminaries found struggling physicians who were having a tough job to keep their heads above water in the hard times, and tempted them into the scheme with promises of glittering rewards. One reward they overlooked was to have their names blazoned across the front pages of the newspapers as partners in a racket with an unsavory crew of scalawags. Worst of all, perfectly reputable and high-minded physicians, too, were victimized without knowing anything about it. Policy holders in the racket were sent to visit these doctors, coached to describe symptoms that would be jotted down on the doctors' records to indicate heart disorders. Sometimes drugs would be given before the visit to produce confirmatory symptoms. All this "built up" the evidence, so that if the insurance company refused payment, as often happened, a jury would enforce the claim.

The Moral of the Tale

After all, but ten physicians out of the many thousands in New York City and State are involved in this racket, and so far they have been only indicted, not proven guilty, or brought to trial. Under the law, they are presumed to be innocent until guilt is proven. No possible stigma attached to the medical profession. But, at the same time, this unfortunate affair carries a serious warning that the entire profession should heed. If the game worked so well for a time in New York City, is it unlikely that crooks, high and low, will try it out elsewhere? Insurance companies are perpetual targets of swindlers, and it would be strange indeed if this new device were overlooked. A few years ago a fat volume was published, called "Crimes of Insurance," and hundreds of pages were devoted to the fires, murders, and other kinds of mischief perpetrated by rascals trying to extract money from companies formed to aid widows, orphans and other victims of ill-fortune. It is an industry that never ends, and takes no holiday, except behind prison bars.

Physicians, then, should be on their guard. Dr O F Hedley, who served as medical adviser to the office of the United States attorney investigating this racket, wrote an article about it that came out in the *Journal* of the AMA a few weeks ago. He advises doctors to exercise the greatest caution if unknown patients are referred to them with "complaint of angina pectoris and no very sound objective evidence on which to base a diagnosis of cardiovascular disease." If the doctor innocently accepts the new patient's description of his symptoms, and writes them down in his case records, he may later be amazed to find himself called as a witness and used as a tool in some case that reeks of fraud.

A plan recommended by Dr Hedley is "the practice employed by some consultants of limiting prognoses in ambulatory patients to the relatively near future." This, he points out, makes it much more difficult to use the report subsequently as a basis for a claim of total and permanent disability. Furthermore, he advises that the consultant, if in any doubt, should obtain a written statement from the referring physician and patient concerning their intention of using the report for litigation or for insurance claims. No racketeers would be very likely to call a consultant into court if he could bring with him this evidence of their bad faith. Also, in examining a patient, remarks Dr Hedley, "the possibility of surreptitious digitalization should be borne in mind, especially in interpreting electrocardiograms showing tracings compatible with digitalis effects."

Turning to the less innocent doctors who figure in this shady business, it is undoubtedly true that every city has its physicians who have been hard hit by the depression, who have families to feed and shelter, and who do not know where to look for a way out of their desperate difficulties. It is to such men that the racketeers come, promising lucrative rewards for "a bit of deception that harms nobody except a big rich insurance company." It sounds like picking up money in the street. Before long, however, the doctor finds himself involved in a criminal conspiracy that makes him liable to a term in prison, if discovered, he finds that his part of the swag is very small indeed, and, when the district attorney is done, he finds his name blackened forever and his medical career finished. Taking it strictly on a dollars and cents basis, with all moral considerations left out, it is, as the saying goes, "a mug's game," and it is a thousand times better to realize it before than too late.

Why Editors Go Mad

A LAUGHABLE TYPOGRAPHICAL SLIP occurred in these pages on August 15, laughable because it was so evident that no one could possibly be deceived by it. An error in a scientific article might conceivably confuse somebody and do harm, though not so badly as in the old story of the man who treated his own ills with a "doctor book," and died of a typographical error.

In this case two passages on pages 1476 and 1477 were transposed, so that on one the reader was solemnly informed that the Delaware legislature had enacted a law providing

"That the Medical Association of Georgia establish at the office of the Association in Atlanta a Public Relations Bureau similar to that now operated by

the Medical Society of the State of New York."

And on the other was the amazing news that the Medical Association of Georgia was licensing chiropractors! Exchange the types, and you find Delaware licensing chiropractors and Georgia setting up a Medical Public Relations Bureau

The next paragraph began

Nor is that all," and went on to recommend sponsoring a doctor "for a legislative post," instead of "a legislative post," as written

All of which explains why editors are so rapidly filling the nation's best insane asylums

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

The Thyroid and Its Diseases By J. H. Means, M.D. Being an account based in large measure on the experience gained in the Thyroid Clinic of the Massachusetts General Hospital. Octavo of 602 pages, illustrated. Philadelphia, J. B. Lippincott Company, 1937. Cloth, \$6.00.

This book may be highly recommended to the specialist and general practitioner. While disclaiming to be encyclopedic in its scope, it comes very close to being such. The thyroid gland, its hormones, the relation of the thyroid to other endocrine glands, the pathology, symptomatology, ex-

aminations, medical and surgical treatment of simple goiter, myxedema, cretinism, toxic goiter, nodular goiter, malignancy, inflammation, and anomalies are splendidly discussed.

The author takes up the use of thyroid medication in other diseases than those of thyroid origin, such as obesity, hypometabolism, sterility, habitual abortion, skin diseases, heart block, deafness, vertigo, and diseases of the eye. Total thyroidectomy in diseases not of thyroid origin, such as congestive heart failure, angina pectoris, diabetes, and leukemia, receives proper atten-

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

tion Equally important is a fourteen page discussion of "fact and fancy in matters thyroid."

The book makes easy reading is practical, and on all controversial points gives the authors' conclusions and their reasons therefor. The printing is excellent, the charts are sufficient and very illustrative, the index good, and the bibliography provocative and happily not over exhaustive. Dr Means and the publishers are to be complimented on this splendid work.

MEYER A. RABINOWITZ

Light Therapy By Frank Hammond Krusen, M.D. Second edition, revised and enlarged. Octavo of 238 pages, illustrated. New York, Paul B. Hoeber, Inc., 1937. Cloth, \$3.50.

In this second edition of his book the author has gathered a valuable fund of information on light therapy. Because of excellent grouping and tabulation, the value of the work is even further enhanced. The review of mechanical equipment available is inclusive and thorough, with a totally unbiased description of the characteristics of each item. Convincing case reports and precise detail of technique add to the value of the work. Of particular interest are the notes on the treatment of erysipelas and the changing opinion of the value of actinotherapy in pulmonary tuberculosis. A most interesting historical sketch introduces the text which then continues to completely cover its subject in a truly fascinating manner. Adequately illustrated, clearly printed and well bound, the book may be highly recommended both to the student and the practitioner of light therapy.

JEROME WEISS

Endocrinology Clinical Application and Treatment. By August A. Werner, M.D. Octavo of 672 pages, illustrated. Philadelphia, Lea & Febiger, 1937. Cloth, \$8.50.

The stupendous progress made by endocrine research in recent years has aroused the interest even of the more skeptical members of the medical profession. This interest is documented by the publication of several books dealing with the clinical application of endocrinology. Dr. Werner's treatise is among the more useful of this group. His approach shows the result of inspiration received from the late Dr. Engelbach whose clinically important subdivision of endocrinopathies according to age groups he has followed conscientiously. In favorable contrast to some other recent publications on the subject, the author shows familiarity with both the clinical aspects of endocrine disorders and the

physiology of the endocrine glands. His book is well illustrated and documented with a large number of interesting case histories. It is a valuable guide for the practitioner and also contains interesting information for the student of endocrine problems.

MAX A. GOIDZIEHER

Safe Childbirth The Three Essentials Round Brim, Flexible Joints, Natural Posture. By Kathleen O. Vaughan, M.B. Octavo of 154 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$3.00.

Another book by an author whose wealth of experience in India, Kashmir and Egypt has provided her with the interesting material which has been so clearly presented. An answer can be found here to that question so frequently asked: "Why is childbirth in the native woman so much easier than in her civilized sister?" One cannot help but be impressed if not entirely convinced by the author's logically presented data favoring round brim, flexible joints and normal posture as a means to safe childbirth.

There is contained in this brief volume much for deep consideration by anyone whose interests are directed towards obstetrics.

JAMES L. O'LEARY

Materia Medica, Toxicology and Pharmacognosy. By William Mansfield, A.M. Octavo of 707 pages, illustrated. St. Louis, The C. V. Mosby Company, 1937. Cloth, \$6.75.

Pharmacognosy means the science of drugs in all their relations: sources, description, preparation, action, dosage, etc." This study in recent years has been considerably neglected, largely because some other fields seem of more burning interest and of more importance in these days of simplification of drug administration and ready made combinations of drugs. It does seem though, that one should know the appearance of such drugs as the fog-glove about which we talk so much and do not even know it when we see it growing in the fields. The description of drugs from plants, barks, leaves, seeds, etc. makes one realize that he has forgotten most of what he knew about such things.

There is a very good section on poisons which is quite full and glossaries of therapeutic and botanical terms. Most physicians will find that this book covers some things out of the usual line of thought and very useful for reference.

WILLIAM E. MCCORMICK

Home Care of the Mental Patient By Arrie Querido 16mo of 93 pages New York, Oxford University Press, 1936 Cloth, \$1 00

The aim of this book is to convey in simple language the basis of the behavior of those who are mentally sick. In the Netherlands, mentally sick people are apt to be treated more in their homes than to be committed to mental hospitals. The effort is directed to educating the community to looking after the mentally sick in its own midst.

There are many valuable points mentioned in the book that will be a help not only in managing mentally sick people, but also in the detection of the early manifestations of mental disorder.

It is a practical and valuable little book.

IRVING J SANDS

International Clinics A quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, Neurology, etc. Edited by Louis Hamman, M.D. Volume 4, 46th Series, 1936 Octavo of 352 pages, illustrated Philadelphia, J. B. Lippincott Company, 1936 Cloth \$3 00

This issue contains articles by many well known writers on medical topics, and covers a wide field. Phases of pulmonary tuberculosis, lung abscess, and emphysema are among the lung conditions presented. Gastroscopy, gall bladder disease, nutritional edema, hypertension, essential thrombocytopenic purpura, bedside recognition and treatment of cardiac irregularities, and a clinic on cardiovascular diseases are other subjects treated in this volume. It contains also papers on acne and scabies. This issue of this quarterly is deserving of careful study, as much can be learned from its use.

HENRY M MOSES

Preoperative and Postoperative Treatment. By Robert L. Mason, M.D. Octavo of 495 pages, illustrated. Philadelphia, W. B. Saunders Company, 1937 Cloth, \$6 00

This volume brings up to date the recognized preoperative and postoperative treatment in 467 pages of text and 123 photographs and black and white illustrations. It also contains contributions from twelve different Boston physicians and surgeons. The book itself is divided into two parts: the first containing chapters on general topics, such as, anesthesia, shock, acidosis, alkalosis, etc. The second part contains chapters on regional topics, such as care of the ears, nose, throat, diseases of the gall bladder, diseases of the stomach and duodenum, hernia and traumatic injuries. Throughout the entire work, the author

and his contributors have succeeded exceptionally well in including in their description the various methods of treatment which are definitely recognized, a fact that makes the volume exceptionally valuable as a desk reference book to the busy practitioner of surgery.

Some of the chapters in the book, however, could contain a little more detail in regard to the treatment of important conditions, such as shock. In general this work has treated the various topics in a very excellent manner, but it will not take long (as the past has proven) for many of the suggested forms of treatment to become obsolete, when that time arrives, let us hope that Dr. Mason can give us another edition.

HERBERT T WIKLE

Amino Acid and Ammonia Metabolism in Liver Diseases. By Esben Kirk. Octavo of 147 pages. Copenhagen, Levin & Munksgaard, Publishers 1936 Paper, Danish Kroner 10

This monograph is a compilation of the investigations which Dr. Kirk performed while resident physician in the Bispebjerg Hospital, Copenhagen. It includes studies both in dogs and human beings and is a very comprehensive summary of the role of the liver in protein metabolism. It takes up in great detail the physiology of deamination of the amino acids, the formation of urea in the liver and ammonia urea partition. There are many tables and charts showing the result of his work in the normal and a comparison of these findings with those occurring in various diseases of the liver. He places great stress on the blood ammonia concentration and has analyzed them, both in systemic venous blood and portal blood, showing especially, that in cirrhosis of the liver there are sufficient functional derangements to result in an increase in blood ammonia concentration. He finally describes an ammonia tolerance test for the diagnosis of liver cirrhosis. The author maintains however, that this test does not represent a functional test of liver tissue, but is a procedure for the detection of anatomical abnormality, represented by abnormally developed anastomoses between portal vein and vena cava. These increased ammonia values then are expected to be found in all cases of partial obstruction, besides those of liver cirrhosis. The ammonia tolerance test encompasses a difficult analytical technique and would hardly be suitable for routine use in hospital practice. The monograph closes with a summary of 57 cases.

HISTOGENESIS OF LAENNEC'S CIRRHOSIS

JAMES FINLAY HART, M D and JAMES R LISA, M D, *New York City*

This is a report of a study of thirty-six cases showing liver pathology that came to autopsy at the City and Midtown Hospitals in New York City from 1926 to 1937. The main object of this investigation was to determine, if possible, the histogenesis of Laennec's cirrhosis. We will give a brief review of the pertinent literature, report our findings, and then our conclusions. We will use the term Laennec's cirrhosis in preference to any of the other synonyms commonly employed for this condition because we think that Laennec's classical description completely covers this form of cirrhosis whereas other terms such as portal alcoholic, atrophic, etc., are incomplete and misleading.

Diagnostic Criteria

We realized at the start that some diagnostic criteria for Laennec's cirrhosis had to be established as there were variations due to degree and duration of involvement with many borderline and mixed types. The consensus of opinion, as shown by Moon,¹ seems to be that this form of cirrhosis is characterized by a change in the liver architecture. The normal lobules consisting of cords of cells, radiating spoke-like from the central vein to the periphery, have been supplanted, more or less, by adenomatous-like masses of hepatic cells that have lost their radiating arrangement and have been separated from their central veins.

These new formations, called nodules, may partially or completely fill the liver and there may usually be found, at the periphery, a parenchymal cell degeneration with a neighborhood leukocytic infiltration and a fibrous tissue proliferation.

It was further apparent that owing to the great amount of confusion regarding the pathologic processes involved under this term, it would be advisable to keep certain questions in mind during the study. The following queries were formulated for this purpose:

- 1 Is Laennec's cirrhosis a specific disease entity?
- 2 Is it the result of any one or any combination of lesions?
- 3 Is it the result of a new set of factors becoming active after liver damage?

A Specific Disease Entity?

The most commonly held belief is that Laennec's cirrhosis is a specific disease entity. This has been the general feeling for many years with the admission however, that it could not be proved. Because certain histologic changes closely associated with infection are present in the great majority of cases it is commonly held that some unrecognized low grade infection is the producing agent and because it usually progresses to a fatal stage it is thought that the infection is continuous.

Although we can distinguish the intermediate and late stages of this condition we are unable to recognize any characteristic early change. We find, after a perusal

Read at the Midtown Hospital Clinical Conference, January 18, 1937, St Elizabeth's Hospital Staff Meeting, March 2, 1937.

of the available literature, very little said about the early stage, only one investigator, Mallory² making any mention of it. He states that a fine-to-coarse acidophilic reticulum in the cytoplasm of the parenchymal cells is characteristic and diagnostic, that it may be found before evidence of cirrhosis is present, and that the degenerative changes occur throughout the lobule but are usually most marked, at least in the early stages, around the central vein. This acidophilic reticulum is found as well in the periphery of the nodules. This idea of its importance is shared by very few investigators, Moon believing that it simply represents activity of the process rather than a diagnostic feature.

All other references state or infer that the diagnosis is not made until the nodules of regeneration have formed and that the activity of the disease is determined by the condition of the cells in the periphery of the nodules. Therefore, because of the paucity of data relating to the incipient or prenodular stage and because of the abundance of references to the later or nodular form, we are suspicious that there is no specific early stage and that the condition is not recognizable until the liver is damaged enough to be nodular.

Hence without a recognizable early stage one hesitates to believe that Laennec's cirrhosis is a specific disease entity.

Result of Any One or Any Combination of Lesions?

A certain number of writers today believe that Laennec's disease may follow any one or any combination of lesions. Mallory² states that pigment and healed yellow atrophy (central necrosis) very frequently are indistinguishable from "alcoholic" cirrhosis. These types then are potential cases of Laennec's disease. Observing his table (see accompanying Table I) we note these classes stand second and third in order of frequency, and added to the frank "alcoholic" represent a total of 365 out of the 550 cases of cirrhosis. Making a further correction by dropping the 104 not classified cases we have 365 out of a possible 446 (82%) either definitely or potentially of the Laennec type. Again disregarding the 270 that are positive Laennec's and the 104 that cannot be classified, we find that the pigment and healed yellow atrophy varieties constitute fifty-four per cent of the remainder. According to Mallory then, "alcoholic" cirrhosis may follow two different forms of cirrhosis and these two forms constitute

over fifty per cent of the primary cirrhotic states as tabulated.

Chapman³ says that atrophic cirrhosis with ascites represents a common end stage of any type of diffuse chronic degenerative or inflammatory lesions of the liver in which its structure is greatly injured or disorganized. He does not believe that it is necessarily a specific disease entity and says that it is well-established that diffuse hepatitis of almost any type may progress to cause portal obstruction and ascites.

Moon¹ in an exhaustive review of experimental cirrhosis in relation to human cirrhosis, showed that a condition in animals, similar to Laennec's in man, could be produced by a number of inorganic chemicals, organic substances, serologic agents, and infections. Furthermore, in many instances combinations of agents were found more efficacious than either agent alone. He states it is admitted that congenital luetic cirrhosis may result in a form of cirrhosis resembling Laennec's.

Hence, from the opinion of several serious workers in this field, together with the evidence of experimental studies made on animals, we are led to believe that Laennec's cirrhosis can follow any liver lesion or any combination of liver lesions.

This was the belief of McCabe and Hart⁴ and our findings in the thirty-six cases here reported lead us to the same conclusions.

In Table II we have listed the cases as they were registered in the autopsy records. A perusal of this table brings out clearly the difficulties encountered in classifying any group of cirrhotic livers. As we have previously stated great confusion exists because of the degree and duration of the involvement and because of the large number of borderline and mixed types. It will also be noted that distinctions were not made on pathology alone, the clinical history assisting in many cases. This fact thereby favoring the multiple etiology of cirrhosis. It has been customary in our hospitals to use an arbitrary standard in registering Laennec's cirrhosis. Those livers that weigh over 1200 grams are called chronic hepatitis while those that fall below that figure are termed Laennec's disease.

Result of a New Set of Factors Becoming Active After Liver Damage?

The third consideration in our study involves the possibility that Laennec's disease is the result of new factors, primarily non-pathogenic, that have become perverted as the result of damage to the liver. If we

review the accepted diagnostic criteria for this form of cirrhosis we find a damaged liver is a necessary preliminary. This damage, however, must be of a certain type. It must be such to cause a change in the architecture of the lobule.

TABLE I—CASES OF CIRRHOSIS AT THE BOSTON CITY HOSPITAL

Total number of autopsies during the past 35 years	9346
Total number of cases of well marked cirrhosis of the liver	550 5 88%
They are classified as follows	No %
1 Alcoholic cirrhosis	270 48.90
2 Pigment cirrhosis	49 8.90
3 Healed acute yellow atrophy	46 8.36
4 Syphilitic cirrhosis	28 5.09
5 Colon bacillus cirrhosis	25 4.54
6 Obstructive cirrhosis	24 4.36
7 Obstructive and colon bacillus cirrhosis	3 0.54
8 Cancer cirrhosis	1 0.18
9 Not classified	104 18.90

The Required Preliminary Liver Damage

We decided from our studies that central necrosis was the required preliminary liver damage. This necrosis would have to be severe enough, however, to embrace a sufficient number of cells about the central vein so that a collapse of the lobule occurred. There would then follow a permanent change in the architecture of the lobule which would correspond to the diagnostic criteria for Laennec's cirrhosis as previously stated.

Histologic Changes in Central Necrosis

It would be of interest at this time to trace the changes in the liver which are brought about by central necrosis. We note that damage to the liver is very largely a parenchymal cell injury. This cell, by far the most vulnerable structure in this organ, is especially susceptible to necrosis. Two forms of injury—pressure and toxins—are commonly followed by death of the cells. Pressure necrosis is found in cardiac decompensation, biliary obstruction, and infectious biliary hepatitis. The cardiac type is wholly central while the others are peripheral. The sum total of the three, however, is negligible when compared with the toxic group.

Toxic cirrhosis, on the other hand, is very commonly found. It constitutes all but a fraction of hepatic injuries and even then may be a complication of the remainder. It is almost exclusively a central necrosis. While the process may extend to include the midzone and the periphery, for all practical purposes it might be considered primarily central. Toxic necrosis, then, appears to be the main form of liver response to injury, and, being central, makes necrosis of the center of the lobule the commonest form of pathologic change in the liver.

We note that this form of necrosis varies with the strength of the toxins and with the duration of their influence. Mild doses may kill only one or two cells at a time while more severe ones may cause necrosis of the central area or even of the central and midzonal. Very large doses can be seen at times to poison every cell in the lobule. The duration of the toxic action varies considerably. We see many cases that are acute, for example, acute yellow atrophy with a sudden onset and a rapid course. Again we have what we feel is a longer action of the poison in the subacute variety of yellow atrophy. How long this necrotizing dose of toxin might continue to act is hard to say. Some infections

of the available literature, very little said about the early stage, only one investigator, Mallory² making any mention of it. He states that a fine-to-coarse acidophilic reticulum in the cytoplasm of the parenchymal cells is characteristic and diagnostic, that it may be found before evidence of cirrhosis is present, and that the degenerative changes occur throughout the lobule but are usually most marked, at least in the early stages, around the central vein. This acidophilic reticulum is found as well in the periphery of the nodules. This idea of its importance is shared by very few investigators, Moon believing that it simply represents activity of the process rather than a diagnostic feature.

All other references state or infer that the diagnosis is not made until the nodules of regeneration have formed and that the activity of the disease is determined by the condition of the cells in the periphery of the nodules. Therefore, because of the paucity of data relating to the incipient or prenodular stage and because of the abundance of references to the later or nodular form, we are suspicious that there is no specific early stage and that the condition is not recognizable until the liver is damaged enough to be nodular.

Hence without a recognizable early stage one hesitates to believe that Laennec's cirrhosis is a specific disease entity.

Result of Any One or Any Combination of Lesions?

A certain number of writers today believe that Laennec's disease may follow any one or any combination of lesions. Mallory² states that pigment and healed yellow atrophy (central necrosis) very frequently are indistinguishable from "alcoholic" cirrhosis. These types then are potential cases of Laennec's disease. Observing his table (see accompanying Table I) we note these classes stand second and third in order of frequency, and added to the frank "alcoholic" represent a total of 365 out of the 550 cases of cirrhosis. Making a further correction by dropping the 104 not classified cases we have 365 out of a possible 446 (82%) either definitely or potentially of the Laennec type. Again disregarding the 270 that are positive Laennec's and the 104 that cannot be classified, we find that the pigment and healed yellow atrophy varieties constitute fifty-four per cent of the remainder. According to Mallory then, "alcoholic" cirrhosis may follow two different forms of cirrhosis and these two forms constitute

over fifty per cent of the primary cirrhotic states as tabulated.

Chapman³ says that atrophic cirrhosis with ascites represents a common end stage of any type of diffuse chronic degenerative or inflammatory lesions of the liver in which its structure is greatly injured or disorganized. He does not believe that it is necessarily a specific disease entity and says that it is well-established that diffuse hepatitis of almost any type may progress to cause portal obstruction and ascites.

Moon⁴ in an exhaustive review of experimental cirrhosis in relation to human cirrhosis, showed that a condition in animals, similar to Laennec's in man, could be produced by a number of inorganic chemicals, organic substances, serologic agents, and infections. Furthermore, in many instances combinations of agents were found more efficacious than either agent alone. He states it is admitted that congenital luetic cirrhosis may result in a form of cirrhosis resembling Laennec's.

Hence, from the opinion of several serious workers in this field, together with the evidence of experimental studies made on animals, we are led to believe that Laennec's cirrhosis can follow any liver lesion or any combination of liver lesions.

This was the belief of McCabe and Hart⁵ and our findings in the thirty-six cases here reported lead us to the same conclusions.

In Table II we have listed the cases as they were registered in the autopsy records. A perusal of this table brings out clearly the difficulties encountered in classifying any group of cirrhotic livers. As we have previously stated great confusion exists because of the degree and duration of the involvement and because of the large number of borderline and mixed types. It will also be noted that distinctions were not made on pathology alone, the clinical history assisting in many cases. This fact thereby favoring the multiple etiology of cirrhosis. It has been customary in our hospitals to use an arbitrary standard in registering Laennec's cirrhosis. Those livers that weigh over 1200 grams are called chronic hepatitis while those that fall below that figure are termed Laennec's disease.

Result of a New Set of Factors Becoming Active After Liver Damage?

The third consideration in our study involves the possibility that Laennec's disease is the result of new factors, primarily non-pathogenic, that have become perverted as the result of damage to the liver. If we

the surviving cells press against the folded and matted stroma of the collapsed sinusoids and have so adjusted themselves that groups of them are parallel to each other rather than in the normal radial arrangement.

Liver cell regeneration Corresponding with the removal of the necrotic cells, liver cell regeneration begins. This regeneration occurs exclusively at the periphery of the cords, proceeds rapidly, and grows toward the center of the lobule, pressing the uninjured cells of the cord down the trabeculae. There is an urge on the part of the liver to replace the cells that are lost and it is this urge misdirected by the abnormal position of the cords and stroma that produces the bizarre grouping of cells called nodules.

Circulatory changes The circulation of the lobule has taken on marked changes. Due to the collapse of many sinusoids the portal blood supply is lowered. A compensatory increase in the hepatic blood flow occurs and we find the hepatic artery radicles becoming the main blood supply to the newly formed nodules.

Connective tissue growth There is a negligible amount of new connective tissue found in central necrosis even after the nodules are well-established. Studies by MacCallum⁶ and Beaver and Robertson⁶ showed that this existing tissue was with little exception the original stroma.

Healed Stage

We now have a damaged liver with formation of nodules and a consequent change in the circulation. This stage is usually classified as healed toxic cirrhosis or healed yellow atrophy. Mallory considered this an end process and felt that it differed from progressive "alcoholic" cirrhosis. According to our accepted diagnostic criteria, however, healed toxic cirrhosis is indistinguishable from Laennec's cirrhosis. Toxic cirrhosis produces nodules and a change of architecture while Laennec's disease depends for its diagnosis on the same structural changes. Our studies lead us to believe that healed central necrosis, sometimes designated healed toxic cirrhosis, is the required preliminary damage to the liver in Laennec's cirrhosis.

Chronic Progressive Stage

Nevertheless, even if we accept toxic cirrhosis as the required preliminary damage to the liver, we must offer some explanation for its metamorphosis into chronic progressive cirrhosis. We must show some factor or factors that become active after

the original toxin has disappeared. Accordingly we note that either one or two factors may now add further injury to the damaged liver. An additional insult such as a return of the original toxin or the appearance of a new toxin, may occur, or, if no further scarring from toxins ensues, the time factor can come into play.

Precipitating factors Let us first consider the possibility of *additional insults*. Continued use of arsenic or cinchophen after clinical signs of liver damage is evident

Fig 3 Early central degeneration of the lobule in a case of biliary cirrhosis. This shows the possibility of central necrosis occurring in cases of biliary cirrhosis.

Fig 4 Early peripheral degeneration of a nodule, showing parenchymatous degeneration of the hepatic cells with infiltration by polymuclear cells and fibroblasts.

Fig 1 Biliary cirrhosis

Fig 2. Early distortion of the architectural pattern of the lobule illustrating the transition of the lobule to nodule. The central vein is displaced towards the periphery and the radial arrangement of the cords is fairly well preserved. In the circle are two areas of the periphery showing a tendency to nodule formation in contrast to the radial arrangement seen in the remainder of the lobule

which at times are known to produce hepatic necrosis, such as scarlet fever, run three to four weeks of active infection. Arsenic and cinchophen at times may produce acute yellow atrophy and at others the subacute form with apparently the same dose. Even though these drugs may be given over a long period, there is great uncertainty when they will act on the liver, for they will cause the acute form as quickly as the subacute after long continued administra-

tion. Most hepatotoxic substances act with the same questionable outcome. Experimental work on rabbits however, shows a definite relationship between the size of the dose and the length of time it is given. It has been confirmed many times that sublethal doses of hepatotoxic substances, if repeated in rabbits, lead to subacute toxic hepatitis and then to full-blown cases of cirrhosis.

We further noted that the combination of two or more mild toxins acting in unison on the liver often produced hepatic necrosis. Likewise the combination of mild pressure and mild toxins as well as the superimposing of either mild pressure or a mild toxin on a previously damaged liver brought about central necrosis. Such combinations are well-known in experimental hepatitis and are frequently quoted in clinical literature, but it would seem that insufficient emphasis is given to them for the part they play in producing parenchymal cell death.

Repair Following Central Necrosis

Removal of dead cells About seven to ten days after the injury the dead cells are removed. The polymorphous and endothelial leukocytes acting as phagocytes clean up the debris. As the liver has peculiar healing methods, no new cells are found at the place of necrosis to replace the ones lost. Likewise a negligible amount of connective tissue is thrown out at this place to form scar tissue. Hence the space left by the removal of the necrosed cells makes little or no effort to fill up.

Collapse of the lobule After the debris is cleared away, especially where a group of cells is affected, the delicately supported lobule, unable to withstand the surrounding pressure, collapses. As toxic necrosis is primarily central, this collapse invariably occurs at the central vein. In the more severe cases, most of the lobule may be involved and even the whole structure may be disorganized. This collapse of the lobule marks an important step in the histogenesis of Laennec's cirrhosis. Such a collapsed lobule probably never straightens itself out. Instead it thereby initiates the change in architecture that is so essential to the diagnosis.

Let us briefly describe the appearance of the lobule after the collapse has occurred. It has become smaller than normal. The central vein is usually pushed to one side, the distance being greatest in the severe cases. All but a few sinusoids have collapsed, and these are quite engorged with blood. The remaining portions of the hepatic cords have moved centrally so that

the surviving cells press against the folded and matted stroma of the collapsed sinusoids and have so adjusted themselves that groups of them are parallel to each other rather than in the normal radial arrangement

Liver cell regeneration Corresponding with the removal of the necrotic cells, liver cell regeneration begins. This regeneration occurs exclusively at the periphery of the cords, proceeds rapidly, and grows toward the center of the lobule pressing the uninjured cells of the cord down the trabeculae. There is an urge on the part of the liver to replace the cells that are lost and it is this urge misdirected by the abnormal position of the cords and stroma that produces the bizarre grouping of cells called nodules.

Circulatory changes The circulation of the lobule has taken on marked changes. Due to the collapse of many sinusoids the portal blood supply is lowered. A compensatory increase in the hepatic blood flow occurs and we find the hepatic artery radicles becoming the main blood supply to the newly formed nodules.

Connective tissue growth There is a negligible amount of new connective tissue found in central necrosis even after the nodules are well-established. Studies by MacCallum⁵ and Beaver and Robertson⁶ showed that this existing tissue was with little exception the original stroma.

Healed Stage

We now have a damaged liver with formation of nodules and a consequent change in the circulation. This stage is usually classified as healed toxic cirrhosis or healed yellow atrophy. Mallory considered this an end process and felt that it differed from progressive "alcoholic" cirrhosis. According to our accepted diagnostic criteria, however, healed toxic cirrhosis is indistinguishable from Laennec's cirrhosis. Toxic cirrhosis produces nodules and a change of architecture while Laennec's disease depends for its diagnosis on the same structural changes. Our studies lead us to believe that healed central necrosis, sometimes designated healed toxic cirrhosis, is the required preliminary damage to the liver in Laennec's cirrhosis.

Chronic Progressive Stage

Nevertheless, even if we accept toxic cirrhosis as the required preliminary damage to the liver, we must offer some explanation for its metamorphosis into chronic progressive cirrhosis. We must show some factor or factors that become active after

the original toxin has disappeared. Accordingly we note that either one or two factors may now add further injury to the damaged liver. An additional insult such as a return of the original toxin or the appearance of a new toxin, may occur, or, if no further scarring from toxins ensues, the time factor can come into play.

Precipitating factors Let us first consider the possibility of additional insults. Continued use of arsenic or cinchophen after clinical signs of liver damage is evident

Fig 3 Early central degeneration of the lobule in a case of biliary cirrhosis. This shows the possibility of central necrosis occurring in cases of biliary cirrhosis.

Fig 4 Early peripheral degeneration of a nodule, showing parenchymatous degeneration of the hepatic cells with infiltration by polynuclear cells and fibroblasts.

has been frequently quoted in the literature as a reason for toxic cirrhosis. Likewise renewing treatment in susceptible subjects is a well-known cause of subacute yellow atrophy. Again a different type of insult may ensue such as infectious hepatitis or bile-duct obstruction or even cardiac decompensation. Respiratory infections undoubtedly play a part. Some of these insults may be quite mild and not recognizable clinically. One must remember however, that it is generally accepted that hepatic toxins act with unusual severity on damaged livers. These cases of healed toxic cirrhosis that have escaped additional insults must confront the *time factor*. This is a variable but makes its appearance in the liver as a rule in the late forties or in the early fifties. We believe that it brings about changes in the liver, ordinarily of little significance, but markedly exaggerated when damage is present.

Shrinkage of the connective tissue If we take notice of the liver in the progressive stage of Laennec's cirrhosis we become aware of the activity of a number of non-toxic factors. The primary factor of the group is undoubtedly the shrinkage of the abnormally placed connective tissue. We are fully aware that shrinkage of the connective tissue occurs in injured livers. It seems to us that the activity depends largely on the degree of injury sustained. The greater the injury the greater the size and number of the nodules, and the more pronounced are the bands of collapsed stroma. In a number of our cases, recognizable severe hepatitis was followed shortly by advanced pathologic changes. We found the disease to move rapidly in continued or repeated injuries. Moon⁷ showed that in children it advanced very rapidly. Otherwise the progress of the disease took on a slow course.

By the connective tissue shrinkage important changes in the liver are brought about. The long held belief that it contracted down on the lobules and by pressure caused necrosis of the peripheral cells is now being discarded. We feel the same as Kelly,⁸ MacCallum,⁹ and Moon⁹ that the peripheral cells of the lobules or nodules showed no evidence of pressure atrophy, rather they were frequently large young healthy cells. Most of the evidence at hand points to the contraction being about the interlobular branches of the portal vein.

Change in the circulation As the shrinking connective tissue shuts down on the portal veins, the portal blood supply becomes gradually shut off. The hepatic artery radicles, probably because of their

thicker walls, are not affected. So we find a change in the ratio between the portal and the arterial blood supply. Normally the ratio is about seven parts of venous to three parts of arterial blood. Following a moderate case of toxic cirrhosis the ratio may be five to five and in the late cases of Laennec's disease, the supply may be almost entirely from the artery.

Change in the detoxifying function The change in the circulation within the liver is an important contributor to the progressive activity of Laennec's cirrhosis. Normally the parenchymal cells are bathed by the highly nutritive portal vein blood. As times goes on, however, more and more of them lose their connection with the portal vein and become dependent on the less nutritive hepatic artery blood.

By this change the nutrition of the parenchymal cell is altered. From our knowledge of the structure of the cell we would thereby expect a change in its functional ability. This can be shown to be true. It is not noticeable, however until the change has been great enough to pass the large safety reserve of the liver. Mann and his associates by means of an Eck fistula have shown that impairment of the circulation of the liver increases the effectiveness of many hepatic poisons in animals. They found that in dogs with Eck fistulas carbon tetrachloride was ten times as effective as similar doses in normals.

At this point we must give due consideration to the detoxifying function of the liver. It is undoubtedly one of the main functions of this organ and normally takes care of a large number of poisons that are either collected from the portal area or that get into the general blood system. We have just shown the change that comes in the detoxifying ability of the dog's liver following an Ecks fistula. We can see that the shutting off of the portal vein in man in cases of cirrhosis is a parallel condition. We are justified, then, in assuming that in cirrhosis the detoxifying function of the liver is lowered because the portal blood supply is below normal.

There is further evidence that the detoxifying ability of the liver is lowered in Laennec's cirrhosis. This evidence points toward a lowering of this function in some of the peripheral cells of the nodules. Turnbull and Worthington¹⁰ made serial sections of the nodules in this condition and concluded that circulatory conditions in the nodules tended toward inadequate nutrition in consequence of which the cells are susceptible to degeneration and fatty metamorphosis. They found that the nodules consisted of concentric rings of cell strands,

one or two cells wide, with intervening capillaries having their centers near the portal areas. They also noted that in the larger nodules the peripheral cells lacked all order and were served by branching capillaries usually tortuous, narrow, and difficult for the flow of blood. They saw many large cells in the nodules that gave positive evidence of fatty degeneration with Sudan III. There were in addition many cells transformed into signet ring forms and they found the cells furthest away from the center undergoing the greatest fatty metamorphosis. From this they concluded that the tendency to degeneration is expressed by a deficiency of large vessels and a faulty arrangement of the cell columns and capillaries in relation to those vessels.

Peripheral cell necrosis. The cell necrosis that occurs at the periphery of the nodule commonly found in active cirrhosis, is held by many to be the result of some infection. Inability to demonstrate bacteria in the liver, however, weakens this theory, while the fact that the liver is the detoxifying organ of the body gives weight to the theory that some toxin may be the cause. Furthermore an excess of toxin is the commonest form of liver injury, and expresses itself as an hepatic cell necrosis.

Assuming a toxin to be at fault we can accuse, as we have in the undamaged liver, a large variety of irritants singly or in multiple. We can also, with some rights, give consideration to the customary daily supply of toxins derived from the body metabolism. These endogenous by-products continue to be elaborated in the same quantities and strengths as when the liver was normal. At the same time the detoxifying function of the liver has been reduced to one half, one quarter or even one tenth of the normal. Hence the endogenous toxins automatically take on an exaggerated hepatotoxic role. Proof of this was presented by Mann when he showed a natural substance as protein to be detrimental to a dog's liver after an Ecks fistula, especially when there was no carbohydrate food given at the same time.

We agree with Moon⁹ that the cell injury preceded that of the neighborhood connective tissue reaction by some time. We feel that the presence of leukocytes may very well be attributed to the common occurrence of them in the liver following necrosis, and that the proliferation of the connective tissue cells is more than likely due to the stretching action following the influx of the leukocytes.

Parenchymal cell regeneration. Another important factor in the progressive stage of Laennec's cirrhosis is the liver's per-

sistent urge to keep up the original number of parenchymal cells. This urge is primal. It occurs even under the poorest conditions in the liver. Large healthy new cells are found in acute yellow atrophy, in the subacute form, in all stages of cirrhosis, and even in cancer. New cells are found at the periphery of the nodules in cirrhosis. It is our belief that these new cells follow in the same fashion as the new cells in the normal lobule, that is, they occur at the peripheral end of the cords. We also believe that they push the older cells toward the central vein as in the normal. But because the architecture in the lobule is abnormal, the older cells are pushed in abnormal directions governed by the amount of resistance. Conditions at times allow very large lobules to be formed. As the disease progresses, however, and the connective tissue becomes more constricted the regeneration is hampered and we now see the shrunken banded liver of the late stage.

Summary and Conclusions

After studying our cases we feel that Laennec's cirrhosis is not a specific disease entity. It seems to us that it could follow any one or any combination of liver damages provided necrosis of groups of parenchymal cells was followed by collapse of the lobule.

Because toxic cirrhosis usually causes a central necrosis with collapse of the lobule and permanent changes in the architecture, we feel that it is the common preliminary stage of Laennec's cirrhosis. Further evidence for this is that toxic cirrhosis constitutes by far the greatest group of acute liver lesions while Laennec's makes up the great majority of the chronic cases.

Finally we conclude that a group of factors, ordinarily nonpathogenic, become active months or even years after the liver is damaged and produces the later chronic progressive stage of Laennec's disease. We feel that the shrinkage of the abnormally situated connective tissue stroma is the initial factor in changing the healed toxic cirrhosis into the active progressive type. This in turn is a variable and is subject to a number of factors, chief of which are, the degree of injury sustained by the liver, the number of repeated insults, and the time factor.

Other nonpathogenic factors follow which assist in the progress of the condition. The changes in the circulation

from portal vein to hepatic artery supply, in association with the poor capillary bed in the nodules, leads to a lowering of the detoxifying threshold. Thereby a relative rise in the toxicity of the end products of the endogenous metabolism occurs which is followed by parenchymal necrosis. These dead cells acting as foreign bodies attract leukocytes which infiltrate about the necrotic areas causing edema and considerable stretching of the connective tissue. This in turn stimulates the neighborhood fibroblasts and new connective tissue is formed.

We believe then that Laennec's cirrhosis is the result of a group of factors, primarily nonpathogenic, which become

perverted after the liver has received a damage that causes the architecture on the lobules to be changed.

THE DREAM COME TRUE

An American dental surgeon, who has returned to this country after six years' practice in Palestine, tells a story that illustrates the mixed character of the Jewish population there. Some represent the highest education and culture, others the opposite. The doctor was a member of the dental staff of a hospital supported by the Hadassah. As told in the *Dental Outlook*, the account runs:

A middle-aged sun-bronzed Jew appeared at the clinic accompanied by an eight-year-old boy. The child presented a very swollen face on which at the site of the swelling was painted a vivid six-pointed Jewish star. Examination discovered a badly broken down upper first molar

The history disclosed that the child had had this condition of swelling for several months. Questioning further disclosed that the father believing that evil spirits had entered his son, had all this time offered up special prayers to drive them out. Failing in that, he had painted the star on the cheek, in the hope that that would exorcise them away. But the spirits persisted in dominating his son more and more completely. For the past few days the child had been in such pain, that nobody of the household could sleep. Then in a dream, an angel appeared to the father and told him that only at the hospital could the youngster again be purified. A forceps performed that sacred rite.

IF YE HAVE HEARTS, PREPARE TO PEEL THEM NOW

Peeling a patient's heart—removing inflamed portions of the membrane which surrounds it—is no longer a rare operation, though it is infrequently required.

This was the comment the other day of the medical information bureau, New York Academy of Medicine on the report from Milan, Italy, of a case in which the pericardium, or heart membrane, was peeled because it was hardened and swollen. The heart was bared by cutting the chest.

"In certain cases of pericarditis the membrane may become calcified, interfering with heart function," the medical bureau explained. Pericardial peeling has been done now for ten years or more."

The Milan operation was performed by Dr. Aldo Defrise and his patient was a fifty-two-year-old workman, who was able to return to his occupation after fifteen days.

Lifting out the heart, the surgeon found an inflamed and hardened membrane and a layer of fat an inch thick. In an eighty-minute operation under general anesthesia, he peeled off the diseased membrane.

The pericardium, or "sac" in which the heart lies, has a double layer of tissue, it was explained, with a lubricating fluid between. In case of inflammation, adhesions may result and sometimes calcium deposit, restricting the normal heart action.

PSYCHIC STATES ASSOCIATED WITH HYPERGLYCEMIA

EUGENE N BOUDREAU, M D, *Syracuse*

Thus far there is a dearth of literature upon the causative association of psychoses with hyperglycemia. Of course it has long been observed that sudden stupors occur in frank conditions of diabetes mellitus or since the discovery of insulin, with hypoglycemic states associated with hyper-insulinism. But thus far there have appeared in the literature few reports of cases of borderline diabetes or unsuspected cases of hyperglycemia and definite psychotic manifestations of either brief or prolonged duration which disappears with proper insulin-carbohydrate regime. My purpose in this contribution is to call attention to the probability of the fairly frequent occurrence of such states which may have a fatal issue unless recognized, which seem to be due to inadequate sugar metabolism or possibly combined with an inability of the kidneys to eliminate the products of a moderate inadequacy of sugar metabolism in some as yet unexplained pathological physiology.

For the present I can hope only to further arouse a medical interest and awareness of a problem by reporting three cases that have come under my observation, and by comments call attention perhaps to some aspects of them that need further understanding or definition. Additionally the prompt response of the conditions exemplified by these cases to insulin and regulated carbohydrate intake indicates a causative relation of the hyperglycemia and the psychotic state.

Let me, however, first refer briefly to the previous literature which has a relation to this matter. The first article which can be found bearing upon this subject was by Bond¹ in 1895. He noted the infrequency of glycosuria in older established cases of insanity. He gave results of urine studies in 175 recent admissions. Of these, twelve showed a glycosuria and most of these none of the chief signs of diabetes. Significantly he stated in this brief report, "In two melan-

cholia who recovered the improvement in their mental condition was coincident with the gradual disappearance of glycosuria." The next was by Hyslop² in 1907. In his article Hyslop refers to a paper read by Savage before the Medical Society of London in 1890, but apparently not published. Savage reported that in his observations, diabetes and insanity may alternate in families. One generation may be diabetic and the succeeding one insane and vice versa. He also reported that in individuals diabetes may give way to melancholia, to be again followed by diabetes. He referred to ten of his own patients who were diabetic and insane and confined at Bethlem.

Hyslop in his article also reported his own observations and then classified such related cases as follows:

- 1 Alternating types—cases of melancholia in which diabetes is an incident, and cases of diabetes in which melancholia is an incident

- 2 Dementia in relation to diabetes succeeding repeated psychic shocks, albuminuria, vascular degeneration, and renal disease

- 3 A type simulating general paralysis of the insane

- 4 Cases in which the metabolic defects are attended by confusion of the mental faculties and delusions

- 5 One case which presented a clinical picture of pseudotabes

- 6 Mania with temporary glycosuria

- 7 A psychopathic temperament in the offspring of a diabetic parent

- 8 Cases in which paralyzes are a prelude to diabetic uremia and coma.

Nothing further appeared in the literature until 1917 when Singer³ published his paper. He stated in substance that there is no characteristic mental picture associated with diabetes mellitus and also called attention to the fact that the type of mental state common to "brain intoxications" of all kinds is the so-called toxic hallucinosis "with which may be asso-

*Read at the Annual Meeting of the Medical Society of the State of New York
Rochester, May 26, 1937*

ciated clouding of consciousness" He also presented reports of two cases which tended to show that with a diminution of glycosuria there was an appearance of toxic symptoms He likewise noted increasing evidence of parenchymatous changes in the kidneys in one of his cases Apologetically he commented that no blood chemistry studies were made in his cases Parenthetically I may say here that these two cases may have been similar in type to the cases I am reporting

In 1921, Pike⁴ presented a case illustrating the etiological relation of glycosuria (he presented only urinary findings) to a case of depression

Katz⁵ (1934) presented a case before the New York Academy of Medicine in which a catatonic syndrome appeared in a young woman with diabetes which cleared away as the diabetes was controlled by a proper carbohydrate, fat, and insulin balance She was discharged as cured

At the same meeting Harris⁶ discussing the "Metabolic Considerations Regarding Diabetic Psychoses," pointed out the ability of the brain to utilize carbohydrates and that it used this source mainly for its needs On this basis he was disinclined to believe that a psychosis could be caused by mild conditions of diabetes or hyperglycemia although he was willing to admit that they might occur in longstanding diabetic states of severe character or degree In such instances his thought was that the by-products of the disturbed physiology in such a person accounted in part for the mental disorder

Dr Cheney in discussing both of the papers pointed out the possible relationship between the acute onset of the stuporous state and the emotional reactions of having seen an exciting movie a few hours before He stated also the belief in the infrequent appearance of mental disorders caused by hyperglycemia He said on that occasion that he did not think there is at present a characteristic diabetic psychosis

In 1935, Menninger⁷ presented a complete analysis of the subject with illustrative cases which has illuminated it more thoroughly than any discussion previously appearing in the literature In his series of cases, thirty were of mental

disorders associated with diabetes Of these, three were classed as mental disorders caused by diabetes and were similar to those here presented

Therefore, in summing up the literature published in English there appears, so far as I could find, nine previous cases in which there seems justifiable causal relationship between diabetes and abnormal psychic states To these I would add three

The first two have been previously reported between 1933 and 1934 before local medical groups The third has not been reported before This case, I regret, has inadequate data because of the difficulties surrounding its study

CASE 1 Mrs E M P, aged fifty-three, married Her father and mother both died of diabetes According to her statement, the members of her family were excessive eaters She was the only survivor of four children, the other three having died in childhood An uncle on her father's side died of paresis She was a pampered child, at the age of twelve she had acute chorea, and never returned to school She lived at home until her marriage at the age of thirty-one Relative to personality traits, she was happy, sunny, alert, and efficient Her married life was happy, but she had no children At the age of thirty-eight, in 1916, she had developed diabetes From 1929, it had been noticed that she was not mentally up to normal, this was most noticeable in a lack of ability to concentrate and a tendency to change abruptly from one task to another In July 1931, she had suffered from uterine hemorrhages, and had been sent to a general hospital in her home city for x-ray treatment to control the condition She had become extremely cross and irritable, so that it was difficult to keep nurses in attendance On August 3, after her return home, she suffered a spasm of the left face, and following this showed a mild paresis of the left arm and hand She became restless and confused, she was in bed three weeks, during which time she was depressed and developed delusional ideas relative to her husband and her nurse This state continued, with moderate remissions, to November, when there was a more pronounced remission, and she was again able to drive her car when accompanied by her husband On Thanksgiving Day, however, she again began to be more restless, depressed, and emotional, with no apparent reason, and was somewhat disoriented with regard to persons and places She was referred to Twin Elms by her physician, Dr

D D O'Brien, on December 1 The physicians certificate describes her condition at that time as follows

She is not acutely ill, is sitting restlessly in a chair. Eyes show slight irregularity of the pupils, both react normally, movements normal. Face normal, cranials negative, heart normal, blood pressure 185/90, lungs normal, abdomen, pronounced visceroptosis. Deep reflexes right normal, left hyperactive, slight ankle clonus, no Babinski. Suggestive weakness of left hand and leg, slight drag of the leg (cooperation poor). Pulse 98, temperature 98° F, respiration 24

Crying almost constantly, confused, apprehensive, clouded, very restless, depressed, disoriented, seems under great mental tension and fear, slight agitation. Inclined to be a little resistive and disturbed. Completely out of contact with reality. Answers questions incompletely, irrelevantly, and erroneously. Wanders aimlessly if not watched, needs constant supervision, misidentifies people, accuses people of being mean to her, claims that those about her are assaulting her.

She said in the presence of the physician "I may as well give up, I don't see any chance of getting well. Believe me, your daughter is an awfully impertinent girl. Dr O'Brien brought me here because he said I wasn't worried. I am crying because I want to. I don't know why I'll see Dr G just as soon as I possibly can. I am 36 years old. I was born in '36, my husband is 37. Doctor, I've certainly been very unhappy." [Report by] L.J.B.

After admission the patient continued in the same toxic, confused mental state. The physical signs were as noted above, except that the blood pressure once reached 210/98. Laboratory reports, under date of December 2, were as follows

N.P.N. 38 mgs per 100 c.c. of blood
Blood sugar 250 mgs per 100 c.c. of blood.
Urine clear, amber, acid, 1025, albumen 3, sugar 2, rare hyaline casts
Blood Wassermann negative with both antigens

As the ordinary dietary measures and the usual amount of insulin, which were employed at first, proved inadequate to correct the metabolic defect, Dr William A Groat was called in consultation (December 9). He increased the insulin to 110 units per twenty-four hours, and suggested an increase in carbohydrate intake. Under this regime the sugar, diacetic acid, and acetone disappeared from the urine in a predominant number of specimens (the urine was examined three times daily). The patient's mental state continued with little change until December 18, when there followed an improvement which progressed slowly for another period of three weeks. Finally after January 1, 1932, the improvement became more rapid, and the patient

was discharged on January 10. At that time she was entirely clear mentally, and had apparently nearly reached a normal level of mental state. The neurological signs had likewise disappeared. The patient returned to her home, accompanied by a nurse, and there her condition continued satisfactory.

To the time of her death from pneumonia, she remained in a normal state, by following the prescribed diet and using moderate amounts of insulin.

CASE 2 Mrs A.L., aged sixty-five, widow, was born in the United States of cultured parents. Married, widowed, no children. Fractured right arm twenty-three years ago. Had a lump removed from the left breast ten years ago. Had a "mild diabetes" for four years previous to the present illness. She had been an active, competent person, supporting herself during widowhood in a business position. For diversion, she continued an early interest in classic literature.

Family history. Father died at 63, collapsed during an operation for stone in the bladder. Mother, who had been diabetic for four years, died of pneumonia in 1931, aged eighty-four. Three brothers living and well, one of these, however, showed evidences of diabetes three years previously. One brother was murdered by highwaymen many years ago. One sister living, very deaf since a fall from a street car many years ago.

Present illness. On October 11, 1931, the patient fell upon the street, fracturing the neck of the left femur. She was taken immediately to the Syracuse Memorial Hospital, where a plaster-of-Paris cast was applied. She endured the misery of confinement serenely and optimistically for weeks, or until about time for removal of the cast, diverting herself by continual reading and embroidering.

At the beginning, because of the "mild diabetic state," she was cautiously dieted. After October 13, she excreted no sugar in the urine (Table I). On January 26, 1932, the nurses' notes state that she was "a little irrational," and on January 30, that she "was moving about restlessly, regardless of the injured leg." The cast was removed on February 1, the nurses noting that she was "crying, removing the bed clothes, asking for her mother, restless, and would not eat." The writer saw her, in consultation with Dr R L Leverton, on February 4. She was then in a deep stupor. The note made at that time in her hospital record reads as follows: "The history here obtained by close questioning is of the rapid onset of a mental clouding which has progressed

to complete stupor" There were no abnormal neurological findings. A toxic state was suspected, and further blood chemistry studies suggested. The subsequent laboratory picture also is shown in Table II. It will be noted that on February 4, although there was no sugar in the urine, the blood sugar was 234 mgs to 100 cc of blood. Five

again asked to see her, as the clouded mental state had recurred and she had become so stuporous that no food could be given in the ordinary manner. Gavage was resorted to, of a prescribed diet. With each feeding twenty units of insulin were administered. After this, consciousness returned shortly and she soon began taking food voluntarily. Insulin was then given as follows: February 25, units 20, 10, 20, increased on February 27 to 20, 15, 20.

On March 3, the patient was admitted to Twin Elms on voluntary application, on account of her physically crippled state and because an occasional moment of mild confusion had been noted. She also was in a very uncomfortable state of physical restlessness. This was soon relieved by hydrotherapy, and she rapidly returned to a normal state. In the weeks that intervened before her discharge on May 31, she learned to use first crutches and then a cane, and afterward made the journey to her brother's home in the South unaccompanied. After that time she had remained normal mentally, although she was obliged to undergo an operation, a breast amputation, on a moderate food and insulin regime. She finally died of carcinoma.

CASE 3 Mrs. R.A., aged sixty-two, Jewish, married, was first seen at Crouse Irving Hospital with Dr. Burton Doust, October 20, 1935.

Family history Negative for mental diseases.

Past history A hysterectomy done twenty years previously. Suffered a facial paralysis seven years previously, but fully recovered. Was always "nervous" and had a "bad throat." She had had sugar in the urine for three or four years.

Present illness began in April 1935. She became nervous, lost weight, had a cough that lasted three weeks, a heavy feeling in the lower axilla, pain in the back and neck, weak and tired all of the time, and mentally depressed. However, she continued at home until October 8, twelve days before I saw her. She had been admitted for physical checkup.

The physical examination by Dr. Doust on admission to the hospital was reported as follows:

Blood pressure 190/90 Temperature 99
Pulse 88 Weight 120 lbs Heart enlarged to the left. Sounds of fair quality. There were fine crackling rales at both apices. No dullness nor bronchial breathing. Abdomen negative.

I was requested to see her because of the recent onset of disordered behavior. She had become confused and hard to manage.

units insulin, t i d was increased to ten units t i d. As the blood sugar decreased, there was a parallel improvement in the mental state, but the patient developed a moderate respiratory infection and showed elevation of temperature for several days. She was seen by Dr. W. A. Groat on February 17, who suggested a dietary regime of C-120, P-60 and F-100. On February 19, Dr. Groat and the writer were

in a general hospital. She had to be constantly attended because she continually tried to get out of the room, apparently seeking to get home, although she did not know where she was. Now and then she was noisy. On the 18th, two days previously, she showed slight elevation of temperature following a clysis, but this quickly subsided. Following this she had shown some moisture in her lungs for two days, but on the morning of my examination this had gone and her general physical signs were normal.

My neurological examination was negative. Mentally she showed no trends nor hallucinatory evidences, but was quite completely disoriented in all spheres. She was restless, talked of wanting to get out of the place and go home.

The laboratory findings up to that time and subsequently, showed abnormalities only in the urine and blood as follows:

Urine October 9 to 25 showed sugar reduction varying from 3+ to 5+. Specific gravity up to 1030. Frequently there was a trace of albumen. Acetone rare.

Blood Sugar October 9, 266, October 18, 266, October 21, 381.

After I saw her, Dr W A Groat was called in to advise upon dietary and insulin schedule. There was considerable difficulty in following this because she resisted food. However, this was managed sufficiently well so that by October 26 she was permitted to go home, improved but still clouded. At intervals from then she was cared for by Dr Leon Goldstein who was given charge in the absence of the other physicians. Her mental state rapidly cleared and remained so through the succeeding months to her death of pulmonary tuberculosis, November 2, 1936.

Laboratory reports continued to show presence of sugar in the urine from 1+ to 4+. Blood sugar on December 15, 1935, was 194 mgs. There were no laboratory reports after that date.

By way of comment, I would say that these three cases I believe carry further strong evidence that severe and prolonged psychotic states of potentially fatal outcome are associated with defects in sugar metabolism and hyperglycemia. These psychotic states may appear when there is no glycosuria present, and seem perhaps to be related to defects in the functioning of the kidneys. These abnormal mental states are toxic in type, and conclusively disappear with the removal of the hyperglycemia.

Aside from the positive conclusion just drawn there are additional unexplained

conditions that can be pointed out as we consider these cases. I can venture no explanations myself, but leave them for the physiologist or the physiological chemist.

Therefore, these questions can be raised to be later adequately explained.

1 Why should one person with only slight evidence of hyperglycemia or a hyperglycemia of a relatively moderate degree suddenly present toxic mental symptoms lasting over a protracted period and yet another person showing a hyperglycemia amounting to three, four, or even five hundred mgs of blood sugar in a hundred cc of blood show none?

2 Can we not raise the question of whether in some cases of hyperglycemia there are other associated toxic substances present, but not shown by present laboratory methods, or that are not present in all cases of hyperglycemia? Or perhaps it could be put in another way—may not other substances than sugars produce reduction in our present reducing method for the detection of sugars?

3 If so, what is the character of such substances that may so change the normal physiological cerebral processes as to produce the reactions exemplified in these three cases?

4 Can there be any correlation between the physiological conditions here exemplified and the physiological conditions of profound hyperinsulinism currently used to combat mental disorders?

5 Does the hyperglycemia produce a changed osmotic relationship and a hyperconcentration of water in the nervous elements?

6 In the study of future cases, should not these following relationships be correlated: intake of fluids and output of urine, blood concentration, ratio of sugar and NPN in the blood, blood cell relationship and character, and respiratory quotients?

Summary

Abnormal mental conditions have long been noted in connection with diabetic or hyperglycemic states. Nine cases apparently causally related to hyperglycemia have been collected from the literature. One of the writers has called attention to the appearance of a toxic mental state associated with a diminishing glycosuria, and observed some associated parenchymatous kidney damage in one of his cases.

The three cases here added illustrate a toxic mental state or state of mental confusion, associated with a hyperglycemia.

All of the cases recovered from the mental condition when the hyperglycemia was removed. Case 1 showed additionally delusions and focal neurological signs. This case also showed glycosuria during the psychosis, but in Case 2, glycosuria was rare. Each case showed kidney impairment.

Whatever the physiological explanation of these states may be, it is apparent that severe mental disorders, possibly progressing to a fatal outcome, may occur in moderate diabetic conditions without the presence of sugar in the urine. Careful laboratory investigations reveal the source of the disaster, and the administration of larger quantities of carbohydrates, together with the necessary amounts of insulin to assure their metabolism, removes the causative agents. It is therefore, important to be on the alert to recognize these conditions as otherwise many of them may escape detection with a resulting fatal issue.

Conclusions

1 Hyperglycemia over a comparatively short period may be followed by a prolonged clouded mental state, with or

without delusions. This state has the qualities of a psychosis.

2 Hyperglycemia and an associated acidosis or ketosis may be present and produce such mental states without the urinary findings giving evidence of the hyperglycemic condition. Blood sugar, however, is high. In such cases the other urinary findings suggest kidney damage, and possibly an elevated kidney threshold for sugar.

3 Such "toxic" mental states seem to be independent of personality traits or inherent family tendencies, and to be caused by a state of hyperglycemia.

4 These mental disorders promptly respond to removal of the hyperglycemia by the administration of insulin and a proper dietary regime.

Discussion

DR A. G. ODELL, *Clifton Springs*—Dr Boudreau's paper sets before us some interesting questions and opens a field deserving of further study.

In the three cases presented, one common condition seems to be present—all were toxic from some cause. Dr Boudreau feels that a hyperglycemia was the sole cause of the toxicity in each. Yet in all three, there were evidences of damaged renal function, aside from the presence or absence of a glycosuria. One must keep in mind that glycosuria is not an evidence of damaged kidney structure, but rather an evidence that the sugar has risen above the threshold of the blood and is spilling over into the urine. It is an evidence of an inability of the body to utilize properly the amount of carbohydrate taken by the individual. It should also be kept in mind that the internist sees many persons with a marked hyperglycemia and no glycosuria.

In the first case a definite cerebral accident occurred and all three seem to show more or less arteriosclerosis. Does he feel that the relation of impaired renal function, damaged cerebral structure and arteriosclerosis were thoroughly ruled out in each case?

Again no note was made as to the bromide content of the blood. Was it measured? One of the first things given by many physicians in cases of restlessness is bromide. A symptom of bromide intoxication is mental confusion. An increasing number of patients with mild confusional state have been coming to my attention with blood bromide ranging from 78 to 175 or more. They promptly clear up when put on an adequate amount of sodium chloride. Had any bromide been given his patients before he saw them? If so, how much and for how long?

Another point is the rarity of such states when compared to the great number of pre-diabetic and diabetic patients we see each year. From January 1, 1933 to May 20, 1937, there were admitted to the Clinic with which I am associated, a total of 242 patients in whom a diagnosis of hyperglycemia was made. This means that in this group of patients there appeared a temporary hyperglycemia, not severe enough to be called a true diabetes and one which yielded readily to a rearrangement of diet. Of these, thirty-one (12.8%) showed a neurologic or psychiatric condition. And of this thirty-one, only two had a psychosis—manic-de-

pressive psychosis accounted for one and catatonic precox the other. None of the thirty-one showed any confusional state. Apparently no connection between the hyperglycemia, the anxieties, depression, encephalitis, etc. was noted. The increase in blood sugar was picked up incidentally in the course of an examination which included a study of the blood sugar, urea nitrogen, and Wassermann reaction. This study now includes the bromide content. Comparatively few showed any continued glycosuria or in fact any glycosuria at all.

Of the hyperglycemics severe enough to be diagnosed diabetes mellitus, a total of 361 were admitted from January 1, 1935 to May 20, 1937. Of these, only three showed enough to warrant a diagnosis of a psychiatric condition—anxiety neurosis, neuropathic personality, and an agitated depression in a senile individual. Again no confusional states. Of course, this may be due to the fact that we admit no frank psychoses, but is it not strange that no mild confusional states should appear in these 603 patients? It would seem then that a confusional state directly due to a hyperglycemia is very rare, to say the least. Before hyperglycemia is indicted as the sole cause, every other possible source of toxicity should be ruled out of the picture.

Dr Boudreau has raised some interesting questions. Anent his first one, what causes the toxic state in uremia? Why does one person with a badly damaged kidney develop this state and another with almost exactly the same damage not develop uremia? Why does one woman develop a postpartum mental state and hundreds of other women do not? Why does one cardiac patient have the added burden of mental symptoms while others with the same condition do not? His question and these similar ones may sometime be found to have the same answer.

Is there some other reducing substance in the blood beside sugar? A biochemist just this morning made the statement that the newer methods measure sugar only and that if there was any question, a fermentation test similar to the urine fermentation test would settle the question.

If there are other toxic substances present and if these cause the mental state Dr Boudreau describes, why do so very few (only at best twelve reported cases) of the large number of hyperglycemic patients develop this state?

Suggestions were given as to certain blood studies to be included in the examination of psychotic patients. Should not bromide be added to the list? This question is asked because of the very free use of bromide in proprietary preparations (Nervine, Bromo-Seltzer and the like). All these are easily

obtained and too freely used by the general public.

The absence of urine sugar in the presence of a high blood sugar has already been discussed.

Much as I should like to agree with my friend, Dr Boudreau, I cannot feel that the hyperglycemia was the sole cause of the states described.

He has, however, given us something to think about and for which we should be on the lookout.

DR GEORGE E DANIELS, *New York City*—It has been a privilege to read and study Dr Boudreau's interesting communication and to have the opportunity of discussing a few of the stimulating questions which it raises. The paper is not only timely in inquiring into the still little understood relationship between carbohydrate metabolism and mental disease, but also in calling the profession's attention to a clinical entity which, if not recognized and properly treated, is likely to end in lethal issue. As Dr Boudreau points out, the literature is all too sparse in such case reports.

My own experience with the problem of diabetes and psychic states comes chiefly from an approach other than that furnished by patients encountered in mental hospitals. For the last two years some of my colleagues and I have had the opportunity of examining psychiatrically routine admissions to the Metabolism Ward and Out-Patient Department of the Presbyterian Hospital, New York City. The results of the first year's study have been published in a recent issue of the *American Journal of Psychiatry* (November 1936). In addition, I have seen cases of diabetes referred for consultation on specific psychiatric problems. I do not remember having seen just the type reported by Dr Boudreau which is of particular interest on account of the special toxic features.

Dr Boudreau raises the question of a characteristic mental picture in hyperglycemia and quotes several authorities who question whether any such has been discovered. My own impression coincides with this, and I am still looking for a clinical case whose psychic symptoms can be explained entirely on the basis of a high blood sugar. Various clinicians, as well as patients whom I have questioned, mention depression as the most frequent manifestation. Dr Boudreau has quoted pertinent literature on the subject of diabetes and melancholia, and it is of interest that two of his own cases showed depression as a prodromal symptom.

In twenty-three cases reported by me, ten had shown noticeable depressions associated with their diabetes. A striking finding in

five was that diabetes had been discovered during depressions reactive to the loss of a person to whom they had had a strong emotional attachment, or such a loss had occurred just prior to appearance of sugar and was of apparent significance for the depressive picture appearing during the disease. Fluctuations in the sugar level of diabetics from emotional causes is an established fact. In relation to psychoses associated with hyperglycemia, one must ask how much of the picture appearing is of emotional or psychic origin and even question how much the high sugar level causing the toxic feature may not have its source in a disturbed emotional life.

The case reported by Dr Katz and cited by Dr Boudreau illustrates how complicated such a problem is. I saw this case shortly after she was admitted to the Presbyterian Hospital. She presented the picture of an acute schizophrenic episode. A note by the internist who had followed the case for three years previous to admission laid stress on her marked feelings of inferiority and severe depressions over the problem of masturbation. He repeated the familiar statement regarding the rarity of psychic changes encountered from high blood sugar alone and considered the case a striking example of how a psychosis can disturb carbohydrate metabolism. Dr Cheney's remarks regarding the movie which the patient had attended were particularly pertinent in view of the fact that the subject of the picture, "When Life Begins," mobilized her fears of pregnancy to which she had been recently exposed. Every psychiatrist is acquainted with psychoses which have been precipitated during or immediately after attendance at the theatre.

I could not entirely agree, therefore, that psychotic pictures appearing with hyperglycemia are independent of personality traits even though the clinical picture gave evidence of toxemia.

I can do little more than raise further speculations concerning the far-reaching question which Dr Boudreau raises at the end of his paper. The question why some hyperglycemics show psychic manifestations and others do not, is especially interesting. Physicians who see diabetics in practice are more acquainted with mental changes in hypoglycemia or insulin "shock," and there is a question whether even at high sugar levels some of these shock-like reactions do not occur. Dr Boudreau's question of some special toxic substance in certain cases and the need of careful checks on kidney function are pertinent. The whole relation of the subject to current hyperglycemic therapy in schizophrenia is an inviting topic, the explanation of which faces both Psychiatry and Medicine as a challenge to a further understanding of the biologic basis of neurosis.

DR NOBLE R CHAMBERS, *Syracuse*—Dr Boudreau's presentation impresses me as being particularly important at this time when we are hearing so much of hypoglycemia and dementia precox. It is interesting to note that epilepsy is extremely rare in diabetics, in which, of course, we are dealing with hyperglycemia. Dr Joslyn once told me that epilepsy is almost unheard of in diabetics. Are blood sugar, ketogenic diet, restriction of fluids, water balance related? I am wondering whether the hyperglycemia described by Dr Boudreau could possibly be attributed to the emotional status of the patient and perhaps be the result rather than the cause of the psychosis. Unless I am mistaken blood studies in the so-called functional psychoses have failed to reveal any marked deviation from the normal. I think Dr Boudreau is to be congratulated for his presentation of three interesting cases in which, whether cause or result, hyperglycemia was associated with psychosis and apparently improved following attention to their hypoglycemia.

A WORD TO THE YOUNG DOCTOR

The young physician's career, especially in a small community, may be blighted for many years by the unfortunate outcome of a prominent case. The moral is that it is wise for the young and inexperienced man, especially the young surgeon, to avoid the heavy responsibility of a case in which the outlook is definitely bad. It is better to show caution and call in a more experienced man whose reputation can better stand the strain of a fatality. Do not hesitate to call for consultations. It is

not a sign of weakness or lack of courage, but is a sign of prudence and wisdom and often moral courage, which is appreciated by the laity. Never object to the calling of a consultant when asked for by the family, even when it seems entirely superfluous. Objection on the part of the attending doctor leads to all kinds of suspicions, and if matters take a turn for the worse later on, the objector is put in a very unfavorable light—*Lincoln Davis, M D, Boston*

CONGENITAL SYPHILIS

A Three Year Survey in Syracuse

C GEORGE MURDOCK, M D, *Syracuse*

The recent attacks on syphilis made by Dr Thomas Parran of the United States Public Health Service and by the New York State Department of Health have been most ably supported by the press and public opinion. It would, therefore, seem timely for us, as pediatricians, to review and perhaps renew interest in the role we may play in the onslaught upon this dread disease. The pediatrician only too frequently sees the ravages of syphilis in the newborn or small child which could have been prevented or lessened by the cooperation of the mother or of the obstetrician at the time of the mother's pregnancy. For practitioners in a field of medicine which is largely aimed at prevention, congenital syphilis offers a golden opportunity because here is a disease which could be almost totally eradicated. Let us strive then not only to treat and attempt cure in the already blighted child, but also by our associations, both public and professional, to encourage the diagnosis and treatment of prenatal syphilis. We have laws in this State regulating the transmission of most infectious diseases such as scarlet fever and diphtheria. Why not a law requiring routine Wassermann tests early in pregnancy and enforced treatment of all positive reactors during pregnancy?

Investigation into the medical literature in the preparation of this paper reveals the regrettable fact that there have been very few surveys made regarding the incidence of congenital syphilis. No figures are available on the incidence of this disease in the United States or foreign countries for the country as a whole. The United States Public Health Service Statistics and those published by the League of Nations give no separate figures for congenital syphilis. The studies which

have been made deal only with various hospitals, clinics or geographic subdivisions. Because we do not know how much congenital and prenatal syphilis exists and has existed, we are unable to determine our progress in the eradication of this disease. Most previous surveys have also tended to be misleading because they have covered, with few exceptions, only the lower social classes where the incidence of congenital syphilis would obviously be higher. They have not shown the incidence of this disease in the middle and upper social classes.

Table I shows the incidence of positive Wassermann reactions in pregnant mothers seen in the prenatal clinics of Syracuse for the past seven years. It is of significance to note that the percentage for 1936 is appreciably higher than that of any preceding year. A Wassermann is taken routinely on all patients admitted to these clinics.

In Table II the cases for the past three years with positive Wassermanns have been classified as to the presence or absence of the disease in their offspring. Unfortunately no follow-up work was done on the babies born before 1934 so that an analysis of the cases prior to this time was impossible.

The Wassermann reactions referred to in this and the following tables were taken on the babies three and six months after birth. Without exception, the cases that aborted, delivered still-births or delivered babies with congenital syphilis, were mothers who either refused treatment entirely, were not treated regularly during their pregnancy, or were not seen at the clinic until very late in their pregnancy. The group whose babies showed negative Wassermanns were mothers who had come to the clinics early and had received treatment regularly throughout their pregnancy. The group described as syphilitic babies were those that showed positive signs of syphilitic in-

I wish to thank the Bureau of Social Hygiene of the Syracuse Department of Health and the various private practitioners of Syracuse who have made the preparation of this material possible.¹

Wassermanns or positive Wassermanns with no other signs or symptoms of syphilis. All the physicians in this group replied in the affirmative when asked if they took routine Wassermanns upon all their cases.

Table IV shows an analysis of maternity cases treated by general practitioners. It does not include all the general practitioners in Syracuse, but an effort was made to include those men doing the bulk of the obstetrical work. It is of interest to note here that four of the ten physicians reporting do not take routine Wassermanns upon their cases. We can surmise that more syphilitic cases might have been found if these physicians had taken routine Wassermanns.

Table V is an analysis of the percentage of syphilitic pregnancies in the various groups for a three year period from 1934 to 1937. As might be expected the clinic cases show the highest percentage. The incidence among the cases seen by the general practitioner is high enough to warrant the taking of routine Wassermanns, and the obstetrical specialist should not overlook the Wassermann test in the routine care of his patients.

Table VI is a compilation of studies made during the last two decades of the incidence of congenital syphilis in various

clinics and hospitals.²⁻⁵ It is again important to stress the fact that most of these figures were compiled from the lower strata and, with but few exceptions, no allowances made for miscarriages or stillbirths due to syphilis.

Summary

A survey of the City of Syracuse reveals a tendency to a higher incidence of congenital syphilis in the lower social strata.

Congenital syphilis is still to be found among the upper social strata.

Routine Wassermanns should be taken early on all pregnant mothers and vigorous antiluetic treatment instituted early by the attending obstetrician when indicated.

Infants born of syphilitic mothers should be frequently checked by physical examination and Wassermann tests for signs of the disease.

WARNING AGAINST MEDICAL STUDY IN EUROPE

American youths planning to study medicine in Europe were warned against enrolling in inferior continental schools by Dr. Lester Samuels, superintendent of the Van Wyck Hospital, Jamaica, upon his arrival home recently on the Queen Mary after a month in France and England.

Dr. Samuels was a delegate of the American Hospital Association to an international medical convention in Paris and also studied England's national health insurance plan in London, Manchester, and Leeds Hospitals.

Alarmed at the influx of Americans into her medical schools, England is cutting down the numbers of foreign students, Dr. Samuels declared.

"Many Americans, unable to gain admittance to American schools, have gone to England to study," the doctor said. "Now that English schools are closing their doors to foreigners, these students will go to inferior continental schools to study. This

is a grave error, for many of these schools do not give adequate training, approved by New York medical authorities, and as a result, graduates are barred from examination in this state."

As an example of England's new policy Dr. Samuels cited the Royal College of Surgeons, of which he is a graduate. The college in the past two years received 1,700 American applications, of which six were accepted. Other colleges have had an American enrollment of twenty to thirty per cent, he added.

The practice of established American doctors going to Europe to study also was deplored by Dr. Samuels, who holds American schools superior to any in Europe.

"We are ten years ahead of Europe in surgery," he said. "Many postgraduate schools in Europe are purely commercialized propositions. Our doctors will do better to stay at home and study at our excellent American schools."

CORONARY THROMBOSIS

Relationship to Thromboangitis Obliterans

MEYER SCLAR, M D, *Brooklyn*

Associate Attending in Medicine and Cardiology, Kings County Hospital

When one considers the fact that it is less than twenty years, since coronary thrombosis has been recognized as a distinct clinical and pathological entity, it is not surprising, that thromboangitis obliterans of the coronary arteries was not definitely proven histologically until 1936

It is true that in 1918 Levine and Tranter¹ published a report of two cases of coronary thrombosis, one of which, was diagnosed antemortem, and Pardee² in 1920 discovered the characteristic electrocardiographic changes following an attack of coronary closure, yet Sir James MacKenzie,³ in his last work on angina pectoris published in 1924, never made the clinical distinction between angina pectoris and coronary thrombosis

Buerger,⁴ in the same year, concluded that thromboangitis obliterans did not involve the blood vessels of the viscera, probably due to the fact that in all his five hundred cases, he had available only four autopsied—the remainder was largely limited to surgical specimens, either biopsies or amputations. These four autopsies revealed three with thrombosis of the visceral arteries—one with thrombosis of the left anterior descending coronary in a man, twenty-four years of age, in whom histologic studies established the presence of arteriosclerosis. It is an unusual age for arteriosclerosis and when one considers the fact that this young man suffered from thromboangitis obliterans of both lower extremities for four years, the association between both conditions takes on added significance

Perla,⁵ in 1925, reported a case of thrombosis of the left coronary artery in a forty-four year old male with an organized and canalized thrombus occluding this artery for a distance of 1.5 cm. Because these changes resembled those seen in thromboangitis obliterans of the extremities, he felt that the process must have been one and the same

In 1929, Allen and Willius,⁶ in a series of 225 patients with thromboangitis obliterans, at the Mayo Clinic, found only

seven of coronary artery disease, clinically diagnosed. They concluded the following "the incidence of disease of the coronary artery in this condition as it occurred in our experience is probably not materially greater than the association with other diseases in the same age group"

In the same year, Barron and Linenthal⁷ after a study of thirty-four cases of thromboangitis obliterans, twenty-seven of their own and seven from a review of the literature, arrived at the conclusion "that this disease is not confined to vessels of the extremities but is a generalized disease that may affect any part of the arterial tree, including the coronary arteries"

In 1930, Samuels and Feinberg,⁸ in a study of fifty cases of thromboangitis obliterans with reference to coronary artery involvement, found "that only five of these cases showed definite clinical and electrocardiographic evidence of myocardial damage—presumably due to coronary artery lesions"

In 1932, Brofeldt⁹ described a case of Buerger's disease in a man of sixty-five, where autopsy showed a thromboangitis obliterans of the abdominal aorta

In 1934, Averbruck and Silbert,¹⁰ while reporting the cause of death in forty-seven cases of thromboangitis obliterans, found that twenty-two died as a result of some visceral vascular accident. In thirteen, the diagnosis of disease, or thrombosis, of the coronary arteries was made during life, with five proven by autopsy. They conclude that "there is more than a casual association between sclerosis and thrombosis of the coronary artery, and thromboangitis obliterans of the vessels of the extremities". Yet, despite this observation, they go on to state "that as pathologic studies fail to establish the diagnosis of thromboangitis obliterans in the vessels of the thoracic and abdominal organs the acceptance of the occurrence of the disease in these organs for the time being must be presumptive". Therefore,

they find it difficult to agree with Barron and Linenthal's⁷ conclusions "that thromboangitis obliterans may involve any part of the arterial tree," contending that as yet there was no clear evidence for this view.

In 1935, Telford and Stopford¹¹ described thromboangitis obliterans of the coronaries in a twenty-six year old male. They did not, however, report sufficient histologic studies to make this diagnosis a certainty.

In 1936, Eppinger¹² reported a case of thromboangitis obliterans involving both lower extremities in a forty-three year old male with extensive distribution of the vascular lesions including the coronary arteries. Though he states "that on autopsy, the most unusual and remarkable finding was the thrombosis with canalization of the larger coronary arteries," he is nevertheless in doubt as to the true nature of the occluding process, because he subsequently states "that the tendency of these blood vessel lesions at certain stages of their development, to have histological as well as clinical similarities, makes the designation of a specific type a much mooted problem."

In the same year, Mallory¹³ published a case of acute thromboangitis obliterans of the coronary artery, proven histologically, in a fifty year old male, English-Irish parentage, with a history of Buerger's disease of two year's duration. He concludes "that thrombotic occlusion of visceral arteries occurs with too great frequency in this disease to be purely coincidental."

Some nine months later, Saphir,¹⁴ after detailed anatomic and histologic studies, reported a case of acute thromboangitis obliterans of the coronary arteries in a thirty-five year old male who was known to have the characteristic symptoms of Buerger's disease for a period of about six years.

Averbrück and Silbert¹⁰ found that 38.3 per cent of their series "died as a result of what can be suspected clinically to be disease of the coronary artery." The same authors also state that "Until the pathologic process of vascular disease in general receives more detailed description and classification, the diagnosis of thromboangitis obliterans in the visceral vessels will be a clinical achievement more

often than a pathologic one." This observation, I feel, justifies the recording of the following case of coronary thrombosis, proven clinically and electrocardiographically, in a man with thromboangitis obliterans of the vessels of the extremities of nine years duration.

Case Report

C S, a native born, chauffeur and mechanic, of Russian-Jewish parents, forty-three years of age entered the hospital complaining of a dull pain across the anterior chest with marked general asthenia, this pain was aggravated by exertion and was associated with a choking sensation with marked dyspnea. No cyanosis was present.

The family and marital history was irrelevant.

He smoked on the average of seventy to eighty cigarettes a day for a period of at least ten years prior to 1927, when he reduced the number to twenty-five to thirty a day. For the past five years he has been smoking only eight to ten cigarettes daily.

The patient's health was good until the Winter of 1927, when, on exposure, his feet were frostbitten. The left foot recovered quickly, but the right foot and leg remained rather cold, of a bluish color and the nails of the toes were turning dark, particularly the nail of the little toe, which became almost black. This process did not go to gangrene. At the same time he noticed cramps in the right leg on walking, intermittent claudication after one-quarter of a block, compelling him to stop and rest.

He sought relief in the various city hospitals and clinics, where his condition was diagnosed as rheumatism, and given baking, massage, and internal medication without any relief.

Early in 1931, because of the intermittent claudication, marked pallor, and coldness of the plantar aspect of the right foot, as well as absent pulsations of the dorsalis pedis artery of the same foot, with the following oscillometric readings taken at that time:

Right post. tibial	237—234,	Osc. reading	0.3
Left " "	308—234,	" "	74

the diagnosis of thromboangitis obliterans or Buerger's disease was made.

Treatment directed towards this condition resulted in improvement so that he could walk at times a distance of eight blocks before the pain in the right leg began.

On September 7, 1936, while sitting quietly outside his home, he was seized suddenly with a severe, excruciating pain across the lower part of his chest and sternum.

Fig 1 Electrocardiogram, Leads I, II, III Heart Rate ninety per minute, "QRS" complexes low, diphasic, and slurred, "S-T" intervals slightly raised and coved, showing acute myocardial infarction

This pain, despite medical attention, continued unabated for thirty-six hours. He remained at home for one week and was then admitted to the hospital September 14.

The physical examination was irrelevant except for the right leg which showed no pulsations in the popliteal, tibial or dorsalis pedis. A sufficient collateral circulation must have been established because gangrene was not present although the color was abnormal. On elevation, the right foot became extremely pale and when lowered, it required more than three minutes for the return of color. At the base of the little toe and on the lateral margin was a round depressed scar, two cm. in diameter, the result of a healed ulcer. Laboratory examinations showed that the blood chemistry, blood count, and urine were normal. The blood Wassermann was negative.

Because of the history of severe, excruciating, and continued substernal pain, not relieved by treatment, the diagnosis of coronary thrombosis was made and later confirmed by the electrocardiogram. The pericardial friction rub and leukocytosis which are found frequently twenty-four to forty-eight hours following a coronary accident were not present upon his admission to the hospital, one week after the attack.

An electrocardiogram (Fig 1) taken the day after admission showed diphasic and slightly slurred "QRS" complexes in all the three leads with coved and slightly raised "S-T" intervals in leads 1 and 2—though these findings were suggestive of coronary

occlusion, they were not typical. Later electrocardiograms (Fig 2-3) taken on the tenth and twenty-third days after the coronary accident, clearly showed coving and deep inversion of the "T" waves in leads 1 and 2—the typical and classical picture of coronary artery thrombosis, "T-1" type. (These findings illustrate the importance of serial electrocardiographic examinations, so that many apparently negative cardiogram would show physical coronary changes if the examinations were repeated.)

With sedation and rest, the patient recovered from this coronary attack and was discharged from the hospital forty days after admission.

In thromboangitis obliterans the following process takes place

- 1 Infiltration of the coats of the vessels and surrounding tissues by inflammatory cells
- 2 Occlusive thrombosis of the affected segment of the vessel
- 3 Formation of purulent foci within the clot.
- 4 Replacement of the leukocytic areas by "altered angioblasts" and giant cells
- 5 Propagation of the clot without specific characteristics
- 6 Organization with extensive recanalization.
- 7 The appearance of lymphocytes and hemosiderin-filled large mononuclears
- 8 Finally, an acellular, organized, canalized thrombus with perivascular fibrosis matting together arteries, veins, and nerves

Comment

The occurrence of two diseases in a

single individual is always interesting, especially when the two conditions are of such comparative recent clinical and pathological recognition as coronary thrombosis and thromboangitis obliterans. The increasing frequency with which the literature has been reporting the coincidental occurrence of the two diseases in the same patient may be regarded as strongly suggestive of their common etiological origin.

As yet, only two cases have been definitely proven histologically as those of thromboangitis obliterans of the coronaries. However, when we consider the fact that coronary sclerosis may be but an advanced stage (end result) of thromboangitis obliterans, because the characteristics of both have been proven histologically to exist in a single lesion,¹⁴ and when, in addition, we realize that the heart does not lend itself to biopsy or amputation as the extremities do, so that the coronary arteries can only be studied at autopsy when the end result has taken place, one is justified in the assumption that there is more than a coincidental relationship between coronary thrombosis and thromboangitis obliterans.

As for the true etiological factors involved in the production of thromboangitis obliterans, we are as much in the

dark today as we were in 1924, when Buerger⁴ published his book. He advanced the theory "that an infectious agent is in all probability responsible for the 'acute' or earliest lesions." He justified this reasoning by the fact that in the early or acute stage of thromboangitis obliterans certain purulent foci make their appearance. However, up to this writing, no one has succeeded in isolating the offending organism.

Tobacco unquestionably plays a very important part as a predisposing factor and the case herein reported would seem to bear this out—for the patient consumed the astounding number of seventy to eighty cigarettes daily for a period of ten years prior to the onset of intermittent claudication. Perhaps this would also explain the fact that in all of Buerger's 500 cases, only three were women—but the use of tobacco has greatly increased among the female sex and to date there has not been a corresponding increase in the number of Buerger's disease among them.

Similarly, coronary thrombosis is three to five times as frequent in the male as in the female—this despite the fact that hypertension, which is sometimes thought to be a predisposing factor in its production, is far more frequent in the female.¹⁵

Fig 2 Electrocardiogram, ten days later, Leads I, II, III Heart Rate seventy-five per minute, "QRS" complexes diphasic, low, and slurred, "T" waves coved and deeply inverted in leads I and II, showing recent coronary artery thrombosis

Summary and Conclusions

1 Notwithstanding the extensive studies on coronary thrombosis and its relation to thromboangitis obliterans, it was not until 1936 that two cases were studied at autopsy and definitely proven histologically as cases of thromboangitis obliterans of the coronary arteries^{18 14}

2 There is a definite relationship between coronary thrombosis and thromboangitis obliterans

3 Buerger's conclusion that thromboangitis obliterans did not involve the

blood vessels of the viscera has been definitely disproven histologically

4 The probability is that at least one in every three individuals suffering from thromboangitis obliterans of the extremities has some coronary pathology, and one out of every two will die of a visceral vascular accident⁴

5 This report adds another case to the literature of coronary thrombosis, proven clinically and electrocardiographically, in a patient with thromboangitis obliterans of the right lower extremity

THE NEW PHARMACOPEIA

WARREN COLEMAN, M D, *New York City*

Ever since the publication of the deletions from USP XI this question has been insistently recurring to my mind

What are the functions of a pharmacopeia?

In seeking an answer I have reviewed USP I, the subsequent revisions and the dispensatories of London, Edinburgh, and Dublin. In the Preface to the first Pharmacopeia (1820) it is stated that "the object of a pharmacopeia (is) to select from among substances which possess medicinal power, those, the utility of which is most fully established and best understood and to form from them preparations and compositions, in which their powers may be exerted to the greatest advantage" (The "compositions," it may be explained, were approved combinations of drugs such as compound jalap powder, confection of senna, etc.) The earliest pharmacopeias contained primary and secondary lists of drugs, the first consisting of those whose actions were the better known

From this it is evident that the founders of the pharmacopeia considered its functions, among others, (1) to furnish a comprehensive list of drugs, and (2) to recommend combinations of drugs that had received general approval

The Convention of 1870 (USP V) adopted the following resolution, "that in the revision of the official list and formulas the wants of the medical profession in all parts of the US should be considered and that the scope of the work be extended rather than abridged" Yet in subsequent revisions an increasing trend toward abridgement may be observed. The Preface to USP XI states that the "The Eleventh Revision of the Pharmacopeia of the US is representative of approved therapeutic agents used in medical practice" The Pharmacopeia has therefore now become merely a restricted and selected list of the drugs used by physicians in this country. Only indirectly through its guaranties of the purity and strength of the drugs it lists and its directions to pharmacists and

manufacturers for making preparations from them is it of help to practicing physicians. There has thus arisen an entirely different conception of the functions of the Pharmacopeia from that entertained by the first and subsequent Conventions for some sixty or more years. For completeness it should be added that the same trend toward abridgement may be observed in the pharmacopeias of other countries

Such a radical departure from the original functions of the Pharmacopeia naturally leads to speculation on the reasons for the change

The Sub-committee on Scope of USP XI consisted of twenty-three members only a third of whom are actively engaged in the practice of medicine the others are pharmacologists and pharmacists. Deletions from and admissions to USP XI were based upon a majority vote in committee. And the question naturally arises whether the scope of the Pharmacopeia would have been different if clinical medicine had had greater representation on the Committee. I am convinced that physicians in active practice are the best judges of the therapeutic needs of the sick and of the usefulness of the drugs they employ. Certain it is that the general practitioner determines the fate of all drugs and therapeutic procedures irrespective of the auspices under which they are launched

Another reason for the new conception of the functions of the Pharmacopeia may be the disfavor into which the method of empiricism has fallen. But there is much to be said for the empirical method of observation in medicine. It has given the medical profession it has been estimated, forty per cent of the drugs in use to-day. Most of them have come down to us from the Greeks, the Romans, and Arabians. Among them are opium, vegetable purgatives, and chaulmoogra oil. Though of later date mercury and the iodides for syphilis, cinchona for malaria, ipecac for amebic dysentery, and digitalis are the products of empiricism. The therapeutic

victories of empiricism, I venture to say, outnumber those of pharmacology, physiology, and bacteriology combined. Although empiricism at times may lack controls and its followers differ in the ability to observe and record facts, the multitude of experiments usually corrects these deficiencies. Moreover empiricism possesses a control that cannot be imported into a laboratory, namely, the psyche. The psyche may mislead but it is an invaluable control. No laboratory animal can tell the observer how it feels.

Without in the least intending to belittle the scientific approach to medical and therapeutic problems, I would emphasize my belief that the practice of medicine is an art. Moreover, it is an art that may be acquired only by long training at the bedside, and until the X quantity in the biological reactions of the human body especially in disease to its environment is found, the practice of medicine will continue to be an art.

Medicine is under a great debt to the sciences, especially to physiology, bacteriology, biochemistry, and pharmacology. But the ability to observe and record facts accurately is a quality of mind and is largely independent of time or place or equipment. For instance, with all the study that has been devoted recently to digitalis no essential action has been added to those described by Withering one hundred and fifty years ago. Perhaps the greatest contribution of pharmacology has been to furnish explanations of well-known actions of long-known drugs. It has been asserted that one of the functions of pharmacology is to destroy the faith of clinicians in certain of their drugs. But pharmacology has its limitations as well as clinical medicine. Such an attitude is not without its dangers. Even the latest scientific tests of a period may not suffice to refute clinically established facts. For more than a century cod-liver oil had been found by physicians to possess special therapeutic virtues. Yet some twenty-five years ago pharmacologists chided physicians for still believing that cod-liver oil possessed any actions not shared by other animal oils. And not long thereafter vitamins were discovered.¹ Cod-liver oil was found to contain vitamins A and D but there is reason to believe that science has not yet

solved the therapeutic riddle of this old fashioned remedy.¹

Deletions

To comment briefly on some of the deletions from USP XI and other recent revisions

Calumba and quassia are just as bitter as they ever were and just as good stomachics. Why should they not be retained? The human palate has many vagaries and is slow to forgive insults.

Colocynth, jalap, rhubarb and soda mixture, and compound cathartic pill, all have been cast out of the Pharmacopeia. And the practicing physician is left to wonder how many of those voting for the deletion of these drugs and combinations have had under their ministrations constipated, colon-conscious, neurotic women? The alternative to changing their medicines is often self-sought and directed colon irrigations with quarts and quarts of water "until the mucus is brought away."

The infusion of digitalis was a favorite prescription of master clinicians of a generation ago. Now that digitalis is standardized, the infusion should be more useful than ever. From my more recent experience, I am convinced that a weaker preparation than the tincture of digitalis is needed. There would be fewer instances of over-digitalization if one were official and used. In my opinion the medical profession and drug manufacturers have too greatly stressed the relation of cat-unit to digitalis dosage. In none of their writings did Hatcher and Eggleston even suggest that the optimum dose of digitalis could be found by means of the cat-unit and the multiplication table. The only method by which it may be found is with the aid of the clinician's finger and ear.

Changing of Names

Another criticism I would make of the Pharmacopeia is the constant changing of names. Even intelligent laymen knew that spiritus vini gallici is brandy, now it is spiritus vini vitis, as though gallic wine were not a wine of the grape. Pulvis digitalis foliorum has been changed to digitalis pulverata, the one indicating the process of reduction, the other the phys-

ical state of the powder Compound licorice mixture is now *mistura opii et glycyrrhizae composita*—if the young practitioner does not know that brown mixture contains paregoric, the fault lies in his instruction in *materia medica*.

It has become the fashion now-a-days to group combinations of drugs as "shot-gun" mixtures, thus ignoring the doctrines of synergism and correctives. And formulas have largely disappeared from the Pharmacopeia. The British Commission takes the stand "that the prescribing of combinations of drugs should be left to the individual practitioner"². But the young practitioner at least in America has not been taught sufficient *materia medica* to make up satisfactory combinations. Moreover, not every practitioner is capable of creating a Dover's powder, a Stokes' expectorant or a Fothergill pill. Standardized formulas, compounded on the experiences of many clinicians with the technical assistance of pharmacists, are far superior to any combinations the physician may extemporize in his office or at the bedside. The alternative to including a reasonable number of formulas in the Pharmacopeia in my opinion is increase in the use of patent and proprietary medicines with the consequent evils of such practice.

The Pharmacopeia and Instruction in *Materia Medica* and Therapeutics

From its beginnings the Pharmacopeia has been the standard for instruction in *materia medica* and therapeutics. Drugs not in the Pharmacopeia or that have been deleted from it are often considered to have been proved worthless. They are not included in textbooks and students are taught little or nothing about them. Yet when recent graduates enter upon their internships they find some of these drugs in their hospital formularies and that others are favorite remedies of their visiting physicians. Textbooks on *materia medica* and therapeutics have been replaced by textbooks of pharmacology in which the sections on therapeutics have been written by men who rarely or never see a patient. The Chairs of Therapeutics have been abolished in some of the best medical schools. Recently it has been stated in print that there is not time in

the medical curriculum to teach prescription-writing.³

In such circumstances it is scarcely surprising the belief is widespread that the instruction of medical students in *materia medica* and therapeutics is deficient. After analyzing the replies to a questionnaire addressed to the secretaries of all State Boards of Medical Examiners on the relative standing of the candidates in *materia medica* and therapeutics, David⁴ concludes that the survey presents definite evidence that recent graduates know little about the use of drugs when they begin the practice of medicine. Unfortunately hospital interns are not required to learn the components of the mixtures they employ, or the reasons for combining them, and too often they fall into the habit of prescribing them by name or number. Pharmacists complain and prescription surveys indicate that a large percentage of the prescriptions given to patients by physicians call for ready-made patent and proprietary preparations. There must be a reason for this. And I am disposed to think that at least a share of responsibility falls upon the policies followed in the last several revisions of the Pharmacopeia. Some of the drugs that have been deleted are in constant use by many physicians. Some of them have been in use for 2000 years and more—before pharmacopeias were thought of—and will still, or again, be used when pharmacopeias are no longer printed.

National Formulary and Pharmacopeia

Among the reasons that called the National Formulary into existence was the "well-known (fact) that the remedies for which the Pharmacopeia prescribes definite standards constitute *only a limited portion of the resources* of the medical profession in the treatment of the sick"⁵. The National Formulary undertook to establish standards for these unofficial "resources" and these standards have since been given the force of the law. The difference between the Pharmacopeia and the National Formulary is thus summarized in NF V (1926) "The Pharmacopeia is a standard of therapeutic agents, the National Formulary is a standard for pharmaceutical formulas

victories of empiricism, I venture to say, outnumber those of pharmacology, physiology, and bacteriology combined. Although empiricism at times may lack controls and its followers differ in the ability to observe and record facts, the multitude of experiments usually corrects these deficiencies. Moreover empiricism possesses a control that cannot be imported into a laboratory, namely, the psyche. The psyche may mislead but it is an invaluable control. No laboratory animal can tell the observer how it feels.

Without in the least intending to belittle the scientific approach to medical and therapeutic problems, I would emphasize my belief that the practice of medicine is an art. Moreover, it is an art that may be acquired only by long training at the bedside, and until the X quantity in the biological reactions of the human body especially in disease to its environment is found, the practice of medicine will continue to be an art.

Medicine is under a great debt to the sciences, especially to physiology, bacteriology, biochemistry, and pharmacology. But the ability to observe and record facts accurately is a quality of mind and is largely independent of time or place or equipment. RADIOLOGY AND THE RADIOLOGIST OF THE FUTURE

FREDERIC E. ELLIOTT, M.D., *Brooklyn*

The announcement of Professor Wilhelm Conrad Roentgen of his discovery of the x-rays, some two score years ago, opened the way for romantic adventure of human intelligence into unexplored fields. An account of the various steps of progress through which mechanical and chemical devices with creative understanding have advanced the use of the x-rays to the benefit of mankind would be both interesting and a source of inspiration. However, time and our present purpose do not permit of such review of this epoch, filled as it has been with the work of the pioneers, the pathfinders and the martyrs with their individual and group contributions to what is now called Radiology. We dismiss this consideration of our subject with humble and generous acknowledgments to all of those men and women whose accomplishments have made possible so much precision and certainty in the practice of the healing art.

Reluctantly, we turn our discussion from the glories of the past to face the realities of the present. We serve a public whose mind is materialistic, practical. That public is interested in our Radiology for the service which it may render at the time of injury or sickness. And we, who engage in the practice of Radiology, may well consider our work from this social economic viewpoint. It is timely that we ask ourselves and our colleagues, these questions:

Is the present use of x-rays in medicine attaining the greatest possible good?

In what ways can the professional and social worth of this science be made more effective and helpful?

What, if any, are the influences which stand in the way of further desirable progress in such directions?

These must be intelligently answered if the Radiologist of the future is to be something more than a memory of an extinct branch of the medical profession. It is my opinion that Radiology of

today is not rendering its full possible benefits that the scope of its use can be broadened and the quality of service improved. Well-entrenched and powerful influences must be overcome if such ends are to be attained and the wrongs of present-day conditions are to be corrected. We must face the hard, cold facts. Customs and habits of thought must be reshaped to proper understanding. Commercial greed must be curbed. Our public must be made to understand our problems as we see them. When this is done an enlightened public will ally the weight of its opinion with our efforts. The public and the Radiologists have mutual interests in the promotion of proper use of the x-rays in Medicine.

One thought may seem academic and trivial, yet to my way of seeing, it is the most important. The demonstration of the human body parts by means of x-ray shadow images is, in fact, a physical examination. Yet, commonly our public and our colleagues refer to these images as pictures—to the end that Radiology is too commonly regarded as mere photography. Radiologists are themselves largely responsible for this state of affairs. To a technical audience it is not necessary to discuss the distinctions between objective surface images produced by the reflected parallel rays of ordinary daylight illumination and the superimposed shadows of interior parts, accomplished by divergent Roentgen rays and registered upon a film or fluoroscopic screen. The lay mind does not grasp the understanding that anatomical parts and functions are presented quite differently in the x-ray image as compared with the objective optical image. Even our professional brothers often fail to appreciate the necessity of the practical knowledge of x-ray-anatomy, x-ray-physiology, and x-ray-pathology before an interpretation of the x-ray image can have real value.

We, who practice Radiology, are largely

in use by physicians." In other words, the Pharmacopeia is the expression of the opinions of the Sub-committee on Scope concerning the therapeutic usefulness of drugs inferentially, drugs that have not been admitted, or that have been deleted, are considered less useful or useless. The National Formulary reflects the current use of drugs and formulas by the medical profession. The Committee that compiles it disclaims all therapeutic responsibility. The drugs and formulas deleted from the Pharmacopeia are usually admitted to the National Formulary. But to be admitted, a drug must have been called for in twenty per cent of the drug stores of the United States or once in each 10,000 prescriptions. If the purpose of the Committees of Revision of the more recent Pharmacopeias in restricting the titles has been "educational," it would seem to have failed. Prescription surveys prove that physicians will not confine their prescribing to the drugs selected for them, instead they are turning to ready-made patent and proprietary preparations. Such a situation should command the attention of the Pharmacopeial Convention, of educators and perhaps of the American Pharmaceutical Association, and remedies sought to correct it. The responsibility for the situation lies primarily, I believe, at the doors of the Pharmacopeial Convention and the medical colleges.

Remedies

1 To bring the Pharmacopeia more nearly into accord with the opinions and therapeutic practices of general practitioners. It would be better policy, I believe, to include in the Pharmacopeia drugs whose actions have not been, or cannot be, proved on laboratory animals than indirectly to encourage the use of patent and proprietary remedies. Similarly, a reasonable number of long-approved formulas should be included in the Pharmacopeia.

2 To give students much more thorough instruction in materia medica, therapeutics, and prescription writing even at the expense, if necessary, of parts of the courses in preclinical sciences. The great objective of medical education after all is the training of practitioners of medicine.

Greater familiarity with the drugs in common use and with formulas created by master clinicians would, I believe, protect both physicians and the public against exploiters of drugs.

WIDER HIGHWAYS HAVE MOST WRECKS

According to the *Associated Press*, making the automobile highways wider evidently has increased the risk of accidents and would seem to be the cause of a higher proportion.

On Jan 21 this statement of facts was reported to the American Society of Civil Engineers by Arnold H Vey, who is Traffic Engineer of the State of New Jersey. Mr Vey states that in New Jersey 2-line highways have an accident rate of 275 for every million miles of automobile travel, the rate for the 3-line roads is 353, and the rate for the 4-line highways is 361.

According to Mr Vey, the increased proportion of accidents on the wide roads is due principally to the more flexible movement of traffic from side to side. The wide

highway cuts down some accidents and increases others. Right-angle collisions, head-on smashes, and running into fixed objects were recorded less often on wide roads.

Collisions by automobiles running in the same direction were more frequent. Peculiarly as it may seem, accidents to pedestrians were reduced very little by widening the roads.

It is claimed that much of the danger from wide roads can be eliminated by proper control. Pedestrians should have sidewalks or paths. Mr Vey states, "It is significant that 21 per cent of New Jersey's automobile accidents occur on highways which total only 6 per cent of the state's roads."

undertakes his training for the practice of Radiology with a first seasoning of his medical knowledge by five to ten years in the general practice of medicine starts with a handicap which only unusual talents and effort can overcome. Only after surmounting great difficulties will he ever rise above the level of a mere photographer. Consideration of the public interest will eventually require such probational experience in general medical practice from all who desire to engage in the practice of Radiology. One of the absurdities of the present era is the medical novice who sprouts the plumage of a specialist before his quill feathers are full-grown. The hazards to human health and life will justify throwing strict restrictions around the practice of all the medical specialties, especially those in the diagnostic group.

When Radiologists have been recognized as consulting diagnosticians, making a special form of examination, it will be easier, perhaps, to educate our colleagues not to undertake to dictate the method of procedure. We would like to bear at length on this, but two points are particularly in mind. Physicians who make a careful clinical study of their patients seldom subject them to the expense of needless x-ray examination. When an x-ray examination is ordered upon a mere presenting symptom or other superficial consideration, or as a "first-step" approach to an understanding of an injury or illness, it frequently results in a finding of negative value to the patient and brings displeasure if not discredit to those who have participated. The physician who habitually calls for stereoscopic films subjects his patient to added expense. This will be of less frequent occurrence when it is more generally appreciated that such films, made as they must be with a beam of divergent rays at relative close range, are not truly stereoscopic and so often falsely represent the depth relationships. We are convinced that the trained and experienced Radiologist subconsciously corrects the inescapable distortions produced by the beam of divergent rays, and instead of reading the flat picture-like image on the film, he reconstructs between himself and the film a phantom image of the parts, arranged in their true relationships, and from such phantom

image he reads a truer interpretation than can be gotten from the imperfect optical illusions of a stereoscope.¹

We sometimes wonder if our friends, who undertake to direct the technic method of our examinations, ever realize the unwarranted presumption of such an act. They understand little of the physics of shadow projection and less of the standardized procedures of present-day Radiologic practice. How much greater service they would render their patients if they would only reduce the patient's need to a statement of a clinical problem, leaving the selection of procedure to the one who is expert in Radiologic practice.¹

More might be said and other points could be cited with profit, however, so much for the wrongs that have been established by custom and habit-conduct. In the immediate present, the public suffers greater economic injustice and more questionable professional service in consequence of commercial greed. The Federal government, in an effort to relieve financial distress of unemployment, opened the flood gates of money and easy credit as a means of starting the wheels of industry. Certain of the manufacturers of x-ray equipment have exploited the opportunity of easy money created by the Federal Housing Act. High pressure salesmanship has been applied to every physician who would give the time to listen. It has been represented that with no original investment, the physician might collect the fees of a specialist in Radiology and relieve his own economic distress, and at the same time easily discharge the financial obligation for the equipment out of such "easy money." Pertinently these salesmen have urged "that the doctor around the corner or up the street has ordered a machine and your patients will be leaving you for the other doctor who has an x-ray machine in his office." Literally, thousands of fluoroscopes and bedside units have been installed and the overcredulous doctors have undertaken to reap the harvest. After the signature has been placed on the dotted line, the manufacturer collects his money in full, and goes on his way to enjoy a hitherto unknown prosperity. But the poor doctor is left to a sorrowful realization that the purchase of an x-ray generating apparatus is the smallest item

responsible for wrongs which have arisen out of this "picture" ideology. We have held our films before interested eyes and asked them to see certain things. Because of our enthusiasm and pride in our craftsmanship we have disregarded the fact that back of such eyes there was not the same conscious and subconscious faculties which, time and experience with careful regard for factors of physics and chemistry, have developed in the mind of the trained Radiologist. We have not been content to render our opinions; we have sought to demonstrate the truth of them—by evidence which the observer was unprepared to properly evaluate. We have built up the appreciation for a "picture" and undermined the value of expert "opinion." We have called it a picture, it looks like a picture, and so "why not?" Thus, doctors and patients are now demanding the technical evidence of our examinations, that they may re-evaluate a conclusion upon which an expert opinion has been rendered. Nothing has so much injured the status of Radiology as has this common practice of "picture" exhibition.

We would like to extend this topic to considerable length but time limits us to two pertinent citations. Just now we hear much about Silicosis. We hear about "pictures of silicosis." Of course, every intelligent physician knows the gradation of changes which occur between the first slight loading of the respiratory tissues with silica, or kindred dust substance, and those manifestations which come with progressive accumulations. Likewise, every clinician knows that concomitant disease of other nature may be and commonly is coincident with "dust" accumulations in the lung tissues. The evaluation of the meaning of the density changes becomes an examination problem and not a photographic demonstration or exhibition. Now, take another field, the bone fracture; any one can detect the fault in the continuity of bone outline. It seems like a simple performance to make such an interpretation. I once had a lawyer assert that he was an expert on reading fracture case films and he supported his point assuredly on the fact that he possessed in his files more than 150 films of court cases. He felt confident that this range of experience had properly quali-

fied him in this field. He was blissfully indifferent to the necessity of appraising the relationships of the parts, or the recognition of concurrent pathologic change. Thousands of physicians with scarcely greater radiologic experience and no training falsely assure themselves of competence which is, in fact, little above that of our legal friend.

We know of an instance in which a railroad brakeman, working on a freight car, suffered a fracture of both ankles. He was given care in a hospital where x-ray films are made by a photographer and the surgeons make their own "reading" of the films. The fractures would not unite. After failure of osteoplastic operations on one side, the foot was amputated. It was then proposed to amputate the other foot. At this point the man's case came up in court and the railroad paid \$20,000. The day before trial a consultant Radiologist recognized luetic changes in both tibias. He was not called into court to give testimony, but had the satisfaction of knowing that the other fractured ankle united promptly under proper antiluetic therapy. From our limited range of experience we could cite many other instances of harm which have resulted from incompetent interpretation of the x-ray evidence.

The x-ray image is not a picture, albeit the image is registered in a photographic emulsion by photochemical processing. But "pictures" they will be in the minds of the public and our medical profession until such time as we, ourselves, discontinue such misnomer. It has been said that digestion of food begins in the kitchen. Truly the interpretation of an x-ray image begins with the technic of its production. When Radiologists stop the use of the word "picture" they may rise above the status of radiographers or photographers.

A correlate to the idea that the Radiologist examines rather than photographs a patient is the belief that the Radiologist must qualify as a diagnostic consultant. There will be greater value to the patient when the Radiologist correlates the clinical data with the x-ray image interpretation, than when the clinician reads his clinical conclusions into the fancied details of the radiographic evidence, as he sees it. A physician who

undertakes his training for the practice of Radiology without a first seasoning of his medical knowledge by five to ten years in the general practice of medicine starts with a handicap which only unusual talents and effort can overcome. Only after surmounting great difficulties will he ever rise above the level of a mere photographer. Consideration of the public interest will eventually require such probational experience in general medical practice from all who desire to engage in the practice of Radiology. One of the absurdities of the present era is the medical novice who sprouts the plumage of a specialist before his quill feathers are full-grown. The hazards to human health and life will justify throwing strict restrictions around the practice of all the medical specialties, especially those in the diagnostic group.

When Radiologists have been recognized as consulting diagnosticians, making a special form of examination, it will be easier, perhaps, to educate our colleagues not to undertake to dictate the method of procedure. We would like to bear at length on this, but two points are particularly in mind. Physicians who make a careful clinical study of their patients seldom subject them to the expense of needless x-ray examination. When an x-ray examination is ordered upon a mere presenting symptom or other superficial consideration, or as a "first-step" approach to an understanding of an injury or illness, it frequently results in a finding of negative value to the patient and brings displeasure if not discredit to those who have participated. The physician who habitually calls for stereoscopic films subjects his patient to added expense. This will be of less frequent occurrence when it is more generally appreciated that such films, made as they must be with a beam of divergent rays at relative close range, are not truly stereoscopic and so often falsely represent the depth relationships. We are convinced that the trained and experienced Radiologist subconsciously corrects the inescapable distortions produced by the beam of divergent rays, and instead of reading the flat picture-like image on the film, he reconstructs between himself and the film a phantom image of the parts, arranged in their true relationships, and from such phantom

image he reads a truer interpretation than can be gotten from the imperfect optical illusions of a stereoscope.¹

We sometimes wonder if our friends, who undertake to direct the technic method of our examinations, ever realize the unwarranted presumption of such an act. They understand little of the physics of shadow projection and less of the standardized procedures of present-day Radiologic practice. How much greater service they would render their patients if they would only reduce the patient's need to a statement of a clinical problem, leaving the selection of procedure to the one who is expert in Radiologic practice!

More might be said and other points could be cited with profit, however, so much for the wrongs that have been established by custom and habit-conduct. In the immediate present, the public suffers greater economic injustice and more questionable professional service in consequence of commercial greed. The Federal government, in an effort to relieve financial distress of unemployment, opened the flood gates of money and easy credit as a means of starting the wheels of industry. Certain of the manufacturers of x-ray equipment have exploited the opportunity of easy money created by the Federal Housing Act. High pressure salesmanship has been applied to every physician who would give the time to listen. It has been represented that with no original investment, the physician might collect the fees of a specialist in Radiology and relieve his own economic distress, and at the same time easily discharge the financial obligation for the equipment out of such "easy money." Pertinently these salesmen have urged "that the doctor around the corner or up the street has ordered a machine and your patients will be leaving you for the other doctor who has an x-ray machine in his office." Literally, thousands of fluoroscopes and bedside units have been installed and the overcredulous doctors have undertaken to reap the harvest. After the signature has been placed on the dotted line, the manufacturer collects his money in full, and goes on his way to enjoy a hitherto unknown prosperity. But the poor doctor is left to a sorrowful realization that the purchase of an x-ray generating apparatus is the smallest item

in the equipment of a Radiologist. We have confidence in the honesty of our profession and firmly believe that within a few months most of these instruments will become mere ornamental decorations. But there are some men licensed to practice medicine (and we regret the truth of this statement) who are not scrupulous. These men are not competent and will never become proficient in Radiology. They will fluoroscope their patients and make films, and an unsuspecting public will pay fees for a supposed service, for a service which, in fact, has no true value. Thus, a credulous public has been subjected to a mongrel exploitation to satisfy the greed of commercial enterprise. Gullible physicians have been tempted into betrayal of public confidence and are left holding the bag. The unscrupulous have been encouraged and financially aided in their mercenary misconduct. We further regret to say that some respected members of our profession, suffused with egotistical self-esteem and self-appreciation, will less quickly lay aside activity in this field of practice. We have seen some, highly regarded and truly expert in their respective special fields, verge upon apoplectic convulsions while denouncing other physicians who venture into their particular range of practice without proper training and experience, yet they themselves, with a nonchalance that would be amusing if it were not tragic, boldly exhibit their amateur abilities in the field of Radiology with utter disregard of the inconsistency of their acts.

"O wad some Power the giftie gie us
To see ourselves as ithers see us!"

The public will soon have one means of self-protection. The American Board of Radiology is an authoritative body. After due investigation and examination, this Board will certify and grant diplomas to those who are properly qualified to practice Radiology. An intelligent public will then heed the expert interpretation of x-ray examinations and will refuse to be mulcted for "specialists' fees" by the untrained and inexperienced. Until such time as this Board has had opportunity to complete its task, the careful citizen will do well to regard with suspicion any small and incomplete equipments which are operated by physicians who are with-

out established recognition as Radiologists in their home communities. We must honor the general practitioner in the rural community who adds a small radiological unit to his needs for emergent cases—he never indulges in the despicable abuse of public confidence by seeing "a spot" on the lung with a fluoroscope, repeated as frequently and as far as the victim remains unsuspecting and credulous, at \$10.00 per look.

Commercial greed has projected its ugly head into this field of medical practice. Institutions owned by laymen, some operated under hired licensed physicians, advertise, solicit, and rebate in order to acquire patronage. While the public attention has been focused upon surgery, it must be emphasized that the public is mulct of a greater sum of money thru the needless x-ray photographs made by commercial institutions upon which a fee split is kicked back to the referring doctor. It is a sad commentary on present medical ethics that so many physicians profane their profession by the acceptance of such betrayal of confidence. The morals of the profession have been impaired. During the past session of the New York State Legislature a bill was introduced to more clearly define the Education Law as it relates to the practice of Radiology. The bill was defeated by holding it "in committee," and the chairman of the committee of the Senate alleged that he was taking such action upon the appeal of two commercial laboratories located in Manhattan, who feared its consequence upon their outlaw activity in the commercial vending of medical service.

Another threat against Radiology is the activity of recognized hospital institutions who utilize Radiology as a "source of revenue." Effort has been made to draw a distinction between the technical production of the x-ray film-image and the professional practice of interpretation. If this move were successful, the hospital could possibly justify itself, and the practice of Radiology would largely resolve itself into the incompetent interpretation of untrained members of the staff of each hospital who would be encouraged to determine the "reading" of their own case "pictures." We are honestly convinced that no hospital should be permitted to

receive a revenue from the practice of Radiology, or from any other branch of medical practice, nor should any institution be permitted to practice a competitive activity which would be prejudicial to the welfare of the Radiologic profession and, therefore, against the welfare of the public. This principle is sound and vital to the future of Radiology. The place of the Radiologist in relation to Hospital Administration as an employee is weighted with degrading implications. Radiologists and allied specialists in Pathology, Anesthesia, and Physical Therapy must be integrated with the Medical Board to give recognition in keeping with professional attainment and in conformity with the respect accorded other medical colleagues.

Unless the wrongs in the present use of x-rays in medicine are corrected, the reaction of public opinion will prejudice present esteem for the medical profession when the truth is realized.

We have said that the service of Radiology to the public could and should be broadened. Take for example one field—tuberculosis. It is important that "case finding" be extended as far as possible. One commercial concern has perfected a rapid-fire technic by which great numbers can be paraded before the x-ray tube, at a low cost. The fault with this program has been that the materials utilized have been of such character that the slightest changes of density and vascularity, which signal the initial pathologic change, are not detected. Thus a patient in the most amenable stage of his infection may be sent on his way with the false sense of security that he has no tubercular infection. The transparent film image is better suited for the examination of such cases. The Radiological Guild of New York is now working out a program which will make "screening examinations" possible on a practical, economic basis. Announcement of this program will be made in *Roentgen Economics* and other publications during the Summer.

The Radiologist of the Future

One may well ask if there will be such a creature in another generation. Good medical care will be available for the

American people only if the economic foundations of medical practice are maintained. Likewise, Radiology will remain a virile specialty in medical practice or it will become extinct, according to its economic supports. If commercial interests are permitted to continue exploitation of this professional field, if hospitals and clinics may continue to operate in this field for revenue or practice unfair competition, if the profession at large is to continue to undertake this form of physical examination without proper training and experience—in other words, if the vastly greater part of the practice of Radiology is to be taken from those physicians who have been trained and experienced, then the discouragement and demoralization of poverty will disband and destroy and with time extinguish the Radiologist from the future. The specialty of Radiology cannot be sustained on the economic foundations which arise from the examination of the unusual and difficult case—many of which arrive at the hands of the expert Radiologist only after amateur efforts have dissipated the individuals' financial resources.

We have confidence in the honesty of the medical profession individually and collectively. The exceptions only serve to make the faith more vibrant. We believe that the profession will return radiologic examinations to the competent Radiologists. If this does not occur the ultimate reaction of public opinion will be severely harmful to the entire profession of medicine. We believe that Radiologists must become vocal within the halls of professional conferences. We must make the wrongs of present conditions evident and odious. On the constructive side, we must plan and universally support programs which will extend the usefulness and availability of Radiology to the full possible reach of its possibilities of service to the public and our professional colleagues.

The Radiology of the Future will be what we Radiologists of today make of it. We owe to the people of our nation the protection of our heritage.

PRESENT STATUS OF LARYNGEAL TUBERCULOSIS

A Review of 245 Cases

DAVID I. FRANK, M D and GEORGE D. WOLF, M D, *New York City*

Associate Laryngologist, Riverside Hospital, and Instructor of Oto-Laryngology, Post-Graduate Hospital, Oto-Laryngologist, Sydenham Hospital, and Laryngologist, Riverside Hospital

The pessimistic attitude with regard to the prognosis of tuberculosis of the larynx held two or three decades ago is not tenable today. Where, at the beginning of the century, the advent of laryngeal tuberculosis was considered as rendering the prognosis invariably hopeless, today the outlook is much brighter. To a large measure such a more favorable outlook is directly attributable to the advances in the diagnosis and treatment of the pulmonary disease, rather than to any startling improvements in the treatment of the laryngeal complication. The incidence of local involvement in the larynx has also diminished. Fifteen or more years ago it was an everyday expectancy to see one or more cases of tuberculosis of the larynx in the outpatient departments of our hospitals, but today such cases are rarely seen in the throat clinics of even our most active institutions.

A review of 245 cases of laryngeal tuberculosis is herewith presented with the intention of recording our observations with respect to etiology, diagnostic and pathological features, and therapeutic measures, and correlating our findings with those presented by the many laryngologists who have had much experience with this disease.

This survey covers a period of three years and has been obtained from our patients at the Riverside Hospital in New York City, an institution for tuberculous patients.

Etiology

Incidence of Laryngeal Involvement in Pulmonary Tuberculosis

During a three year period we examined 1719 cases of pulmonary tuberculosis and found that 245 (14.2%) had the laryngeal involvement. There is a wide variation in the statistical reports as to the incidence of laryngeal tuberculosis.

Lederer and Fishman¹ report fifteen per cent, Kemler² sixteen-twenty per cent, Van Poole³ 22.9 per cent, St. Clair Thompson⁴ 18.7 per cent, Looper and Schneider⁵ 15.5 per cent, and Dworetzsky⁶ 25.6 per cent. Vandeverer⁷ reports as low a percentage as 3.24, and Hayes⁸ reports as high a percentage as forty-fifty per cent. This considerable variation may be entirely accounted for by the different criteria on which a definite diagnosis of laryngeal tuberculosis is made. Only the early cases of this complication can account for the disagreement. Certainly there should hardly ever be a question concerning the diagnosis of the moderately advanced or advanced cases. There is a similar discrepancy in the reports of postmortem findings. Cooper and Benson⁹ report 28.3 per cent laryngeal involvement in 798 cases examined on autopsy. Fetterolf,¹⁰ in a study of one hundred postmortem examinations, found the larynx involved in eighty-seven per cent. F. R. G. Heaf¹¹ reports sixty-eight cases of tuberculosis of larynx out of 150 necropsies—a percentage of 45.3. This wide variation in postmortem findings is rather difficult to understand.

Age

The following figures show the frequency of laryngeal involvement in the various age groups in our series.

10-20 years	6%
20-30 "	33%
30-40 "	21%
40-50 "	20%
50-60 "	16%
60-70 "	4%

These figures are in accord with almost all other reports on age preference for laryngeal complications. St. Clair Thompson,⁴ Coakley,¹² and Dworetzsky⁶ found the larynx involved most frequently between the ages of twenty and forty.

From the Laryngological Service of Riverside Hospital

Laryngeal tuberculosis is extremely rare in children. The disease is seen infrequently in patients over forty-five. In our series, the oldest patient was seventy years of age.

Sex

There is some discrepancy in the reports as to the predominance of the disease in males or females. St. Clair Thompson reports that it occurs as frequently in males as in females, Spencer¹² finds it to be more frequent in males, in the proportion of three to two, Van Poole,³ five males to four females. We have found a six to five proportion in favor of males.

Mode of Invasion

It seems to be conceded that primary tuberculosis of the larynx does not exist. The most plausible theory of invasion is through the laryngeal mucosa from the secretions of the lungs, laden with tubercle bacilli—the so-called sputogenic theory. The more frequent occurrence of the laryngeal pathology in the posterior part of the larynx where the sputum is more prone to collect and remain in contact with the larynx for many hours, especially during sleep, seems to substantiate this theory. Aside from this mechanical interpretation, the type of epithelium is also a factor in rendering this part of the larynx more vulnerable. The arytenoids, interarytenoid region, and the edges of the vocal cords are covered by papillated mucous membrane, and are more vulnerable than parts of the larynx covered by ciliated columnar epithelium.

Although the sputogenic route is held to be the predominant mode of invasion, there are many who feel that hematogenous and lymphogenous invasions are responsible for many cases of laryngeal tuberculosis. Certainly, in cases where tubercle bacilli are absent from the sputum, one cannot possibly attribute invasion to this source. In our series we have found twenty-two cases with negative sputum, and it is worthy to note in this regard that thirteen were mild cases, five were moderate, and four severe.

Wood¹⁴ describes four possible ways by which the tubercle bacilli may gain access to the subepithelial tissues from the surface:

- 1 Through the unbroken epithelium
- 2 Through ducts of the racemose glands
- 3 Through traumatic abrasions
- 4 Through pathological epithelium

Torin,¹⁵ in reviewing the mode of invasion, asks the following questions: "Why is tuberculosis of the trachea and bronchi, where the sputum accumulates and lingers for even longer periods of time than in the larynx, rare? How can one explain laryngeal involvement in cases in which the pulmonary lesion is circumscribed and has no direct communication with bronchi and trachea? Why does the larynx escape involvement in cases of long-standing pulmonary phthisis in which the larynx is constantly bathed in bacilli laden sputum?" Thus, because of the absence of definite evidence of invasion, we must accept all three routes as likely, but the sputogenic theory seems the more probable.

Diagnosis and Pathology

Stress must be laid here on the fact that tuberculous laryngitis is not pathognomonic. In typical cases, diagnosis is simple, in atypical ones, it is frequently impossible.

A routine examination is made on every patient admitted to the hospital. The ambulatory patients are examined in our laryngological clinic, and the bedridden in the ward. Indirect laryngoscopy is the method of examination. In only a very few cases has there been need for the direct examination. We feel that the direct method is too great a strain on a tuberculous patient and should be resorted to only on rare occasions.

In spite of the laryngologist's deft and skillful use of the laryngoscope we believe that this examination entails both mental and physical strain. There is also a great possibility of trauma which may spread the laryngeal disease. Schught¹⁶ informs us that early lesions in the ventricle are invariably missed by mirror laryngoscopy and that lesions elsewhere in the larynx are relatively dwarfed, and on that account he insists

on the direct method Of course, it cannot be denied that a more accurate examination of the larynx is assured by such procedure, but we feel that for all purposes concerned, the mirror will demonstrate sufficient pertinent findings on which to base a diagnosis The regions of the larynx most difficult to view with the mirror are the anterior commissure and ventricles, and it is admitted by those specialists experienced in the field of laryngeal tuberculosis that the incidence of involvement in these localities is rather infrequent.

The symptoms are very indefinite in the early cases and are of no assistance in diagnosis Hoarseness, though usually a late manifestation, is sometimes the first symptom for which the patient presents himself Hence the necessity for alertness on the part of the examining physician Hoarseness depends on the involvement of the cords or cricoarytenoid joints Dysphagia and odynphagia are usually late symptoms present with ulceration, chondritis, and necrosis of epiglottis Occasionally these latter symptoms are also manifest with involvement of arytenoids or aryepiglottic folds The contact of food and saliva with these areas results in the excruciating pain of which these patients complain Dyspnea occurs when there is glottic closure which may be due either to intense edema or marked productive lesions Dyspnea may also occur with extensive lung involvement

Early symptoms often appreciated by patients before hoarseness are a tickling, burning or lumpy sensation in the throat, and early vocal fatigue on talking However, these symptoms cannot be relied upon because of their uncertainty and inconsistency

Contrary to the general belief that hoarseness is an ever present symptom, we found it only in 115 of our series This figure does not coincide with the number of our cases recorded who had vocal cord involvement (153) This may be explained by the absence of sufficient pathology in the vocal cords to interfere with phonation to the degree of being appreciated by either patients or physician Schught,¹⁶ recording his experiences with over 500 cases, reports that "Hoarseness, although an early

symptom of carcinoma, often develops in tuberculosis after the larynx is already widely involved Even involvement of one or both cords may cause no noticeable change of voice" The great incidence of cord involvement confined to the posterior parts, may further account for freedom from hoarseness

The region of the larynx more prone to attack is demonstrated in the following (our series)

Vocal cords	153
Arytenoids	122
Interarytenoid sulcus	83
Epiglottis	53
Ventricular bands	40
Aryepiglottic folds	8
Anterior commissure	3

The reports of St Clair Thompson,⁴ Wilkinson,¹⁷ Wilson,¹⁸ Hayes,⁸ and many others are practically in accord with our findings However, Fetterolf's report, based on postmortem observations, is at variance with ours In the eighty-three cases of laryngeal tuberculosis examined, he reports the incidence in the following order 1 Epiglottis 2 Arytenoids 3 Interarytenoid space 4 Vocal cords 5 Ventricular bands 6 Aryepiglottic folds

It is evident from the recorded observations as listed above that the posterior portion of the larynx is more frequently affected—posterior portions of vocal cords, interarytenoid area, and arytenoids

The objective findings that are characteristic of the tuberculous larynx vary with the stage of the disease The pallor often declared to be an early finding is really an unusual occurrence The injected larynx on the other hand is more frequently seen The tuberculous process is rarely limited to one area of larynx The various types of lesions found are infiltration, edema, ulceration, necrosis, fibrosis, and tuberculoma

The infiltration is the early evidence of the laryngeal complication as manifested by thickening and swelling of the submucosa, caused by infiltration of round cells and tubercles, with varying degrees of edema in the subepithelial tissues Such invasion in the interarytenoid sulcus often gives this area a wrinkled and mammalated appearance During this stage, the arytenoids present varying degrees of edema, which, when

extensive, produces the typical pyriform swelling of this structure. This triad of findings, in the cords, arytenoids, and interarytenoid sulcus is a definite diagnostic criterion for the early case of laryngeal tuberculosis.

Ulceration ensues when the tubercles in the subepithelial tissue cascade and break through the surface. The ulcer develops through a proliferation of tuberculous tissue or to edema in submucosa with consequent pressure necrosis of epithelia. When the vocal cords ulcerate, we see the typical mouse-bitten appearance so often described.

Chondritis, perichondritis, and necrosis are evident in the cartilaginous portion of the larynx in advanced cases. This occurrence follows deep ulceration frequently caused by extensive edema with pressure necrosis. The epiglottis involvement, as well as the involvement of the other extrinsic regions of the larynx, has been declared by Thompson to have a very gloomy prognosis. However, we have observed that when the epiglottis is attacked and the other extrinsic regions of larynx are not attacked, the prognosis is not hopeless. We have seen many cases go to complete healing after extensive epiglottic involvement.

Hirsch²⁰ very clearly explains these variations in local pathology of larynx. He describes the alterative, exudative, and productive processes expected in any inflammatory reaction. The alterative process finds expression in the intracellular changes which take place in the structure of the cellular protoplasm and nucleus, such as fatty infiltration and dropsical swelling. With the alterative degenerative changes there occur exudative features where liquid substances of the circulation enter. The next phase of the pathologic process is the emigration of leukocytes, erythrocytes, and lymphocytes which, together with the broken down tissue cells in the exudate, form the anlage for productive inflammation. This is characterized by a proliferation of fixed tissue cells at the site of irritation. Thus, the alterative and exudative processes can explain the infiltration, edema, and ulceration, while the productive processes account for the tuberculous formation and fibrosis.

The reason for the preponderance of

either the exudative or the productive activity may depend on the immunobiologic condition of the organism, the virulence of the virus, and the local tissue structure. Thus, with a very virulent virus and little resistance, we may expect the laryngeal picture to be one of a diffuse, intense edema with ulceration and perhaps necrosis. There is no evidence of any productive changes. This condition would fit into the acute tuberculous laryngitis as classified by Dworetzky.²¹ Pertaining to the local structure, we find that in the region where there is much loose areolar tissue, as in the interarytenoid area and aryepiglottic folds, there is a possibility of much swelling, whereas in cords, ventricular bands, and epiglottis, the extent of edema is much limited.

Manasse²² described four stages of tuberculous involvement of the larynx—infiltration, ulceration, perichondritis, and tumor formation. He accounts for the ulceration as due to the agglomeration of many tubercles under the mucous membrane, cutting off its blood supply and thus causing its death, and exfoliation, and so producing the ulcer.

Fetterolf¹⁰ divides the stages of the laryngeal pathologic process as follows: Infiltration, infiltration with superficial ulceration, infiltration with deep ulceration, and tuberculoma.

It is thus evident that there is little discrepancy in the description of the pathology of the tuberculous larynx. The presence of infiltrative, ulcerative, necrotic or tuberculomatous lesions in a larynx of a patient with pulmonary tuberculosis is readily diagnosed as a tuberculous larynx with little regard for the subjective complaints. Biopsy is rarely resorted to unless there is a question of malignancy. We have found only one case of carcinoma complicating tuberculous laryngitis.

Twenty-one of our series have shown paresis of the vocal cords. Of these, ten showed a complete paralysis and the other eleven only a varying degree of sluggishness. In nine of these cases there was definite evidence of apical tuberculosis on the side of the lung corresponding to the paresis which, very likely, had been responsible for such cord immobility.

The other cases we attribute to local

pathology, either of the cord or at the cricoarytenoid joint

Differential Diagnosis

Those diseases of the larynx, more prone to present difficulty in their differentiation from tuberculosis of the larynx, are chronic catarrhal laryngitis, syphilis, malignant growths, and benign growths. The accompanying table presents the principal differential criteria. It follows mainly a table included in a previous article written by one of us.¹⁰

There is a great tendency for the laryngologist who attends a tuberculosis institution to declare every laryngeal le-

quire a lengthy report. We will, therefore, confine our discussion to the methods most accepted and those employed in our institution.

All of our patients who present any pathology in the larynx are put on vocal rest as a matter of routine. Complete silence, when desired, is most difficult to enforce.

There seems to be some difference of opinion at the present time as to the advisability of vocal rest. St. Clair Thompson, on the one hand, cites a group of completely healed cases treated by this method. He maintains that rest for the larynx is as important as rest for the lung. Kemler,² on the other hand, says

TABLE I—DIFFERENTIAL DIAGNOSIS

	<i>Tuberculosis</i>	<i>Syphilis</i>	<i>Malignant Growths</i>	<i>Benign Growths</i>	<i>Chronic Laryngitis</i>
Hoarseness	Depends on location. Usually early and progressive	Early and progressive	Early and progressive if intrinsic	Depends on location	Intermittent
Sex	Both	Male (predominant)	Male (predominant)	Both	Male (predominant)
Age	20-45	Usually over 20	After 45	Usually over 20	All ages
Early pain	Rare	Frequent	May occur	Absent	Absent
Late pain	Frequent	Frequent	Frequent	Absent	Absent
Vocal rest	Improved by	Not improved	Not improved	Not improved	Improved by
Climatic condition	Improved by dry climate	No effect	No effect	No effect	Worse in bad weather
Dysphagia	Early	Early	Early	Rare	Rare
Odyphagia	Late	Late	Early	Rare	Rare
Constitutional Symptoms	Usual. Depends on extent of lung pathology.	Slight	Late with cachexia	None	Slight
Lungs	Pulmonary tuberculosis	Negative	Metastases here rare	Negative	Chronic bronchitis often
Bacteria in sputum	Tubercle bacilli	Negative. May find Spirochete	Negative	Negative	Mixed infection
Wassermann	Negative	Positive	Negative	Negative	Negative
Biopsy	Tubercles	Gummata	Carcinoma	Benign tumor	Chronic inflammation

sion to be tuberculous. He is too much prejudiced by the presence of the pulmonary lesion, and often overlooks a luetic or malignant condition in this organ. It is not uncommon to find tuberculosis and syphilis coexisting, nor is it a rarity to find a malignant condition implanted on a tuberculous larynx. In fact, the presence of all three have been reported, at different times, in the literature. Thus, it is obvious that the examining physician must always be on the alert for these other conditions which may affect the larynx.

Treatment

To review completely and discuss all the recommended therapeutic measures for the tuberculous larynx would in itself

that "Vocal rest has not served any useful purpose." He feels that the writing necessitated by the regime of complete silence is laborious and depressing to the patients, and that the whispered voice is more exerting than ordinary speech. Wood,¹⁴ rather sympathetic with Kemler's views, feels that what is really wanted in the care of tuberculosis of the larynx is a greater congestion of that organ which is to be expected in ordinary phonation.

We have found, as seems to be the opinion of almost all who are experienced in the care of this disease, that electrocautery is by far the most satisfactory treatment in the majority of cases. However, the indiscriminate use of this therapeutic agent must be de-

pored Lederer and Fishman, in an enlightening paper on the subject of therapy in laryngeal tuberculosis, state "Many methods which have been recommended are successful in some hands but have failed in others because of improper technique and lack of individualization in regard to choice of cases. Discrimination of cases is important in therapy."

We find that there are contraindications to the use of the cautery. These are

1 Evidence of extreme toxicity with high temperature, rapid pulse, and active pulmonary tuberculosis

2 Patients with repeated recent hemorrhages

3 Lesions at the cricoarytenoid to which cautery application would result in ankylosis with restriction of cord motion

4 The acute tuberculous laryngitis—the diffuse, exudative type with or without ulceration.

Wilson, however, has no regard for the general condition of the patient or the degree of advancement of the local condition. In advanced cases with high fever he uses the cautery as a palliative measure and not for an expected cure. We feel that those cases best suited for cauterization are those with productive lesions, localized ulcers, and localized advanced infiltration. Of the forty that were declared satisfactory for cauterization in our series, sixteen showed pronounced improvement, fourteen, moderate improvement, and ten became worse.

Stevenson²³ is not so enthusiastic about the galvanocautery. He says "In my practice I tend to use the cautery less and less, and find the chief indication for its use dysphagia caused by a small ulcer." He mentions the suggestion of E. Tovalgya as a guide for the cautery. The latter, in a doubtful case, effects a simple cautery puncture into larynx. A good inflammatory reaction around the puncture favors the use of the cautery, whereas the absence of reaction or occurrence of necrosis contraindicates it.

With few exceptions our cauterizations are effected by the indirect method. The patient does not receive his breakfast on the morning of this treatment, and is given three grains of sodium amytal four hours before treatment, and another three grain dose one half hour before cauterization. The pharynx is sprayed with

twenty per cent cocaine, followed by the instillation with a laryngeal syringe of cocaine of the same strength about the rim and into larynx proper. The procedure should take about ten minutes, after which the patient waits for another ten minutes and is then ready for the cautery. Three or four punctures suffice for one sitting. A three or four weeks' interval is allowed before again cauterizing the same patient. The cauterization produces vascularization of the lesion with subsequent fibrosis.

Chaulmoogra oil has been extensively used in our hospital. We use it in our cases where there are contraindications to the cautery. We also use the oil in those cases that are suitable for cautery, but only in the intervals between cauterizations. Chaulmoogra oil is employed in advanced cases, more for the palliative effect rather than for its therapeutic value. Dmitry²⁴ has much faith in this medicinal agent and attributes the unfavorable reports to its mixture with mineral oil which he declares injurious. He finds the Chaulmoogra oil bactericidal to acid-fast bacilli, and its end products (fatty acids and glycerin) produce effects which induce local hyperemia.

In cases with dysphagia and odynphagia we resort to the injection of the superior laryngeal nerve. We reach the nerve externally in the space between the upper border of the thyroid cartilage and the hyoid bone. About three c.c. of an alcohol novocain solution are injected (novocain 0.12, chloroform m. 10, alcohol 95 per cent 150, distilled water 80). A severe pain is appreciated in the ear during this procedure. One nerve is injected at a time. All of our fifteen cases requiring nerve injection died.

In cases where perineural injections of alcohol were deemed necessary to relieve pain, it was found that this treatment is not always successful and that its results are brief. It matters not whether the nerve is approached as described above or if the injection is made into the pyriform sinuses. On that account Savitt and Soboroff²⁵ consider the operative approach to the nerve more advisable. Here the nerve is exposed and cut. We hardly believe that this surgical procedure should be resorted to in spite of the expressed simplicity. Bleeding,

great mental strain, and postoperative discomfort are certain sequelae. These patients are frequently very advanced cases, and every consideration should be given to make them as comfortable as possible without resorting to surgery. If nerve injections are not effectual, it is best to resort to morphia and cocaine.

The removal of large tuberculomata may be accomplished surgically followed by cautery at the base. Although we have rarely followed such procedure, we feel it to be a very desirable method. The growth can be removed at one sitting with hardly more discomfort than the cautery produces.

Palliative treatment with sprays are included in the routine care of all our laryngeal cases. An oil spray containing menthol, camphor, and liquid petrolatum is used, as well as a two per cent cocaine spray where the symptom of dysphagia is present.

We have had no experience with heliotherapy at our hospital. The heliotherapeutic agents may be natural or artificial, and may be used locally or generally. Opinions vary as to its beneficial results. Strandberg²⁶ advocates general ultraviolet light (carbon arc). He reports that 113 out of 203 cases treated in this manner were cured, and most of the others improved. He also utilizes the cautery for many of these patients (all ambulatory). Miller,²⁷ utilizing the method of Wessely—a carbon arc lamp impregnated with a special metallic salt given locally by means of suspension laryngoscopy—reports a series of seventy-four cases, of which only two failed to respond. Here again, all his patients were ambulatory, and evidently not very sick subjects. St Clair Thompson does not find any benefit from light treatment. Cemach²⁸ finds that ulcerative processes show greatest improvement with the mercury vapor arc lamp. Underwood²⁹ feels that it is impossible to effect a cure by light treatment, but that it has its place in preparing a patient for cautery. Van Poole,³ having used ultraviolet treatment for about three years, concluded that the good results, if any, are psychological.

The use of radiotherapy has its advocates. Zange,³⁰ with ten years experience with this method, believes it valuable. He finds the cases best suited are those of

a productive nature. A great deal of care must be taken in the administration of the roentgen ray, and the dosage is very important.

Such procedures as thyrotomy and laryngectomy have been resorted to on rare occasions. Curettage has been more or less abandoned. Tracheotomy occasionally must be performed. In exudative lesions where glottic closure occurs, respiratory embarrassment warrants such surgery in spite of our knowledge that the tracheotomy wound may not close. In productive lesions with obstruction, we feel that the indication is the surgical removal of these lesions, if possible, and not a tracheotomy. However, in such a procedure one need be on the alert for the reaction of glottic edema necessitating a quick tracheotomy.

Epiglottectomy is occasionally performed where there is extensive ulceration. We prefer to use the cautery in such cases.

Collapse therapy is now extensively utilized for the treatment of the lung condition, and it is apparent from our own observations, as well as from those reported by others, that it has much therapeutic value to the tuberculous larynx as well. At one time tuberculous laryngitis was considered to be a contraindication to collapse. However, it is now known to have a favorable influence on the larynx. With the knowledge that the involvement of the larynx by the tuberculous process is brought about by direct contact with the sputum, and possibly by the bloodstream and lymphatics, it can reasonably be declared that the collapse of an involved lung reduces the amount of sputum, and in addition removes the lung, to a large extent, from the circulation. The number of bacilli reaching the larynx is in this way greatly reduced. Also, the decrease in cough and expectoration, which accompanies collapse, induces less trauma to the larynx.

Cooper and Benson⁹ treated 196 patients by collapse therapy (pneumothorax, thoracoplasty, and phrenic exeresis) and found laryngeal improvement in 40.6 per cent. They found that a successful collapse was very important, and that the ulcerated larynx did not respond as well as the nonulcerated. Dworetzky³³ reports his observations of 5382 patients treated

by collapse as follows. Only twelve developed the laryngeal complication, of fifty-six patients with laryngopulmonary tuberculosis, the larynx was arrested or cured in twenty-six, improved in nineteen, stationary in five, and unimproved in six. Retrouvay³¹ reports fifty-two cases of which ten were cured, seventeen were improved, eight remained stationary, and seventeen became worse. In this last group almost all the pneumothorax attempts failed. He also reports that in reviewing cases of pulmonary tuberculosis without laryngeal involvement, treated by collapse, it was found that in one out of 400, tuberculous laryngitis ensued.

Stevenson's³² results with collapse were very satisfactory. He observed forty cases, of which twenty-seven were cured or improved, eight stationary, and five worse. All these patients were in a sanatorium, having had the benefits of vocal rest as well as cautery in some cases. Thompson³³ reports nine cases of artificial pneumothorax with complete healing in six. We have treated fifty cases of laryngeal tuberculosis who had collapse therapy, forty-three of whom had pneumothorax, and seven phrenicotomy. The usual laryngeal care was given to all these cases, some of these received Chaulmoogra oil and some, galvano-cautery. Twenty-two were much improved, nine showed a slight improvement, and nineteen became worse. It is thus evident that collapse therapy is a very important aid in the treatment of the tuberculous laryngitis. It is impossible to evaluate the benefit of collapse alone in these cases, since local treatment was not abandoned.

Prognosis

To determine the prognosis of any given case, there are many factors that must be considered. The resistance of a patient, age, previous history, rapidity of onset of the symptoms, type of lung lesion, and the type of laryngeal lesion, are the determining factors.

With regard to the lung lesion, it is known that the more fibrotic the lung pathology, the less severe the laryngeal activity. The cases with soft caseous disease (the exudative type) usually develop an active edematous type of larynx which ulcerates rapidly and is difficult to

control. These latter cases offer a bad prognosis.

A very concise classification with reference to prognosis is presented by Heaf¹¹

- 1 Extrinsic (ulcerative and non-ulcerative)
- 2 Intrinsic (ulcerative and non-ulcerative)
- 3 Localized (ulcerative and non-ulcerative)
- 4 Lupoid (ulcerative and non-ulcerative)

Class 1 includes the arytenoid epiglottic cases—cases with massive infiltration and edema of epiglottis, and pyriform swelling of arytenoids. The lesions usually ulcerate, and the length of life is indirectly proportional to the area of ulceration. In the young adult up to thirty years of age, it is hopeless.

Class 2 comprises the corditic and inter-arytenoid infiltration. Prognosis is fairly good here owing to absence of dysphagia and good response to rest treatment. If there is extension to the arytenoids or ventricular bands, recovery is reduced about fifty per cent.

Class 3 Here, the lesion is confined to one side of the larynx or localized to two small areas on either side. These cases do well.

Class 4 This class is the lupoid type which includes the papillary, glandular, and smooth, defined tuberculomata, and offers a good prognosis.

Thus, the site, extent, and type of laryngeal lesion must be considered in arriving at an estimate of the probable chances of recovery. Also the institution of proper care for the lung condition influences prognosis. Patients receiving care in sanatoria, and especially cases who have received collapse therapy, may be expected to have a fairly good prognosis. Pregnancy, syphilis, and diabetes detract considerably from chances for recovery.

Conclusions

1 Of a series of 1719 patients with pulmonary tuberculosis, 245, or 14.2 per cent were found to have laryngeal tuberculosis as well. The largest percentage of laryngeal involvement is found in the third decade.

2 The sputum laden with tubercle bacilli is responsible for invasion of the larynx by direct contact.

3 Symptoms are of little account as an aid to diagnosis. Hoarseness may not be present in spite of cord involvement.

4 Indirect laryngoscopy is advisable.

both for examination and treatment for patients with laryngeal tuberculosis

5 Objective findings in the larynx are infiltration, edema, ulceration, necrosis, fibrosis, and tuberculomata

6 The electrocautery used with discrimination is, without question, the most effective therapeutic measure available
Chaulmoogra oil is a useful adjuvant

7 The superior laryngeal nerve is in-

jected with an alcohol novocain solution as a palliative measure for severe dysphagia

8 Collapse therapy has proved itself to be very helpful in the successful treatment of laryngeal tuberculosis. Local treatment, however, should not be abandoned

THE BLINDNESS OF TOBIT

Peculiar coincidences are encountered in health superstitions and beliefs. The blindness of Tobit and its cure, as told in the *Apocrypha* is an interesting example, says Charles A. Bahn, M.D., in the *Sight Saving Review*. Tobit, the father of Tobias, while reclining in the courtyard of his home, was struck in the eye by the excrement of a bird flying overhead. Blindness resulted. The recovery of his sight, as quoted from the book of Tobias, is even more interesting.

Chapter 6, Verse 2 "When Tobias went down to wash himself in the Tigris, a fish leaped out of the river, and would have devoured him. The Angel of the Lord told him to take out the gall, and to put it up in safety." Verse 6 "Tobias asked the Angel what was the use of the gall." Verse 8 "As for the gall," said the Angel, "it is to anoint a man who has witten in his eyes,

and he shall be healed." Chapter 7, Verse 11 "Tobias took hold of his father and stroke of the gall in his eyes, saying, 'Be of good hope, Father.'" Verse 12 "And when his eyes began to smart, he rubbed them." Verse 13 "And the whiten fell away from his eyes, and when he saw his son, he fell on his neck."

Tobit's affliction would probably be recognized by the modern eye physician as an ulcer of the cornea caused by the pneumococcus, a germ often found after an injury of the eye by contact with something unclean. The coincidence lies in the fact that bile salts, which are contained in gall, are among the very few drugs which dissolve pneumococci. The use of this same drug for the same infection of the eye is the subject of very recent medical experiments. In short, this new discovery apparently dates back to the cure of Tobit.

ORTHOPEDIC ASPECTS OF POLIOMYELITIS

100 Cases Treated from Onset

ALBERT J. SCHEIN, M.D., *New York City*

Assistant Visiting Surgeon, Bellevue Hospital, Assistant in Orthopedics, New York University Medical College, Adjunct Orthopedist, Mount Sinai Hospital

Object

This work was undertaken with the object of determining the outcome from an orthopedic viewpoint, of the ordinary case of infantile paralysis, when treated under reasonably favorable conditions of medical and other care. A review of such series from the aspects here considered, has not been found in the recent literature. Similar work was done by Lovett and his associates,¹⁻⁴ beginning with the great epidemic of 1916. These workers reviewed thousands of cases under varying conditions and laid down the principles of efficient treatment as carried out today. However, actual statistical proof of the efficacy of this treatment is not clearly stated anywhere.

Selection of Cases

All the cases of acute, subacute, or residual poliomyelitis entering Bellevue Hospital from January 1931 to 1936 were reviewed, amounting to over 400. However, in excluding those not treated from the early stage, those not paralyzed, and those not adequately followed, this number was reduced to 100 cases. The hospital and dispensary records were carefully examined, and where possible recent examinations were obtained. 1931 corresponds to the most recent major epidemic of poliomyelitis in New York.

While a few of the cases in the 100 were mild and rapidly healed, the greater number, by far, were the more severe type, hospitalized for a long period, and followed and treated with the aid of the excellent associations for the aid of crippled children. In Manhattan, most of the acute cases of infantile paralysis are transferred to Willard Parker Hospital during the contagious period. When this is over, the majority of the cases with residual paralysis are referred to Bellevue Hospital, unless they can afford pri-

vate or other institutional care. These cases are then hospitalized as necessary on our special wards under the care of the orthopedic service, and on discharge, are treated in the orthopedic outpatient department. Many cases, especially the mild ones, have failed to return, some have drifted to other clinics or have moved away from the city, as is common in the population of a large city hospital. This series includes only those adequately treated and followed, the majority from one to five years, and includes some of the most severe cases in New York, not actually fatalities, every one being definitely paralytic.

General Outline of Treatment at Bellevue

This corresponds quite accurately to the outline given in A.M.A. Committee report on Poliomyelitis during the 1933 annual session.⁵

The course of this disease may be divided into three stages—the acute, convalescent, and residual. With the first stage, including the febrile, meningeal, and early paralytic periods, we are not concerned here. Our cases were largely referred from Willard Parker Hospital in the early second stage of convalescence.

This stage extends from the stage of paralysis, four to five weeks after the onset of the disease, to approximately two years later, when, as a rule, the maximum muscular improvement has occurred in the paralyzed parts of the body. The residual stage is generally considered to begin about two years after the onset.

Treatment in the convalescent stage includes an early period of absolute immobilization of the limbs or even the entire body. The termination of this period is judged by disappearance of the commonly present muscle hyperesthesia,

From the Orthopedic Service of Dr. Arthur Krida, Bellevue Hospital, Department of Orthopedics, New York University

which often lasts, in varying degrees, three to six months. However, the degree of splintage is mainly determined by the assumption of habitual deforming attitudes and fatigue of the wholly or partly paralyzed muscles. When splints may be temporarily removed, muscle training, massage, and, especially in severe cases, warm pool exercises are begun and carried out daily. All our cases had such treatment in the hospital, and later in the dispensary.

When the recovery has proceeded far enough, especially in the trunk, and the question of ambulation is raised, the same care is required in preventing deformity, stretching of paralyzed muscles and fatigue, as before. This is done by bracing with mechanical apparatus. Cases of trunk paralysis are difficult to splint properly except in bed and these are kept recumbent for as long as necessary to regain their power, even to a year or more. Lovett^{1,2} has maintained that all muscle exercises should be non-weight bearing for one year in all lower extremity and trunk paralysis. This is difficult to do in practice. We therefore use braces or plaster splints where necessary to accomplish the aims of treatment.

The most convenient early splint material is plaster combined with the use of a fracture board. Subsequently, when physiotherapy and exercises are begun, a removable splint is required, and it is then that the danger of deformity is increased. In this series, the prevention of deformity has always preceded in importance the use of massage and swimming pool. Circular plaster is resorted to without hesitation, for periods up to two to three months, above all in foot deformities. In resistant equinus, bivalved plasters have been found inadequate to prevent deformity. To prevent hip deformity, plaster spicas or transverse wings preventing rotation of ordinary plaster leg boots were used, the boots reaching above or below the knee as required.

The type of braces used after the period of absolute splintage is over depends on the location and degree of muscle paralysis. They are frequently combined with some type of removable splint to be used in bed at night. At all times, no hesitation is felt in applying circular plaster again if deformity warrants it.

Braces at best are not efficient in correcting deformity, or even preventing it when powerful deforming forces are at work, but they are the best means short of plaster. During this period the cases are carefully observed with a view to early manipulative or operative intervention, if required, usually after two years in the residual stage.

Procedure

This paper will not deal with the effects of serum or other specific therapy, nor with the individual effects of physiotherapy, swimming pool, or other special treatment. We have selected certain criteria as indicating relative success and failure, notably incidence of deformity, operations required, necessity and types of bracing, and general function especially in the outstanding matter of walking. Our purpose here is to present statistics of our cases in these and other respects.

In addition, in searching the literature, besides the large series of cases reported on in many respects by Lovett et al.,^{1,4} certain other studies were encountered useful for comparison. H. G. Dunham⁷ reported a five year follow-up of 300 cases from the Brooklyn 1916 epidemic. Hatt and Hough⁸ in 1930 reviewed all the cases of poliomyelitis admitted to the Shriners' Hospital at Springfield, Mass. in 1925, when it first opened. These consisted of 116 cases, mainly from rural districts, eighty-five per cent in the residual or chronic stage, fifty per cent untreated, and only ten per cent adequately treated. It is considered that this is a reasonably, but not entirely, comparable series to demonstrate what is to be expected from improper or no treatment, and what is to be expected in a prognostic way in well and poorly treated cases. Wherever possible, and significant, such a comparison has been made.

Statistical Survey and Comment

Incidence by years, age, and sex

The figures in Table I mirror those of New York City, in that 1931 and 1935 were the years of the largest epidemics, with a smaller rise in 1933.

In most cases time in the hospital is a function of the severity of the case, although in some cases parents insisted on

removing their children for home care prematurely. It was of little consideration in these children except at the very height of the epidemic in 1931, when the ward space was needed for only the very severe and most recent cases. Trunk paralysis, demanding long periods of recumbent treatment and under water muscle training, involved the longest periods. Over one-quarter of the cases

were in the hospital for one year or more, receiving their braces and becoming ambulatory to a large extent before discharge.

Thirty out of forty-two of the 1931 cases were followed the full five year period. Practically all of the 1935 cases included in the study, have been followed up to date. Only two cases were followed as little as six months, and in these, though definite palsy had been present at onset, enough recovery had taken place when lost track of to indicate complete cure. Several of the cases are still in the hospital, since the acute stage

Recovery from paralysis

Lovett and his coworkers,⁵ by individual muscle rating, have shown that a large proportion of recovery occurs in most poliomyelitis cases, amounting in the first year to sixty per cent in well-treated cases, and forty-four per cent in poorly treated ones. Legg⁶ has shown that under ideal treatment, this improvement continues at a slowed rate, but progresses indefinitely, even years after the attack, so that, in a selected group of non-operated, well followed patients, at the end of nine years, there was eighty per cent improvement in muscle power in the good cases, but only fifty per cent in the poorly treated ones. In a large number of other cases, in the third and fourth years, Lovett³ demonstrated an actual loss of muscle power, especially in the lower limbs, due to occurrence of deformity, poor care, overuse, and overfatigue. In the individual muscle groups, he has shown that the neck and cranial group becomes practically normal, the trunk becomes normal in over fifty per cent, the abdomen being considerably less likely to improve than the back. Interestingly enough, abdominal paralysis did not affect pregnancy or labor in cases coming to delivery. The arm was found much more likely to recover than the leg, which has only fifty per cent the chance of the former. In the arm, the deltoid is under the most strain, and runs the least chance to recover, the likelihood of cure increasing as the hand is approached. In the lower extremity, the hip muscles and peroneals are most likely to recover, and the thigh extensors and tibials least. When coupled with the high incidence of tibial and deltoid paralysis, this indicates the expected

and actual frequency of certain deformities, i.e., valgus, equinovalgus, and flail shoulder

In this series, the limbs as a whole were considered, subdividing them only into severe and extensive vs. mild and localized paralysis. Fifty-six per cent of our trunk cases recovered entirely, (very comparable with Lovett's 54%) and twenty-four per cent of the lower extremities as compared with fifty-three per cent of the upper. Nearly all the patients improved somewhat, and four-fifths of the trunk and upper extremity cases, and three-quarters of the lower extremity cases improved enough to change groups, that is, to improve from the severely to the moderately paralyzed, or from the latter to the cured group. In one series of over 1800 cases, Lovett demonstrated that both lower extremities recovered equally, but that the right upper recovered more than the left. This is shown in Table II as well, though the figures are too few to hold statistically. He attributed this to the fact that in right-handed people, the right upper extremity gets more active exercise and use, of non-weight bearing or strain producing character, than the left, and likewise both upper as compared to the lower extremities, when ambulation begins. He therefore recommended a prolonged period of non-weight bearing in lower limb paralysis, with long periods of exercises in bed and pool, regarding a year as a desirable minimum.

Deformities

Table III really demonstrates the difference between the good results of proper treatment and the bad in neglected cases. It is a comparison of the incidence of deformities in our series with those in the cases of Hatt and Hough. The difference is evident both in the total number of deformities, the number of patients and limbs deformed, and the number of deformities per patient. In Dunham's series of 300 patients, not personally treated and followed by him, there were a total of 619 deformities observed, an average of 2.1 per patient, and these did not include some of the categories of deformity in the other two groups.

In addition to the quantitative difference in deformities, there was a great qualitative difference difficult to describe.

In the relatively untreated series, the deformities were largely fixed and severe, partly due to time elapsed, whereas, in the Bellevue group, they were often only deforming tendencies with manual correctability. Thus, in the scoliosis cases, the former series had nineteen organic curves, many of severe degree, while the latter series has but ten of which six are still functional curvatures. The remarkable thing is the almost complete absence of severe and very disabling hip flexions, abductions, and knee flexion contractures present in profusion in many of the older series and in all groups of

TABLE IV—OPERATIONS, WHOLE SERIES

untreated cases. This demonstrates conclusively that these deformities are largely, if not entirely preventable. The deformities least amenable to prevention, and most dependent on the presence of unbalanced muscle pull, are seen to be those of flail shoulder, scoliosis, and in the greater number of foot cases. Nevertheless, even in these categories, treatment lessens the number and often the severity of the disability.

Operations

The enumeration of operations and their relative classification in the two series demonstrates again the benefit of treatment in reducing the number of operations to be required, by reducing deformity. This is shown in the total number of operations done, and the number per patient (Table IV). Despite inclusion of operations advised but not yet

done, it is likely that with time, many more operations will be performed on our cases. This applies also to the comparative series of Hatt and Hough, which consists only of the operations on those cases done in one year, 1925, and reviewed in 1930. The relative emphasis, in our series, on stabilizing or arthrodesing bone operations, as opposed to tendon and soft tissue operations, indicates the present trend in most orthopedic clinics in the surgery of infantile paralysis. Although this is not a paper on operative results, it is interesting that most of the tendon operations done here were inadequate in stabilizing the joint or extremity, and required, or will require,

TABLE V—FUNCTIONAL ANALYSIS, AMBULATION

further bone operations to accomplish the purpose *

Ambulatory Function

Table V gives a rough idea of the ambulatory function of our patients as compared with the untreated Massachusetts group. Of the Bellevue cases, there were but four unable to walk about, and eight more required support via the upper extremities, making twelve in all necessitating use of upper extremities in attempts at ambulation, along with braces. Of these four, three succumbed to pneumonia, one and a half to two years after the paralysis, being completely bedridden until death. One case, a quadriplegic, with extensive paralysis in all limbs, fol-

* Since tabulation of these cases there have been done three tendon achilles lengthenings, one tendon transplantation and loop operation, four subastragal arthrodeses, and two biceps transplants. These should be removed from the advised to the completed stage.

lowed for five years, is just standing with braces and upper extremity support. The seven cases walking with upper extremity support are mainly young children learning to walk.

In the untreated series, there were thirty-two cases requiring the use of crutches to get about at all, though fifteen of these are without braces. Eleven of the cases were unable to walk even with support, and were confined to creeping, the wheel chair, etc. Lovett, in one treated series, had 180 cases who all walked after three years, two slightly

Plasters and Braces

Table VI gives a general idea of the types and number of splints used in this series. Little more need be said than is indicated by the figures.

Miscellaneous Statistics

Other figures were also obtained by analysis of the cases, with the results of treatment less striking and more technical in interest.

Trunk paralysis. All the cases with trunk paralysis were examined separately, and nineteen of the severest cases chosen. Of the ten scolioses, four were organic and in one case prophylactic spine fusion was urged. Six cases were functional, but likely to become organic despite bracing. This is in accord with Lovett² who found in recent cases (up to two year follow-up) only a seven per cent incidence, whereas in old cases (three years and up), there was a thirty per cent occurrence of scoliosis. All trunk braces once applied appeared to be required for the full length of the follow-up period despite some muscle recovery in these cases.

Five cases of obviously asymmetric paralysis of the abdomen were present, including two of the organic and two of the functional scoliotics, with one undeformed as yet though braced. This asymmetry is considered one of the main causes of paralytic scoliosis.

Two cases demonstrated the different types of pelvic obliquity—one due to unequal paralysis of the abdominal and posterolateral flank muscles, allowing the corresponding side of the pelvis to droop, the other due to the fixed hip abduction contracture, released by operation.

Upper extremities. The upper extremities were also analyzed separately. Twenty-one were severely enough paralyzed to require splintage. In the end there were ten bad

shoulders, of which two have been fused, and seven more considered to have enough hand muscles to justify this intervention when feasible. Other operations were done on the elbow, wrist, and tendons, but do not warrant individual consideration, except that, even in the upper extremity, the bone operations were most successful. Abduction braces were applied as early as possible and removed in from three to eighteen months, averaging eight and one half months.

Lower extremities. In the lower extremity, examination of muscle paralysis and the incidence of predictable deformity, as a result of overaction of persistent muscles, was seen to bear out the expected in nearly all cases. This was in line with a table of causes of foot deformities given by Lovett.¹ The incidence of the individual deformities is given in Table VII along with a few secondary or postoperative deformities, which were mild. These correspond with those of Hatt and Hough, though they are somewhat less in number. The relation of the type of deformity to the type and number of operations done and advised is given in Table VIII indicating that calcaneus and equinovarus demand operation in practically all cases, and equinovalgus in most, whereas the other deformities are less disabling.

Where seventy-three extremities were braced, forty-five (62%) are still wearing some kind of brace. This is due to the large incidence of fourteen cases with bilateral long leg braces hooked to a pelvic band or back brace, to date.

Conclusions

1 Careful and persistent after-treatment has been again statistically and definitely demonstrated to be of great value in decreasing incidence of deformities and operations required in postpoliomyelitis management.

2 Certain deformities are most difficult to avoid despite proper prophylaxis, notably flail shoulder, scoliosis, and foot imbalances of most types.

3 Gross hip and knee deformities are almost entirely preventable.

4 Even in the unavoidable types, much can be done to minimize the degree of deformity and get early correction where necessary by operations.

5 The three enemies of good function are fatigue, stretching of paralyzed muscles, and deformity.

6 Only four per cent of our cases

were bedridden and totally nonambulatory, and one of these has hopes for the future. There were three deaths.

7 The general outlook in paralytic cases, even of the greatest severity, is never as bad as frequently pictured, and one may be fairly optimistic about the ultimate outcome of the ordinary case.

Case Report

JUVENILE DIABETES IN LABOR

Treated with Crystalline Insulin

BARNETT ALPERT, M.D. and EDGAR A. FERGUSON, JR., Brooklyn

G. P., white female, age sixteen and a half years, known diabetic for six years, has been under crystalline insulin therapy for nine months.

Height was 5 feet 4 inches, weight 163 pounds. Physical examination was essentially negative. Blood pressure throughout puerperium ranged from 114 to 120 systolic and from 70 to 100 diastolic.

Diet throughout entire pregnancy carbohydrates 150, protein 50, fat 40, Insulin 100 units daily.

The duration of labor was thirty-seven hours. For the first twenty-four hours, dosage was increased to 127 units. During the next thirteen hours blood sugar and urine sugar were low and the insulin was withheld, only five units being administered during this period.

A healthy child was born spontaneously, weight was 7 lb 11 oz.

Examination of the blood from the umbilical cord revealed a blood sugar of 130 mg per 100 cc and the blood sugar of the child was 95 mg per 100 cc.

After labor, the patient was again stabilized on the same diet, carbohydrates 150, protein 50, fat 40.

Following shock of labor, on November 13, patient developed acidosis and coma and 173 units of insulin were given. The insulin resulted in relief of symptoms.

On November 14, patient required 100 units of insulin.

From November 15 to 26, patient was adequately controlled with fifteen units daily.

The dose of insulin was increased fifteen units weekly until patient was again stabilized on 100 units daily.

55 E 21 St

The Section on Otolaryngology of the New York Academy of Medicine will hold its October meeting at 8 30 P.M. on Wednesday, the 6th, instead of on the usual third Wednesday of the month. This change of date was made so as to coincide with the itinerary of Professor Maurice Sourdille of the Department of Surgery in the School of Medicine at Nantes, France.

Professor Sourdille will lecture on "New

Technics in the Surgical Treatment of Severe and Progressive Deafness from Otosclerosis, Indications, Choice of Method, and Results. A Report of over Three Hundred Operations." The lecture will be in English and illustrated by lantern slides, and will be prefaced by a foreword and introduction by Dr. Edmund Prince Fowler who, in the absence of Dr. Clarence Smith, will act as chairman of the meeting.

HYPOPARATHYROIDISM WITH PREGNANCY

E A BAUMGARTNER, M D and ALBERT COWLES, A B, M D, *Newark
State of New York, Department of Mental Health*

Chronic hypoparathyroidism may follow surgical removal of the thyroid gland if the parathyroids have been inadvertently damaged. These cases have proven fatal in a number of the cases. In some cases, hypoparathyroidism is temporary, suggesting that enough parathyroid tissue was left which has undergone hyperplasia or recovery of a proper blood supply has occurred to compensate for that lost. In hypoparathyroidism cases, the blood calcium falls while the blood phosphorous rises, which may result in tetany. With proper medication, these symptoms may be relieved. The cause is the important thing in the prognosis. If no parathyroid tissue is left, medication may have to continue as long as the individual lives in order to maintain a normal blood calcium and phosphorus level.

Recently we have seen a patient suffering from hypoparathyroidism occurring about two months after subtotal thyroidectomy. Several blood studies were done and we were able to check these rather closely with the treatment given. While we were following the patient closely with special emphasis on the blood calcium and phosphorus, she became pregnant. Such an occurrence during hypoparathyroidism may be especially dangerous to both mother and offspring. We have found no records in the literature of such a condition occurring.

Mrs K M, thirty-three years old, came in (December 1934) complaining of thumping of her heart, fatigue, and a goiter for about one month. She had a baby about six months old. She had lost about forty pounds since the birth of her child, and was more nervous than she had been. Examination showed a slight uniform enlargement of the thyroid and multiple nodules throughout. The eyes were prominent but there were no other eye signs, and there was a slight tremor. Her pulse was about

ninety-five per minute, but regular. The basal metabolism test in April 1935 was plus fifty. On May 23, 1935, a thyroidectomy was done. The specimen was sent to the laboratory and, on section, a diagnosis of exophthalmic goiter was made.

About two months after the operation, she had an epileptoid attack with frothing and biting of tongue but no spasms, and she was cyanotic. She was seen a few days later by Dr Webb, who questioned the patient and her mother as to symptoms at the time of the attack. He suggested the possibility of a parathyroid deficiency and advised the family physician to continue calcium lactate which he had suggested to him on the day of the attack. She returned September 13 and was sent to us for blood calcium and phosphorous studies. As can be seen in the accompanying table, these figures showed marked disturbance of calcium metabolism and proved the diagnosis of hypoparathyroidism. November 5, she had another attack after which she was given parathyroid extract by hypodermic for several doses. November 27, blood studies were repeated, the calcium was still low and the phosphorous high.

Because of Dr Webb's illness, the patient was turned over to us for care on December 9. On her way home from the laboratory, having had no breakfast, she had another fainting attack but has had none since then. She was given calcium lactate and cod-liver oil as can be seen in the table and asked to return each week. On December 17 and 24, there had occurred definite improvement in the blood calcium and phosphorous. By letter on December 26, she was told to reduce the dosage of medicine, since the calcium had reached 110 mgms and the phosphorous had come down to 49 mgms per one-hundred c c blood.

She was seen only once in January (1936) and again on February 15 when she stated that she had not menstruated in January and was possibly pregnant. Because of the normal calcium (115 mgms) and phosphorous (20 mgms) she was advised by letter to reduce the calcium lactate and cod-liver oil. On March 23, the obstetrician reported to us that the patient was pregnant and wished information on her condition and for us to continue medical care. We saw her again in April and in July

We are indebted to Dr C. W. Webb of Newark, N. Y., for seeing the patient and for his notes on the case. The authors also wish to express their appreciation to Dr C. L. Vaux, Supt. of Newark State School, for many courtesies while following through the course of this patient.

when we felt it advisable to increase the calcium lactate. The patient was then returned to Dr Webb's care and not seen again until November 25 when the baby was seven weeks old. She had gone through a normal pregnancy and delivery and a normal child was born.

Discussion

The diagnosis of hypoparathyroidism after goiter operation is usually not difficult. However, this deficiency is usually made manifest quite soon after goiter operation. In this case, no definite symp-

eight days later (Dec 17) after large dosage of calcium and cod-liver oil, the calcium had returned to normal and the phosphorous had been reduced. After four weeks (January 9, 1936), the blood phosphorous had also reached a normal level. From then on until January 12, 1937, the patient maintained normal levels for calcium and phosphorous under the calcium lactate-cod-liver oil treatment. A normal regular diet was suggested, with one restriction, that two glasses of milk per day be taken.³

TABLE I—BLOOD STUDIES AND TREATMENT

Date	Clinical data	Blood		Treatment
		calcium	Phosphorus	
May 23 1935	Goiter operation			
July 26	Epileptoid attack

Nov. 26				1 teaspoonful daily
Jan. 12, 1937		10 0	4 5	1/2 teaspoonful daily

toms developed for about two months following the operation. However, from the Mayo Clinic,¹ records of a case, which did not begin until two years after thyroidectomy, have been published. These cases may, at first, offer some confusion in diagnosis. Boothby² has stated that post-operative parathyroid insufficiency is infrequent in man.

With symptoms of hypoparathyroidism, treatment was instituted in our case to bring up the calcium level and a reversal of the phosphorous level of the blood. Dr Webb had advised the family physician to continue with calcium by mouth after her first fainting attack July 26. Later, after a second "spell" in November, Dr Webb gave parathormone by hypodermics for a few doses. As can be seen in the table, neither the calcium by mouth nor parathyroid extract had aided materially. This is also proven by the fainting attack December 9. However,

A very interesting thing occurred during the time she was on calcium lactate-cod-liver oil therapy. On February 15th, the patient stated that she might be pregnant, later confirmed by the obstetrician. In October, a normal child was born. From the data, we judge that the pregnancy occurred just about the time her blood calcium attained its normal level. It would be interesting to speculate what would have happened to the pregnancy had the patient not received proper treatment and the blood calcium been subnormal when pregnancy occurred, and what would have happened to the fetus in the later months of pregnancy. With pregnancy, there is a greater demand for both calcium and phosphorous in behalf of the fetus, especially in the later months when ossification begins. The minerals present in a normal diet³ should ordinarily be enough to take care of such a condition. It is difficult to give a diet of high calcium

and low phosphorous It may be better then in these cases to give normal diets, which contain some calcium and then to make up the extra calcium necessary by medication, rather than to increase too greatly the high calcium foods which usually also have high phosphorous content If insufficient amounts were absorbed, however, the pregnant mother would be robbed of her calcium by the developing fetus, with resulting bone decalcification In this case, however, the patient's calcium and phosphorous levels were restored to normal and maintained by calcium lactate and cod-liver oil The vitamin D increased the absorption of calcium in the small intestine In this manner, the calcium demands of a growing fetus were met and the patient was relieved of her former symptoms of parathyroid tetany due to the goiter operation

Summary

A case of chronic parathyroidism due

to a goiter operation was relieved of symptoms by calcium lactate-cod-liver oil therapy A reversal to normal of the calcium and phosphorous content of the blood was brought about Pregnancy, occurring at this time, was carried to full term with the birth of a normal child The patient still continues treatment with calcium lactate and cod-liver oil but in decreased amounts Further calcium and phosphorous studies are contemplated with a view of discontinuing treatment, if possible If not, then treatment along these lines must continue with occasional checks on the calcium and phosphorous content of the blood to maintain them at their normal levels and prevent hypocalcemia from occurring

DEFINITE LIMITATIONS OF FIRST AID"

It is true that we must commend the campaigns to make the public health-conscious and programs to educate laymen how to use first aid methods in treating injuries and disabilities, pending the arrival of a competent physician They have their place if they are conducted cautiously

But it must be recognized that danger lurks in projects which place too much reliance in the knowledge and skill of those who have not had medical training Those who head campaigns involving public education in medical and public health matters and instruction of laymen concerning medical methods would do well to emphasize that there is no substitute for the knowledge and skill of the competent medical man and that self-medication and first-aid by laymen are merely stop-gap procedures, remarks the *Ohio State Medical Journal*

A good point is raised by an Ohio physician who has been taking an active part in instructing first-aid classes of the American Red Cross Although he recognizes the value of this activity by the Red Cross and commends that organization for having utilized qualified medical talent in its first-aid schools, he admits being somewhat troubled by the potential dangers of this and similar activities To quote from his communication

Just how far can the American Red Cross safely go in putting into the hands of these lay people more or less powerful drugs and hazardous technical procedures? The text book advises tannic acid for burns, certain eye lotions, various antiseptics and serum for snake bites Personally I think the text book is very conservative and safe. However already locally these classes are becoming the target for every sort of medicament imaginable They are being circularized in several cases by enterprising drug firms and having no background by which to judge they fall a prey to every nostrum on the market.

Medical societies and physicians individually should give their attention to this problem County medical societies should see that local organizations engaged in medical and public health educational work are made to realize that such work should be under the direct guidance and supervision of trained physicians Efforts should be made to impress on laymen that there is a definite boundary between first-aid and medical service Dangers of over-stepping that boundary should be emphasized As individuals, physicians would do well to warn their patients about dangers of self-medication and encourage them to avail themselves at the first opportunity of the service of a qualified physician no matter how trivial the injury or disability

DIABETES MELLITUS

Short Wave Diathermy and Office Surgery

MARTYN CORNELIUS RATZAN, M A, M D, *Brooklyn*

The management of the diabetic patient in spite of insulin still remains a problem which often defies our all too limited medical control. Particularly, is it so when surgical intervention, especially of the lower extremities,² with its all too attendant limited vascularity and poor resistance to infection, is present. Surgery in a diabetic patient in its present status is usually relegated to one of two realms of therapy, either that of the "laissez faire" school or that of "radicalism." Especially where there are definite roentgenological evidences of calcified blood vessels and definite infective, or even osteomyelitic with osteoporotic evidences of bone, as well as soft tissue disease, is a decision still more difficult.

The problem of limb versus life is all too frequently a matter of rare clinical judgment,¹¹ decision of which may only in retrospect be substantiated or deemed advisable in the future. Since so far as I know the medical and limited surgical treatment of infected processes involved in a diabetic, particularly a total diabetic, or a diabetic complicated with either coincidental blood vessel changes or concomitant pathology of the vascular tree is still a moot question, I should like to submit two cases treated somewhat differently with excellent results to the present writing of this paper.

CASE 1 S, a known diabetic for seventeen years associated with Buerger's disease bilaterally, semiambulatory for past few years. Blood sugar 114.6 mgs per 100 c.c. at time of visit, first seen 11-3-36.⁶ Burn and subsequent infection of left foot and leg after treatment which included venous occlusion, cysteine dressings, surgical removal toe by toe, and then mid thigh amputation April 1935—were all attempted with the end result just noted.

At the time of my first visit, the patient had a ulcer on the dorsum of his right foot about seven inches above the ankle on the tibial aspect which had existed for some months, there was no dorsalis pedis or posterior tibial pulsation present. The extremity was cold and there was delayed venous return. The ulcer was circular with jagged

inner surface and a⁹ necrotic infected base, appearing grayish black in hue. There was no sensation of this leg of a epicritic or even protopathic nature. Practically no free bleeding on curetting this ulcer bed could be obtained.

A debridement of the ulcer was done that evening, at home. Hot wet magnesium sulphate solution, hypertonic in nature (one tablespoon of the salt to a glass of hot water) was applied for twenty-four hours following. X-ray of the foot corroborated clinical impression of only soft tissue involvement and no bone pathology.

Short-wave diathermy³ given daily for fifteen treatments with a wave length in the neighborhood of twenty meters for fifteen minute intervals starting with application to the big vessels of the thigh, then reapplication just below the knee and finally a third, around the ulcer—a total of forty-five minutes was used. Dry dressings were applied for about one week followed by a split cod-liver oil ointment. Then a one per cent cysteine ointment to increase fibroblastic activity was applied during the duration of the diathermy treatment. Bathing with saline, dry dressings, and adhesive strapping bridged across wound to stimulate epithelialization followed. Healing of this indolent ulcer followed rapidly.

CASE 2 A W, fifty plus in age, complained of swelling and pain in second toe, middle joint of the right foot. Diabetes mellitus with insulin injection have been present for years. Blood pressure 178/110. Aortic and mitral systolic murmur of the heart were present. Liver, two fingers below costal margin, cyanotic lips, dyspnea, and venous engorgement of the neck in a semireclining position were present at the date of my first examination December 17, 1936. There was no dorsalis pedis or posterior tibial pulsation of either leg. Over the junction of the second and terminal phalanx of the second toe of the right foot there was a small sinus crepitus on movement and tenderness on lateral compression to this middle phalanx was present. Short-wave diathermy¹⁰ for two weeks daily treatment of three applications of the same nature as case 1 was done. Positive x-ray findings of osteomyelitis of the phalanx of this toe was present at this time.

Since warmth⁴ of the leg had returned

to a large extent as had sensation of an epicritic nature and there was an increase in bleeding on scraping the bed of the ulcer deliberately, incision and drainage of this infected area with a scraping of the nail bed and bone was done. Rubber dam was inserted and the wound packed with cod-liver oil ointment and kept open for five days¹. The drain was removed and cysteine (one percent) ointment was put in its place. Healing followed. Blood sugar at this time was 236 mgs percent. Insulin ninety-five units per day 50-10-35. The patient was re-x-rayed March 13, 1937 (about three months after first x-ray). The osteoporosis of the bone was gone and healing of the pathological fracture which had existed as result of this previous osteomyelitis was observed. The periostitis was gone. Superficially the previously existent sinus leading down into the bone had disappeared. The lateral tenderness on pressure over this bone was gone completely. The foot itself is much warmer and more sensitive⁶ to touch and pain sensation. Venous return is more efficient and complete.

Conclusions

1 Diabetes mellitus if controlled by insulin and diet, blood chemistry and urine examination periodically determined, is in itself no contraindication to surgical intervention extra "hospitally done"

2 Circulation of the extremities can be immeasurably increased by short-wave

diathermy suitably applied, the mode of which consists of starting with the larger trunks and proceeding downward hoping to increase collateral circulation and also dilate the atherosclerotic vessels. The meter length used is preferably of the longer wave length. Ultra short wave in the region of below ten meters was found to be in the hands of the author not quite as efficacious when compared with apparatus⁷ in the neighborhood of twenty meters.

3 Conservative office surgery if the patient is properly prepared may be done with justifiable hopes of success. This may afford even the impecunious patient adequate surgical treatment at an economical saving and the doctor a chance and facility for treating such patients which he might otherwise be denied due to necessity for hospitalization or more radical surgery.

HOW HYGIENIC MARRIAGE LAWS WORK

It is not at all surprising, says the *Detroit Free Press*, to find that, with the advent of the new hygienic marriage law in Illinois, numbers of young people are traveling across the state lines in search of "cheap and easy" weddings in states as yet officially indifferent to the ravages of syphilis.

The same sort of thing happened in Connecticut after medical examinations certifying that candidates for matrimony were free from venereal infection became mandatory under the law.

But in the end the regulation worked out well, because a Connecticut wedding grew to have a special value.

It was a guarantee of safety from a fear-

ful disease, both for the benedicts themselves, and for future children.

There is every reason to suppose that this will be so later on in Illinois, and in Michigan, especially after fugitive weddings begin to be suspect.

And they are bound to become so when the reason and necessity for hygienic laws are better understood among young people, many of whom now have little knowledge of the prevalence and devastating nature of the disorders from which the state is trying to protect them.

It is probable, too, that the time when all except the most backward states will have hygienic marriage laws is not far ahead.

Today's successful physician is the one who refuses to be blinded by too much the-

ory and ultra-scientific methods—*The Ohio State Medical Journal*

STREPTOCOCCUS HEMOLYTICUS INFECTION TREATED WITH SULFANILAMIDE

WILLETTTS W GARDNER M D, *Patchogue*

This is to report the use of sulfanilamide in a case of Streptococcus Hemolyticus Empyema of the pericardium, without incision and drainage, with a myocarditis, endocarditis, three separate attacks of lobar pneumonia, a pleurisy with effusion, and an abscessed tooth

Case Report

On December 26, 1936, I was called to see an eighty-two year old grandmother. She had a discharging, acute, purulent otitis media of four days' duration, with more or less pain. I had been called because she had, on the opposite side of the face from the infected ear, a small blistered area caused by picking a small pimple. It was a beginning erysipelas, a streptococcus infection from the ear, and in spite of heavy doses of streptococcus antitoxin, she died in five days.

On December 27, I also saw nine year old A.K. He had a slight rhinitis, pharyngitis, and tonsillitis, with a temperature of 101. His throat was painted and he was given throat gargles and salicylates and kept in bed. In four days the temperature was normal and he was better. After carrying a normal temperature for one day, he was allowed downstairs on the couch. On January 2, the beginning of sixty days of serious illness, I was called again.

My general impression was that he was very sick but except for a slight redness of the nose and throat, the examination did not reveal anything definite. The T-P-R was 100, 120, 28. The striking thing, however, was the rapid pulse in proportion to the temperature, as he was not of the nervous type. The following day the temperature was 102, pulse 130, respiration 35. I then called in Dr David MacDonell, a pediatrician. We could not detect any abnormality of the heart and lungs at that time. So, thinking that he might have a posterior nasal or sinus infection, we treated him accordingly but he became increasingly worse. On January 5, the fourth day, the respiration was 40, pulse 132, tempera-

ture 101.2, and the physical examination revealed the heart enlarging as is shown in Fig 1. There was also pain in the left shoulder.*

This day, a report came back from the New York State Laboratories that they had found Hemolytic Streptococci in the throat culture. A definite diagnosis, therefore, was a Hemolytic Streptococci heart infection. The following day I obtained for the first time, a definite pericardial friction rub over the whole precordia. On January 7 a definite right upper lobe pneumonia appeared. Oxygen was started by nasal catheter and continued for the next forty-one days. In consultation with Dr MacDonell, it was decided to use Prontylin and Prontosil. This was ordered directly by telephone from the Winthrop Chemical Company in New York City and the dose advised by them obtained. On January 8, the day the treatment was begun, the temperature was 105.5, pulse 160, respiration 50, the child was delirious and it seemed as though he could not last much longer. The doses of Prontylin and Prontosil are noted on the accompanying table.

On January 11, seventy-two hours after beginning treatment, the temperature came down to normal pulse 120, respiration 45. January 12, pulse very weak at 150—no friction rub heard but the cardiac dullness enormously increased. A pericardial effusion was apparent (Fig 2).

This x-ray also shows a shadow of the resolving upper lobe pneumonia on the right side. On January 16, with a continued feeble and rapid pulse and rapid respirations, Dr L. H. Bauer, a cardiologist, and Dr MacDonell, were called in and 500 cc of a dirty, brown, purulent fluid was withdrawn from the pericardium by Dr Bauer, going in outside the mammary line in the fifth interspace. The report from the New York State Laboratories stated that the fluid contained a pure strain of Hemolytic Streptococci. Under the micro-

*All x ray pictures were taken with a portable machine from the x ray department of the Suffolk County Sanatorium, and interpreted by Dr Edwin P. Korb, the head of the institution.

scope it was a dense mass of pus cells, which had to be diluted with water in order to separate them individually. His white blood cells count was 30,000, with Polys at eighty-seven per cent. Throughout this long illness, teaspoonful doses at a time, of liquids and soft foods was all that could be given, as the respirations were so rapid that nourishment had to be taken quickly.

Following the tapping of the pericardium, an upper left pneumonia developed, with a pleurisy with effusion (Fig 3). This picture did not quite get all the apex as he could not be moved from his side. On January 18, 250 cc of a clear fluid with only an occasional pus cell was withdrawn from the left lung by Dr E R. Hildreth. The removal of this small amount of fluid could be noted by the stethoscope and percussion, and also by a slight easing of the patient's respirations.

On January 22, the upper left pneumonia cleared and by January 24, the respirations were down to 28. On the 26th, an abscessed

tooth developed which drained through the large cavity in the first tooth. There was a slightly increased temperature with this.

The patient then went along fairly well for a while until February 1, when the pulse went up to 160, temperature began to go up, and the respiration was 42. Again flatness and bronchial breathing were noted in the left upper lobe, although heart sounds were louder, pulsations could be felt through the chest wall, and a systolic murmur was heard at the apex. Blood culture negative. On February 11, x-ray showed a pneumonia on the left side—a complete shadow, not enabling one to distinguish the heart. (Fig 4) The boy had not, for some time now, been able to turn from his left side. Because of the duration of the pneumonia, on February 13 I called in Dr Edwin P. Kolb, whose diagnosis was an unresolved pneumonia. By February 18 this began to clear, there was less consolidation and more rales. He was able to move to his back, oxygen was stopped, and cardiac

pulsations could be seen through the chest wall. By February 26, he could sit up in bed but was still running a slight temperature. There were still a few signs in the left upper lobe, but not, I thought, sufficient to keep up the temperature. There was some resonance at the apex for the first time, a faint bronchial breathing, many fine rales on inspiration, and a loud systolic murmur. Fig 5 shows a remaining consolidation with some thickened pleura. The heart was smaller than it was in the first picture, before filling up of the pericardium and was not far from normal size. There is an enlargement of the liver also. I decided to increase the Prontylin to the maximum dose of two gms for his estimated weight of forty lbs. The temperature promptly went up. On March 1, Prontylin

Fig 5

Fig 4

was stopped. The temperature came down to normal on March 3, respiration 28, pulse 120, the end of his temperature and long illness.

Fig 6 (March 8) shows very slightly more clearing of the left lung. His recuperation was remarkably rapid. By March 27, the pulse rate was normal and there was no systolic murmur. He was walking around and his mother found it difficult to keep him from being overactive.

The final x-ray (Fig 7) taken April 7, when he was up and about, shows lungs normal again, the heart slightly enlarged. Since the end of April, he has been playing around all day, playing baseball, riding bicycles (against orders), without any signs of shortness of breath, decompensation or heart pain. On June 4, except for some heart enlargement, he was as active and well as before his illness.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, D R P H, *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Parents Don't Know

A young man belonging to the theatrical world began to feel "indifferent to life," "nervous" and was afraid his heart was "going to fail" him. He had a number of other mild psychoneurotic complaints. The parents sent him to a physician whom they knew, but he wanted to be "smart" and judged that a doctor recommended by the old people must be an old-fashioned fogey and could not be good. He, therefore, in order to be modern, called up the official bureau for medical information in his city and to his amazement the same name was given to him as the proper medical man for his ailment. This detail gives the reader an idea of the patient. Indeed he despised everything his parents did except their constant payment of his bills. That was the cause of his inner conflict. He hated his parents, but needed them. He thought them slow and inefficient, but they had achieved great success while he had accomplished nothing.

A conflict, an undesired and unexpected conflict, is like the collision between the

boat and the landing pier. The shock is wisely softened by a cordage mat. In the same manner we must find the means to break the mental blow.

The doctor went over the details of this patient's life with him. It was found that his contempt for his elders dated from his college days and was a contagious imitation of other boys' habits. It was simply stylish to have one's parents in contempt, although they were feeding these young men. Besides, these particular parents had earned even more disdain because of their mean practice of telling the truth, yea, even the most unpleasant truths.

Our patient recognized his mistake and barring a deep-seated, universal, and natural hostility between parents and children, he had no real reason for hating his father and mother. Then adjustment took place and he accepted the temporarily subordinate position given to him in the theatre field. Of course, he also had to promise to give up the great excess of whisky drinking in which he was indulging.

Baker or Artist?

In my medical career I have seen and discovered and encouraged many artists, most of them in early childhood.

One boy of eight was interested in the large oils and color reproductions of my waiting room, but he looked with an extraordinary curiosity at the sketches of long ago made by myself and hanging in my desk room. While his mother and I were in the examination room he stole one of my drawings, and, although he hid it close to his chest, his mother noticed it. He cried "I took it 'cause 'cause I liked it." Of course, I was proud. There was at least one admirer. After his departure I also missed a little bronze bust and I suspected the same child. The main fact was the impression with which I remained that he was an art lover.

For the next ten years I saw him a few times as a patient having small physical ailments. But at the age of eighteen he was brought to me as suffering from mental depression. At the basis of his psychosis was a conflict between him and his parents. They wanted him to learn to manage the modest baking shop which they owned, while he de-

sired to study art. He was "sure" to become a great painter.

I was chosen as the arbiter because of another case which had become known and in which I had succeeded in having the child get the proper art education and in bringing out her splendid talent.

The young man's work was shown to me. I did not like it and I said so. Both parents triumphed. He will be better as a baker. But I could not see it their way. I told them that giving their son an opportunity to try his luck may be his only remedy, his only chance to recover from his mental disturbance. They followed my advice, he entered an art school and the result was as I predicted.

He was mentally healthy and successful and in later years made much money producing portraits that pleased the man in the street, but which I would never consider art. Indeed I was badly disillusioned.

If however I had to fight for anyone's freedom to adopt an artist's career, notwithstanding my personal unfavorable opinion of his talent, I would do it again.

611 W 158 St.

Comment

The reason for reporting this case is that I know of no similar one. Empyema of the pericardium alone, no matter what the organism, demands incision and drainage for a fifty per cent chance for life. Those who do recover are often crippled with an adhesive pericarditis which may necessitate another operation. The outcome for those not operated is usually fatal. With a *Streptococcus Hemolyticus* as the invading organism, involving the pericardium, myocardium, and probably endocardium, with the three distinct pneumonias—one long drawn out before resolving, and with a complete recovery—the case is unusually interesting.

In regard to the use of Prontylin and Prontosil, not until the third day of its use did I find the first work published¹ in this country on Para-Amino-Benzene-Sulphonamide (sulfanilamide). This was a guide as to dosage and what to expect in the way of complications. However, it was rather difficult to estimate the boy's weight as he had weighed 53½ pounds at school and had been ill the week previous, so I estimated the weight at fifty pounds at the beginning of his illness. It was not long before he was just skin and bones and I then judged it to be about forty pounds. From January 22 to 23 I had to wait for a new supply of Prontylin but then de-

cided not to use it again until January 26, when the abscessed tooth appeared with the fever and I began giving a little more. From then on, it was not stopped until March 1. An interesting point was on February 26, when I increased the Prontylin, then stopped it, with the temperature returning to normal. It would seem to show that the last few days of temperature were due to the sulfanilamide, or else the increased doses destroyed the remaining infection.

As for other medications, he was given some salicylates and iron when I discovered that the hemoglobin had dropped quite low, and small doses of digitalis. The latter, I know, was a debatable thing to do but on an occasion when I stopped it, the condition was bad, the pulse rapid, weak, and imperceptible. He was given bicarbonate of soda at times but never any cathartics.

Conclusion

I feel that this is just one more case proving the effectiveness of sulfanilamide in the treatment of *Streptococcus Hemolyticus* infections—to say nothing of the good reports being published on its use in other kinds of infections.

TRUST NO SLUR IS MEANT

"Well-educated Young Lady requires position as Secretary-Receptionist to doctor,

dentist, or gentleman" —*Advt in the London Times*

ficers for the district, analyze the causes of this disappointing result. Higher rents in the new dwellings and additional transportation costs reduced the tenants' already minimal allowances for food. The resultant nutritional impairment weakened their defenses against disease and death.

As Hugh H. Darby, writing for *The Nation*, states, "The solid fact brought about by this study is that people living in slum housing earn so little and live so close to the margin of starvation that it is impossible to raise their rents or other living expenses in any way without seriously affecting their nutrition." This has long been one of medicine's principal arguments against compulsory sickness insurance. The class which this system is supposed to benefit cannot afford the price, i.e., diminished weekly income and higher living costs. What good is it for the government to extend second-rate medical service with one hand, when with the other it carves a big slice out of meager budgets to pay the bill?

"The Arbitration Way"

The principle of arbitration has again proven its value in workmen's compensation. Conference and discussion have adjudicated numerous disputes which would formerly have gone on to costly, protracted litigation. Of 2500 contested bills, many have been amicably settled by talking things over in an atmosphere of good will. More controversial cases have been placed on the formal arbitration calendar, where they will be disposed of promptly.

Contested bills are not the only disputes to be settled by arbitration under the amended Workmen's Compensation Act. Charges of "case lifting" are heard and, if substantiated, bring redress to the plaintiff. On any important point of difference arbitration gives both carrier and physician an opportunity to appeal at small expense to an impartial, well-informed body.

It is not to be expected that under the new law the carriers have suddenly become imbued with a desire to pay more than a minimum for medical service or loosen their grip on this aspect of compensation. Organized medicine must continue to fight without let-up for fair fee schedules, free choice of physicians and the supremacy of medical judgment in medical questions.

Insofar as agreements exist on certain points, however, arbitration affords a fair, intelligent means of adjudicating disputes. Not only does it produce quick settlements at low cost, but, in the process of ironing out disagreements, it clarifies issues and sometimes points the way to the prevention of similar controversies.

Needless to say, the results of arbitration could not have proven so satisfactory without a spirit of cooperation and fair play on the part of all concerned. The participating physicians, carriers, and state officials have shown that it is entirely feasible to rely on good sense and good will for the settlement of industrial disputes.

The Anti-Pneumonia Campaign

The Medical Society of the State of New York has instituted throughout the state a number of what they have been pleased to term "pneumonia institutes." Unfortunately, because of the lack of available facilities those desiring to avail themselves of the facilities of these institutes will have to apply early—because of the usual rule of "first come, first served," and when the facilities of a given institute are exhausted, those applying later will have to be taken care of in some other way at some other time.

The ravages of pneumonia are the enemy which these institutes are preparing to combat. A word to our membership should be sufficient to enlist their active participation as far as our facilities permit. There are, in these institutes, the combined efforts of the Medical Society of the State of New York, the

The District Branch Meetings

The resumption of activities after the vacation days of the summer are usually signalized in our Society by the District Branch Meetings. They serve a three-fold purpose. They bring the high officials of the State and the component county societies in contact for the exchange of views, they permit a discussion in detail of the program outlined at the last annual meeting, and clarify moot questions on pending issues, and lastly they afford the means, through their scientific programs, of carrying on our ever-present endeavor to improve the quality of medical practice which we deliver to the people of this state.

Some of the District Branches have already held their meetings—but there are more to come—and we issue this note with the idea of calling attention to the exceptional scientific programs which the District Branches are presenting, and the opportunity their meetings afford.

It was thought at one time that these branch meetings might be abolished in the interest of economy, but when weighing the costs in dollars and cents against the incalculable gains to the profession and to the solidarity of the State Society, it was wisely determined to continue them. The character of the work pre-

sented this year is evidence of the wisdom of the decision made by the House of Delegates. We suggest that you visit your District Branch Meeting, meet your officers, talk your problems over with the state officials—and last but not least—make those social contacts which are invaluable in the practice of medicine anywhere.

A Timely Warning

English experience with slum clearance holds a valuable lesson for American sociologists who desire to combat the adverse influence of poverty on health. It lends strong support to those who insist that proper nutrition is a primary factor in the maintenance of health. Health schemes which diminish the amount of money available for food in low income families defeat their own purpose.

In Sockton-on-Tees an abnormally high death rate prompted the demolition of a large slum area. Its inhabitants were transported to a model housing development in the confident hope that mortality would thereupon diminish. To the disappointment of all, the death rate not only failed to drop but actually increased.

In *Poverty and Public Health*, G C M M'Gongle and J Kirby, health of-

CURRENT COMMENT

October 1, 1937]

"The town meeting offered \$1,200 annually plus free rent in a large house, and the doctor can keep whatever he makes on the side.

"The last physician, Dr Leon Hagopian, left to enter the medical corps of the army at Fort Williams, Portland, Me. Many of the roads in this town (Petersham, Mass.) of 800 persons are impassable at times in Winter and physicians have been unable to come from Athol and Gardner.

"Speakers at the town meeting agreed there were not enough patients to provide independent support for a general practitioner. For his \$1,200 the new doctor will act as school physician, which duties are not arduous."

"I HOLD EVERY MAN A DEBTOR to his profession, from which, as men of course do seek to receive countenance and profit, so ought they of duty to endeavor themselves by way of amends, to be a help and ornament thereunto"—The Polk County *Medical Bulletin* reminds us that "thus spoke Francis Bacon."

"DECLARING THAT 'IT WAS THE SPIRIT of help and human sense of duty to your people and your God that inspired the great men of our country,' United States Senator Harry A. Moore says he hopes that 'the Government will never get to the point where it would curb such ambition and spirit.'"—According to *The New York Sun*, of September 16, from which we have quoted the above, Senator Moore made these remarks before 500 persons at the thirtieth annual banquet of the American Hospital Association which has been meeting in Atlantic City.

"THE CURRENT VENEREAL DISEASE campaign represents both an opportunity and a challenge. Those of us who are in sympathy with the objectives of the move and who wish to handle venereal cases must im-

prove our ability to diagnose and to render treatment. If the campaign is not to peter out entirely, it is imperative that the public be given the best care of which modern medicine is capable.

"This means taking a special interest in venereal work and devoting the necessary extra time to it. How to do this requires little explanation since lectures on the subject are being given throughout the country, medical centers are holding postgraduate courses, and there are numerous charity clinics in which to obtain clinical experience"—From *Medical Economics* of September

"THE RADIOLOGISTS OF THE WORLD met in Chicago last week and in a hundred recondite scientific addresses drove home the enormous progress made in alleviating disease by means of invisible radiations.

"To philosophically minded physicists who are trying to burst atoms asunder and fathom the mystery of the cosmic rays the addresses delivered in Chicago are of more than medical significance. Light and life—there has always been a mystic relation between the two. Even the physical relation has long been obvious.

"The healers in radiology are blazing trails that will make it necessary still further to revise our notions of matter and life. There was no place for mind in the universe as it was conceived by science in the last century. Life was a nuisance to a physicist. It did not bend readily to his laws of nature. But since the x-rays and radium were discovered, since in explaining them it has become necessary to treat the universe as if it were in part created by the mind, the physicist has lost his old cocksureness. Physics and medicine reigned like a king and his queen at Chicago. Out of their union there is bound to come a deeper understanding of man's place in the universe though the immediate object was the realistic treatment of human suffering."

—From *The New York Times* of September 19

The next examinations (written and review of case histories) for Group B candidates will be held in various cities of the United States and Canada on November 6, 1937, and February 6, 1938. Application for admission to these examinations must be filed on an official application form in the office of the Secretary at least sixty days prior to these dates.

The general oral, clinical, and pathological examinations for all candidates

(Groups A and B) will be conducted by the entire Board, meeting in San Francisco, Calif., on June 13 and 14, 1938, immediately prior to the meeting of the American Medical Association.

Application for admission to Group A examinations must be on file in the Secretary's Office before April 1, 1938.

For further information and application blanks address Dr. Paul Titus, Secretary, 1015 Highland Bldg., Pittsburgh, (6), Pa.

State Department of Health, and the practicing doctor—a combination ideal in any health program

Toxicity of Barbituric Acid Compounds

The widespread use of the various derivatives of barbituric acid either as sedatives or anesthetics has lulled the profession and the public into the belief that they are using harmless and nontoxic drugs. That the reverse is true has been demonstrated by recent pharmacological studies of the various barbitals.

Amytol, which is recommended for intravenous analgesia, is capable of producing a ganglionic paralysis of the cardiac vagi. The action may spread to inhibit such protective reflexes as vomiting and coughing.¹ Cyanosis, skin eruptions, reduced peristalsis and depressant action upon the gastrointestinal tract have also been recorded.² Evipal, one of the barbiturates now extensively used for short anesthetics, may cause a destruction of the erythrocytes with a resultant anemia.

Such toxic manifestations render the use of these drugs dangerous except in the hands of the most competent. The number of people who use the barbitals for sedative purposes is increasing. They are the ones who should be warned of the side actions of these drugs, and if necessary be prohibited from obtaining them except upon the written direction of a physician. The indiscriminate use of the barbitals for surgical anesthesia is also to be condemned. A clinical study of each patient is indicated and the selection of the one to whom a barbitol is administered should be made with extreme caution.

Aero-Otitis Media

The increased growth of commercial air transportation has brought in its train

a new occupational disease called by Armstrong and Heim¹ "aero-otitis media." It is a traumatic inflammation of the tympanic cavity caused by the difference in pressure within the middle ear and that of the surrounding atmosphere. Failure to voluntarily open the Eustachian tube or inability to do so during flight brings on this condition.

In the acute forms, a sensation of fullness in the ears accompanied by a degree of deafness and tinnitus is noted. During the descent of the plane, severe pain is experienced, and vertigo and nausea are often present. Rupture of the ear drum occurs when the mercury pressure is between 100 and 500 mm. In the chronic cases, there is a partial loss of hearing and a sensation of stuffiness in the ears. The membrana tympani becomes dull and retracted.

The occurrence of aero-otitis media can in most instances be avoided by the proper knowledge of how to periodically open the Eustachian tube by yawning, swallowing or autoinflation. For the lesion itself, copious douching of the ears with water at 110 F followed by dry heat relieves the acute pain. Gentle inflation of the Eustachian tube and frequent shrinking of the mucosa about the ostium should also be used.

This condition will be met with more frequently by the profession as air travel increases, since passengers are exposed to the same influences as are the pilots during flight. Physicians therefore should familiarize themselves with the prophylactic measures so as to instruct those of their clientele who contemplate traveling by air.

CURRENT COMMENT

"TOWN TO PAY FOR DOCTOR, VILLAGE without a physician will give salary to willing man" is the statement which heads an interesting news item to be found in *The New York Times* of August 9. We quote "This town without a physician since January, voted at special meeting to pay a doctor to come here and live."

² Dallemagne, M. J. *Arch Internat. Med* *Exper*, 10:379, 1935.

¹ Armstrong, H. G. and Heim, J. W., *J.A.M.A.*, 109:417, 1937.

DISTRICT BRANCH MEETINGS

First District Branch, October 5

Place of meeting The New York Post-Graduate Medical School and Hospital is located at 20th Street and Second Avenue, New York City, with the main entrance at 303 E. 20th Street. All sessions will be held there, except those given by the Department of Dermatology and Syphilology, which will be held at the N Y Skin and Cancer Unit of the Post-Graduate, with entrance on Second Avenue near 19th Street.

Parking Arrangements have been made with the Police Department to restrict parking from 9 to 5 on this day on the blocks between Second and First Avenues on 19th, 20th, and 21st Streets to the cars of physicians attending these sessions. Policemen will be detailed to supervise the parking.

Luncheon A buffet luncheon will be served at 1 P M, in the recreation room on the first floor of the Nurses' Home, with entrance on 20th Street across from the Hospital.

General session From 2 to 3 P M, a general session will be held in the Erdmann Auditorium. An address of welcome will be given by Dr Willard C Rappleye, Director of the New York Post-Graduate Medical School and Dean of the College of Physicians and Surgeons, Columbia University. Addresses will also be given by Dr W C Buntin, President of the First District Branch of the State Medical Society, and by Dr Charles Goodrich, President of the Medical Society of the State of New York.

Visitors in clinics Those who wish to attend the sessions which take place in outpatient clinics are advised to come a little in advance of the hour named as space limitations require that only a few visiting physicians be admitted to each clinic.

Dermatology and Syphilology

(Entire program at the N Y Skin and Cancer Unit at the corner of Second Avenue and 19th St.)

9:00-10:00—"Diagnosis and Treatment of the Most Common Skin Diseases," illustrated with lantern slides. Dr Joseph L. Morse.

10:00-11:00—"Physical Therapy in Dermatology, Exclusive of X-rays and Radium." Dr Henry D Niles.

11:00-12:00—Demonstration and Discussion of Patients with Diseases of the Skin. Dr J Frank Fraser.

12:00-1:00—"The Cutaneous Manifestations of Early Syphilis," illustrated with lantern slides. Dr E W Abramowitz.

2:00-3:00—"The Cutaneous Manifestations of Late Syphilis," illustrated with lantern slides. Dr Fred Wise.

3:00-4:00—Demonstration and Discussion of Patients with Diseases of the Skin. Dr George Miller MacKee.

4:00-5:00—"The Treatment of Syphilis." Dr Max Scheer.

In addition to the lecture schedule given above, there will be rounds of the clinics for groups of physicians, eight of each group, beginning every hour on the hour. All the skin and syphilis clinics in the N Y Skin and Cancer Unit will be visited.

Gynecology

9:00-10:00—Lecture. Subject to be announced. Dr Gerard L Moench (Room 100).

10:00-11:00—"The Importance of a Urological Investigation in Gynecological Patients." Dr Isador W Kahn (Lantern slide illustrations) (Amph B).

11:00-12:00—"The Glandular Aspects of Gynecology." Dr Thomas H Cherry (Amph B).

12:00-1:00—"The Etiology, Diagnosis, and Treatment of Arrhythmic Functional Uterine Bleeding." Dr Theodore Neustaedt (Amph B).

2:00-6:00—Operative Clinic. Dr Walter T Dannreuther (Room 4).

Medicine

9:00-12:00—Case Demonstrations in Gastrointestinal Clinic. Dr Z Sagal.

9:00-12:00—Case Demonstrations in Arthritis Clinic. Dr E F Hartung.

2:00-4:00—Case Demonstrations in Diagnostic Clinic. Drs M A Bridges and David S Likely.

2:00-4:00—Case Demonstrations in Metabolic Clinic. Dr James J Short.

2:00-4:00—Case Demonstrations in Vascular Clinic. Dr Irving S Wright.

2:00-4:00—Case Demonstrations in Chest Clinic. Dr Julia V Lichtenstein.

3:00-3:30—"The Evaluation of the Cardiac Patient as a Surgical Risk." Dr Charles A Poundexter (Erdmann Auditorium).

4:00-5:00—Medical Staff Cases. Demonstration of Medical Ward Conferences. Dr Walter G Lough and staff (Erdmann Auditorium).

The Department of Medicine will also have on display in Room 100 an Exhibit prepared by the Division of Gastroenterology. Demonstration on Colitis including colored drawings through the sigmoidoscope X-rays and amebae and other parasites.

Neurology and Psychiatry

10:00-11:00—"The Management of the Psychoneuroses in General Practice." Dr Philip R. Lehrman (Erdmann Auditorium).

11:00-12:00—"Head Injuries." Dr George A Blakeslee (Nerve Clinic).

12:00-1:00—"Encephalograms," illustrated.

Correspondence

Endocrine Substances in Acne

Herman M Biggs Memorial Hospital
Ithaca

To the Editor

In the latest (September 1) issue of the JOURNAL you comment editorially on the use of estrogenic therapy in acne, with, I believe, the inference that the substance is a valuable aid in the treatment of acne. You refer to the work of Lawrence and Rosenthal, whose articles are suggestive and optimistic concerning the use of endocrine substances.

In the August 21 issue of the JAMA there appears an article by Williams and Nomland in which they review previous work and describe their own experiment. They mention the work of Lawrence and Rosenthal and the less optimistic reports of McCarthy and Hunter. They raise the point that previous findings are contradictory and opinion confused and variable concerning the use of gonadotropic substance in acne. They complain that too few controlled experiments have been made previously, and set about a controlled experiment of their own. Thirty-nine patients were used, half of whom received the endocrine produced by injection, the other half received injections of sterile water. The local treatment in all cases was identical. They conclude, "Our observations on thirty-nine students with acne, lead us to believe that a deficiency of the pituitary like hormone is not an important etiologic factor

in acne. The results show a slightly greater degree (7 per cent) of improvement in the acne of the group treated with gonadotropic substance from pregnancy urine compared with the control group. The difference is hardly sufficient, however, to justify the expense and effort of intramuscular administration of the gonadotropic preparation. It would seem that the local therapy is the most important factor in the management of acne."

A Doctor's Wife Speaks

To the Editor

The New York Physicians' Mutual Aid Association fills a special need in the life of the wives of physicians.

When, at an unexpected moment, the husband is cut off suddenly—his assets tied up, his unpaid bills outstanding, his estate requiring straightening out, his wife without ready cash—the Physicians' Mutual Aid Association steps into the gap by losing no time in paying to the widow her insurance benefit. This is a great boon to her.

Membership in the Physicians' Mutual Aid Association is more than an insurance protection. It serves a worthy cause and should be supported by all foresighted physicians for the sake of their wives and children.

MRS (Name Omitted upon request)

September 7, 1937

1938 Annual Meeting

Scientific Exhibits, New York City, May 9-12

Application blanks for Scientific Exhibits may be secured by medical colleges and hospitals in New York State by writing to the Chairman of the Committee on Scientific Exhibits, Dr William A. Krieger, 103 Hooker Ave., Poughkeepsie.

The plan this year is to have all these

exhibits furnished by hospitals and medical schools instead of by individuals.

Motion pictures will not be shown in the same room as the scientific exhibits at the Waldorf-Astoria Hotel, but in a special room of large size allocated for that purpose.

The first West Coast meeting of the American Academy of Orthopaedic Surgeons will be held on January 16-20, 1938, at the Hotel Biltmore, Los Angeles. Spe-

cial trains will be run with stop-overs at Santa Fe, the Grand Canyon, San Francisco, and other points. For information write to Robert L. Lewin, Hotel Biltmore.

- 3 30-4 00—"Reconstructive Tendon Surgery of the Hand" Dr David Goldblatt. (Amph B)
 4 00-4 30—"The Injured Joint" Dr Willis W Lasher (Amph. B)
 4 30-5 00—"Hernia." Dr Slattery (Amph B)

Urology

- 9 00-11 00—Operative Clinic. Dr Joseph A Hyams. (Room 6)
 11 00-1 00—*Clinical Presentations* (Room 5)
 1 Urethrocytographic and Cystometric Interpretations of Lower Urinary Tract Disorders Dr Herbert R. Kenyon.
 2 Urological Disorders in Children Dr C Travers Stepita
 3 Urographic Interpretations of Surgical Disorders of the Upper Urinary Tract Dr Stanley R. Woodruff
 4 Surgical Disorders of the Kidney Dr Clarence G Bandler
 5 Surgical Disorders of the Ureter Dr Joseph A. Hyams
 2 00-5 00—Cystoscopic Demonstrations, and Round Table Discussion of Urological Problems Dr Joseph A. Hyams and Staff (Rooms 5 and 6)

(Note New instruments and equipment, lantern slides, graphs and charts of the various operative procedures discussed will be continuously exhibited and demonstrated.)

Pathology and Bacteriology

- 8 00-8 30—Surgical Pathology Demonstration of the microscopic specimens from surgical operations of Friday, October 1 Dr Ward J MacNeal. Laboratory Lecture Room, 6th Floor
 8 30-9 00—Surgical Pathology Demonstration of the gross specimens from surgical operations of Monday, October 4 Dr S Milton Rabson. Pathological Laboratory, 7th Floor
 9 00-9 15—Serological tests for syphilis Dr Adele E Sheplar and Mrs Marguerite B Golar. Serological Laboratory, 6th Floor
 9 15-9 30—Agglutination tests for typhoid and for undulant fever Dr Adele E Sheplar and Miss Gladys Morton. Serological Laboratory, 6th Floor
 9 30-9 45—Streptococcus agglutination. Dr Adele E Sheplar and Mrs Margaret S Neil. Bacteriological Laboratory, 6th Floor
 9 45-10 00—Pneumococcus typing by Neufeld method. Dr Adele E Sheplar and Miss Gladys Morton. Bacteriological Laboratory, 6th Floor

10 00-11 00—Lecture demonstration on Experimental Therapy of local bacterial infections and of septicemias with aid of bacteriophages, immune serums, chemotherapeutic agents and transfusions Dr Ward J MacNeal, Dr Adele E. Sheplar, Miss Frances C Frisbee and Miss Martha Jane Spence. Laboratory Lecture Room, 6th Floor

11 00-11 15—Blood culture technic and demonstration of blood cultures Dr Adele E Sheplar and Miss Gladys Morton. Bacteriological Laboratory, 6th Floor

11 15-11 30—Blood sedimentation test Dr Adele E Sheplar and Mrs Margaret S Neil. Bacteriological Laboratory, 6th Floor

11 30-11 45—Experimental therapy of streptococcus infection in mice by sulphanilamide and γ serum Dr Adele E Sheplar and Miss Martha Jane Spence. Bacteriological Laboratory, 6th Floor

11 45-12 00—Apparatus and Technic of Fractional Transfusion Dr Ward J MacNeal, Mrs Margaret S Neil and Miss Anne Blevins. Bacteriophage Laboratory, 7th Floor

12 00-12 45—Technic of preparation of bacteriophages for therapeutic use. Miss Frances C Frisbee and Miss Marie Wasseen. Bacteriophage Laboratory, 7th Floor

2 00-2 30—Demonstration of pathological lesions of the eye in children Dr Louise H Meeker. Pathological Laboratory, 7th Floor

2 30-2 45—Demonstration of Mediastinal Tumors and of Congenital Defects of the Heart Dr Louise H Meeker. Pathological Laboratory, 7th Floor

2 45-3 00—Pathology of the tonsils, Metaplastic tumor of the colon, Carcinoid tumors Dr Louise H Meeker and Dr S Milton Rabson. Pathological Laboratory, 7th Floor

3 00-3 15—Unilateral fused kidney with purpura hemorrhagica, Carcinoma of ureter, Exstrophy of bladder, Leukoplakia of bladder Dr Louise H Meeker and Dr S Milton Rabson. Pathological Laboratory, 7th Floor

3 15-3 30—Erythroblastemia of infants Leukemia general and localized Multiple hemendotheloma. Dr Burr R Whiteher and Dr S Milton Rabson. Pathological Laboratory, 7th Floor

3 30-4 00—Pigmented tumors of the skin Dr D S D Jessup. Pathological Laboratory, 7th Floor

The Laboratories of this department will be open to members of the Medical Society throughout the entire day and the exhibits may be viewed at any time

Eighth District Branch

The program of the Eighth District Branch Annual Meeting, to be held at the Bartlett Country Club, Olean, October 7, is as follows

10 00 A.M. "The Use of Sulfanilamide in the Treatment of Infections" Francis P Schwentker, M.D., Director of Medical Research, City Health Department, Baltimore, Md. Sulfanilamide is indicated in the treatment of serious

infections with the beta hemolytic streptococcus. There is some evidence that it may also be helpful in the treatment of meningococcus and gonococcus infections as well as in pyelitis due to B coli or staphylococcus. The methods of treatment and the toxic manifestations of the drug will be discussed.

11 00 A.M. "Practical and Interesting Phases of Thoracic Surgery" Cameron Haight, M.D., University of Michigan, Ann Arbor, Michigan

with lantern slides Dr Rubin A. Gerber (Room 100)

2 00-3 00—"Diagnosis of Spastic and Flaccid Paraplegias" Dr James L. Joughin (Nerve Clinic)

3 00-5 00—"Technic of Lumbar Puncture, Cisternal Puncture, and Discussion of Treatment of Diagnosis and Neurosyphilis" Dr George S. Cattanaach (Nerve Clinic)

Ophthalmology

8 30-10 00—Refraction Clinic. Dr Isadore Givner

10 00-11 00—"Muscle Anomalies" Dr James W. White. (Eye Lecture Room)

11 00-12 00—"Pathological Conditions of the Eye," illustrated with microscopic slides Dr Louise H. Meeker (Eye Lecture Room)

12 00-1 00—"Headaches from an Ocular Viewpoint" Dr Rudolf Aebli (Eye Lecture Room)

2 30-3 30—"Fundus Lesions Pertaining to General Medical Diseases" Dr Martin Cohen (Eye Lecture Room)

3 30-5 00—Demonstration of Clinical Cases Dr Cohen and staff (Eye Clinic)

Orthopedic Surgery

(Program in Amphitheatre C until 5 P. M.)

9 00-10 00—"Chronic Arthritis" Dr Edward F. Hartung (Dept. of Medicine)

10 00-11 00—"Management and Prevention of Deformities in Arthritis" Dr John P. Stump

11 00-12 00—"Laboratory Aids in Diagnosis of Orthopedic Conditions" Dr Ward J. MacNeal (Dept. of Pathology and Bacteriology)

12 00-1 00—Lecture and Demonstration, "Plaster Technic." Dr John P. Stump

2 00-3 00—"Surgical Anatomy and Important Orthopedic Problems" Dr H. L. Wenger

3 00-4 00—"Consideration of Foot Problems for the Practitioner, Including Foot Strain, Weak Feet, Flat Feet, and Anterior Metatarsalgia" Dr Charles Ogilvy

4 00-5 00—Demonstration of Cases from Foot Clinic Dr Charles Ogilvy

5 00-6 00—Lecture and Demonstration, "Fascial Transplantation" Dr C. M. Gratz (Mortuary)

Otolaryngology

9 00-10 00—"Pathological Conditions of the Ear, Nose and Throat," illustrated with Microscopic slides Dr Louise H. Meeker (Dept. of Pathology and Bacteriology) (Sixth Floor Lecture Room)

10 00-11 00—Laryngeal Operations and Endoscopic Demonstrations Dr C. J. Imperatori (Morgue)

10 00-12 00—Nasal Plastic Operations Dr Gustave Aufricht. (Room 2)

11 00-1 00—Caldwell-Luc and Denker Antral Operations Frontal Sinus Operations Dr Charles M. Griffith. (Morgue)

2 00-3 00—"Indications for Simple Mastoidectomy and Some of the Complications" Dr James O. MacDonald. (Room 100)

3 00-4 00—"Endoscopy of the Esophagus and Upper Air Passages in Children" Dr C. J. Imperatori (Room 100)

Pediatrics

9 00-10 00—Ward Rounds in the Babies' Wards, for two groups of fifteen each Dr Marshall C. Pease and Dr Charles J. Leslie.

10 00-11 00—"Asthma and Allergy in Children" Dr Robert Chobot. (Children's Clinic)

11 00-12 00—Demonstration of Cases of Heart Diseases in Children Dr Martin M. Maliner (Children's Clinic)

12 00-1 00—Demonstration of Pediatric Cases Dr Adolph G. DeSanctis (Erdmann Auditorium)

2 00-3 00—"Preventive Pediatrics in Everyday Practice" Dr John Dorsey Craig (Children's Clinic)

3 00-4 30—Demonstrations of Common Infant Feeding Problems Dr Oliver L. Stringfield (Children's Clinic)

General Surgery

I OPERATIVE SCHEDULE

8 30-10 00—Dr Chas. Gordon Heyd. (Operating Amphitheatre)

8 30-10 00—Dr Edward C. Brenner (Room 4)

8 30-10 00—Dr Edward W. Peterson (Room 3)

10 30-12 30—Dr Thomas H. Russell (Room 4)

10 30-12 30—Dr Carl Eggers (Room 3)

2 30-4 00—Dr John F. Erdmann (Operating Amphitheatre)

2 00-3 00—Dr R. Franklin Carter (Room 3)

4 00-5 30—Dr J. William Hinton (Operating Amphitheatre)

II LECTURE SCHEDULE

9 00-10 00—"Administration of Anesthesia to Children." Dr T. Drysdale Buchanan (Amph. B)

9 00-10 00—Demonstration of Ulcer Cases Dr Jerome Selinger (Eye Lecture Room)

10 00-11 00—"The Surgical Indications of Thyroid Disease." Dr B. A. Goodman. (Room 100)

11 00-12 00—"Curiosities in Surgery" Dr John F. Erdmann (Erdmann Auditorium)

3 30-4 00—Motion Picture, "Diagnosis and Treatment of Gall-Bladder Disease." Dr R. Franklin Carter (Erdmann Auditorium)

5 00-5 45—Motion Picture, "Blood Transfusion—Unger Method" Dr Lester J. Unger (Erdmann Auditorium)

Traumatic Surgery

9 00-9 30—"The Infected Hand" Dr H. H. Ritter (Erdmann Auditorium)

9 30-10 00—"The Traumatic Shoulder" Dr H. V. Spaulding (Erdmann Auditorium)

10 00-10 30—Ward Round (for a group of twelve) Drs Ritter and Louis R. Slattery

10 30-12 30—Operations Dr John J. Moorhead (Operating Amphitheatre)

12 30-1 00—"Treatment of Acromioclavicular Separation" Dr Walter D. Ludlum. (Amph. B)

2 30-3 30—"The Fractured Hip" Drs Herbert M. Bergamini and Emmett A. Dooley (Amph. B)

Public Health News

Management of the Child with Rheumatic Heart Disease

There is no known successful remedy in rheumatic heart disease. Drugs are of value only in certain passing phases, treatment by vaccines or sera has proved disappointing, and dietary regulation is of less than major importance. Certain measures can be taken to place a child with this condition in as favorable an environment as possible for recovery, but if good fortune does not prevail, the physician must stand by and see his patient steadily decline. On the other hand, all advice as to care may be consistently ignored, and the child, seen perhaps after a lapse of a year or two, found to be in excellent condition.

Care of the child will involve not only therapeutic measures designed to alleviate his condition as one finds it, but also efforts to prevent further damaging incidents.

If the child is very ill when first seen, attention will probably center on the heart as a more or less isolated organ. Treatment directed to the heart itself will depend on the stage of the disease. In acute carditis, the physician must realize that he is dealing with inflamed tissue, and that drugs at present available cannot be expected to influence the inflammatory process. The cardiac muscle cannot be put at rest, but as close an approach as possible to this should be secured. The child should be comfortably settled in bed, hypnotics used if necessary to induce regular and restful sleep, and, in the presence of pain, morphine or other opium derivatives given freely. Too much emphasis cannot be placed on the necessity for rest and quiet as essential to a favorable outcome. Pressure from the child or his parents to shorten the rest period will tax the physician's patience, but he must meet this pressure understandingly, trying to avoid unnecessary fright to the family while remaining firm in his insistence on an adequate period of complete inactivity. A high caloric diet should be given, and regular elimination secured by means of some such mild laxative as mineral oil or agar. Salicylates are of value only if high fever and inflamed joints are present, and apparently do not affect the rheumatic process within the heart. Cardiac stimulants, such as brandy, strychnine, adrenalin or caffeine are to be avoided. Digitalis will be found ineffective

at this time. Heat, or sometimes ice, applied to the precordium, may be welcome.

One cannot say how long this acute phase may last, or whether the subsequent course will be toward recovery or toward a graver stage. Congestive failure may develop at this time or later in the course of the disease. Failure may be closely associated with the inflammatory process, or may seemingly be a result of myocardial exhaustion. Specific treatment can be applied to this condition, but we must bear in mind that the basic power of the heart itself to sustain its action is our most potent weapon. Orthopnea should be minimized by propping the child up in bed. It is desirable to limit fluid intake and if possible keep it below the urinary output. Digitalis should be tried and its effect observed. It should be discontinued at once if headache, nausea, vomiting or premature ventricular beats appear. Diuretics such as theocin, theobromine sodium salicylate, or salyrgan may be used. Saline cathartics are not advisable, since they are too disturbing to the patient. Intravenous injection of glucose, in solution of about twenty-five per cent, may be given two or three times daily and may prove of great benefit. In the presence of venous engorgement venesection may be done. This is not used as widely in practice among children as with adults. If a large pericardial effusion develops, paracentesis will be considered, although its value is doubtful. Large accumulations of fluid in the pleural or peritoneal cavities may also be removed by paracentesis.

The stage of chronic heart disease may be reached after either or both of the above stages, or it may develop insidiously, and be the type found when the child is first seen by the physician. These cases comprise a large part of practice among rheumatic fever patients, and are the ultimate test of the physician's skill in a very difficult field. They range, in degree of severity, from those who develop dyspnea on the slightest exertion and who must remain at rest in bed indefinitely, to those in whom the diagnosis of rheumatic heart disease is not even certain, and who are unrestricted or almost unrestricted in activity. Once the diagnosis of rheumatic heart disease is made with a fair degree of certainty, it is advisable to put the child to bed, if possible, for a period of ob-

Many diseases of the chest which were formerly considered rather hopeless are now being successfully treated by surgery. Most notable among these diseases are tuberculosis, bronchiectasis, carcinoma of the lung and constrictive disease of the heart. Furthermore, great progress has been made in the success of surgical treatment of abscess of the lung, chronic empyema, benign tumors of the chest, and many miscellaneous conditions. The subjects mentioned in this paragraph will be presented with lantern slides. Discussion by Henry Kenwell, M.D. and Leon J. Leahy, M.D.

12 00 M "Workings of Obstetrical Council in Erie County" Francis Goldsborough, M.D., Professor of Obstetrics, University of Buffalo. Dr. Goldsborough will review the work of the Survey Committee on Maternal Mortality in Erie County. The preliminary report on the work of this committee was presented at last year's annual meeting by Dr. Goldsborough.

Afternoon Session

2 00 P.M. Business meeting and election of officers

2 15 P.M. "The Private Practitioner and His

Cancer Patient" George W. Cottis, M.D. Campaign of public education. Are the laity being educated faster than the doctors? Some of the more common pre-cancerous and early cancer cases and the responsibility which they impose upon the practitioner. The tragedy of an educated patient and his ignorant or careless physician. Illustrative cases of breast and cervix lesions. Cancer phobia and the danger of unnecessary operations. Resume of accepted practice.

3 15 P.M. "The Surgical Complications of Acute Communicable Diseases" Francis J. Gustina, M.D. The paper is based upon the study of the conditions seen in more than ten thousand cases admitted consecutively to the communicable disease wards of the Buffalo City Hospital. All have been seen by the author. It will be noted that surgical conditions do occur not rarely in these diseases, and one should bear this fact in mind whenever the question arises. Such patients are not to be denied the benefits of early surgery even though their primary condition makes them more serious risks. Early recognition and prompt treatment are often followed by good results.

THE COUNTY SECRETARY

In the organization of medicine to promote the cause of medical science and the joint and indivisible interest of the physician and patient, the real base is the county secretary, says the *Wisconsin Medical Journal*. He collects the dues, not infrequently he arranges the program, he keeps the books and writes the minutes, he gives of his time to see those citizens who would have the county society consider this or that health program, and he orders the dinners and trusts that he has not ordered for more than will be present. All this we, as members, rather take for granted and indeed if a secretary is a good secretary, we proceed to re-elect him year after year, thus recognizing his worth and abilities.

Recognition through re-election is one

form. A more appreciated form is a prompt response of the membership to his occasional requests for aid. When he sends a return postcard to ascertain if we will be present—let us not forget to return it. When he calls for a payment of dues let us recognize his sacrifice of time by not requiring him to send us a second, third, and even fourth statement. When he asks that we aid in arranging the program, let us accept and do that much to help.

The county secretary gives generously and increasingly of his time in this day of perplexing problems that face medicine. We cannot compensate him by a salary, but at least we can recognize his service in little ways that perhaps will be even more appreciated.

A DOCTOR AND A LADY TOO!

In our parents' days, people had rather sour ideas regarding women in medicine, and the sourness is not all gone yet! How could she be a doctor and a lady too! We have proved ourselves ladies by knocking the stuffing out of that tradition. There are only about 7,000 of us in the United States—there should be more. We average good, bad and indifferent, prominent and obscure, relatively the same as men. There

is room for good doctors of both sexes—those with a medical conscience, but little room for any other kind. Most of our women doctors are holding responsible positions and practices to their credit and our pride. Women doctors have their peculiar problems, one of which is: To marry or not to marry—She will probably live to regret either state—*Lucy Stone Hertzog, M.D., Chardon, Ohio*

If the child remains at home throughout his illness, the family must be told of the nature of his disease and how best to care for him. Some families are gifted with the intelligence and ability to administer to their sick, others cannot with the utmost endeavor be taught to manage illness satisfactorily. It is apparent that if the home is not peaceful, or if care is not adequate, the child should be removed if possible. Since it appears that most children with rheumatic heart disease come from

poor families, social workers play a large part in the management of the rheumatic population of a community. Often they form a valuable bond between physician and patient. Little need be said of the importance of the physician, not only for his technical knowledge of the condition with which he is dealing, but for what he may bring, through a long disheartening period, of support and encouragement to the patient and his family.

—ROBERT SALINGER, M D, New Haven, Conn

Recent New York State Psittacosis Cases

Three cases of human psittacosis were reported in upstate July of this year. All three patients were members of one family.

The first person affected was an adult male who became sick on June 21. On July 4 the patient's wife was attacked, and on July 5 his daughter became ill. Illness in each case was characterized by persistent fever with nearly normal pulse and respiration rate, and by a severe unproductive cough without lung changes being observed on x-ray examination. White blood counts on the first patient were within normal limits.

Attempts were made to obtain sputum to examine for the presence of psittacosis virus, but it was not possible to secure satisfactory specimens. Diagnosis was made on clinical grounds and epidemiological considerations.

On investigation it was determined that the first patient raised birds as a hobby, and had an aviary of over 100 birds. This aviary included canaries, finches, white Java sparrows, cardinals, buntings, together with various types of parakeets and love birds. Until about July 1 when he entered

the hospital the patient had permitted no one else to care for these birds. Then, however, his wife and daughter assumed charge of the aviary and shortly thereafter were themselves attacked by psittacosis.

It was also learned that from one to two weeks before onset of symptoms in the bird fancier that various types of birds in his cages had begun to die of unexplained illness.

On August 10, seven parakeets, three love birds, and a canary were secured from the aviary in question. Gross visceral changes typical of avian psittacosis were found in one parakeet. The spleens of several of the other birds, including the canary, were enlarged. Psittacosis inclusion bodies were found within the cells of the last-mentioned parakeet. Mice were injected with material from each of these birds. Thus far, some of those inoculated from all three species have become sick and on autopsy psittacosis inclusion bodies have been demonstrated. As yet, the exact source of the infection among these birds is unknown, but the matter is under investigation.—*Health News*, September 13, 1937

Swimming Pool Manager Arrested for Violating Code

Nicholas Dyruff, manager of Seven Gables Corporation, owners and operators of Woodcliff Amusement Park near Poughkeepsie, was arrested on August 15 on a charge of operating a swimming pool in a park without a permit issued by the acting town health officer, Donald Malven, M D.

Dr Malven refused to issue the permit because of the existence of several violations of sanitary code regulations regarding the operation of swimming pools. As the result, Justice of the Peace Carlton B. Fitchette ordered the pool closed until a permit was issued. According to records of the State Department of Health, this is the first time that such action has been

taken by a local health officer to enforce provisions of the code.

The management decided not to open the pool again this season and further legal action was withheld.

One of the principal violations was the inadequate treatment of the water. Others include failure to maintain proper toilet facilities, failure to maintain sanitary bath houses or dressing rooms and failure to provide properly operated foot baths required for prevention of athlete's foot.

District Engineer J. E. Kirker, Jr., of the Poughkeepsie office assisted Dr Malven in making the inspection.—*Health News*, September 13, 1937

servation How long the child need remain in bed obviously cannot be stated dogmatically Pulse rate, respirations, temperature course, leucocyte counts, throat cultures, sedimentation rate, electrocardiograms, Roentgenograms, all may be used to contribute evidence and help to indicate the child's progress The judgment of the physician as to the condition of the child, however, must be the final court governing the duration of the rest period In any case return to activity should be gradual and the effect of each new privilege carefully observed It is often at the time that permission is first given to relax the stringent regulations keeping the child in bed that he gets quickly out of hand "A little activity" is a difficult thing to enforce Children are not easily taught to move deliberately, as are adults in tuberculosis sanatoria,—at the first loosening of the reins they tend to go into full activity with other children of their age Drugs play a minor role in the regime If cardiac damage is severe, digitalis will be given a thorough trial A tentative calculated dosage of 40 milligrams per kilogram of body weight may be used, but effective dosage is not so uniform as in adults Digitalization within forty-eight hours is desirable, thereafter keeping the child on a maintenance dose. Pulse rate in children may not be affected by digitalis The best guide to dosage is the electrocardiogram, using a P-R interval of 0.2 as an indication that digitalization has occurred, providing of course, that this interval was normal before digitalis was started

Small transfusions of blood, preferably from a donor convalescent from rheumatic fever, should be tried if the child's progress is not satisfactory This is a logical, though little used therapeutic measure Operative procedures, such as cardiac decompression should be considered if adhesive mediastinitis and pericarditis with cardiac compression are present, or when the heart reaches an excessive size Careful attention will be given to the diet, and the child offered a wide choice of foods at regular intervals The caloric intake of course will be watched, and all vitamins provided in some excess During the summer months exposure to sunlight seems of value, and a sun lamp or ultra-violet light may be used during the winter months As the child's strength increases, regular moderate exercise, under careful supervision, is desirable, but must be kept well within the child's functional capacity

In management of the long and often discouraging stage of chronic heart disease

the physician cannot fix his attention exclusively on the heart. He must not forget that he is dealing with a frightened, hurt child, and endeavor at every opportunity to keep up morale. He cannot, or should not leave the child in bed with only his own thoughts to occupy him Some occupation, such as reading, weaving, modeling, painting, should be allowed as soon as possible A possible early return to school for short sessions will often be found the most encouraging promise to offer After the child reaches a certain period in his convalescence it will be noted that his day is quieter if he is allowed to attend school for a limited time.

Let us suppose that the child's progress is satisfactory, and that after six months he is found to be vastly improved, what may be done to minimize the chance of reinfection and another damaging cardiac episode? "The Rheumatic child reacts rheumatically" He is reacting to something not specifically known at present. We are unable to influence his natural reactivity so we must consider the advisability of removing him from the environment where he has the chance to react. This may mean a home away from the family in which he has developed the disease. Convalescent homes, although totally inadequate in number, are available in some localities In general, children are found to do better in these places than in their own homes Better than this is removal of the child from the community where the disease is prevalent, to one, such as Florida or New Mexico, where apparently less rheumatic fever occurs It must be remembered that in any case, following a period of residence away from home, the child almost surely must return to his own family, to be exposed again, as he was originally, to some of the etiological agents of rheumatic fever

The question of the value of tonsillectomy in prevention of recurrences of rheumatic fever is controversial It should be emphasized that if this operation is deemed advisable, complete removal, by means of careful dissection, should be done

The value of early diagnosis may fail to be manifest in many cases in which the course of rheumatic heart disease is relentlessly downhill, but the patient's prognosis surely depends to some extent on early recognition of the disease and application of measures to combat it.

Besides the child himself, others who will probably be involved in his care are his family, a nurse or social worker, and his physician Cooperation between these is highly desirable.

Inter-State Postgraduate Medical Association

The International Assembly of the Inter-State Postgraduate Medical Association of North America, under the presidency of Dr John F Erdmann of New York City, will be held in the beautiful new public auditorium of St Louis, Mo, October 18-22, with pre-assembly clinics on October 16 and post-assembly clinics October 23 in the hospitals of St. Louis

The aim of the program committee, with Dr George Crile as chairman, is to provide for the medical profession of North America an intensive postgraduate course covering the various branches of medical science. The program has been carefully arranged to meet the demands of the gen-

eral practitioner, as well as the specialist. Extreme care has been given in the selection of the contributors and the subjects of their contributions.

The St. Louis Medical Society will be host to the Assembly and has arranged an excellent list of committees who will function throughout the Assembly.

A most hearty invitation is extended to all members of the profession who are in good standing in their State or Provincial Societies to be present. A registration fee of \$5 00 will admit each member to all the scientific and clinical sessions.

PNEUMONIA CONTROL PROGRAM

Post-Graduate Educational Institutes in Pneumonia for the General Practitioner

The New York State Medical Society in collaboration with the Bureau of Pneumonia Control of the New York State Department of Health and in cooperation with several of the large medical school hospitals of the State will present the following program at the one day Institutes on "The Diagnosis and Treatment of Pneumonia"

MORNING SESSION

- 9 00 Registration
- 9 30 Lecture—The Early Clinical Diagnosis of Pneumonia
- 10 00 Lecture—The Bacteriological Diagnosis of Pneumonia
- 10 30 Lecture demonstration—Oxygen Therapy of Pneumonia
- 11 15 Serum Treatment of Pneumococcus Pneumonia—guest speaker Discussion—based on New York State experience with Type I Serum—1936-37

AFTERNOON SESSION

- 2 00 Group demonstrations on serum treatment
 - 3 00 Clinic Course—complications—x-ray
 - 4 00 Individual conferences with speakers
- Sound moving pictures on serum therapy and nursing care. Outgoing registration

The speakers on the above programs will vary depending on the location of the Institute. The list of the guest speakers at the various Institutes follows

Syracuse	Dr J G M Bullowa
Rochester	Dr Rufus I Cole
Buffalo	Dr Russell Cecil
Albany	Dr Rufus I Cole
New York City	Drs Bullowa and Cecil

A schedule of the institutes with the counties served by each follows

Syracuse Institute, October 12

St Lawrence	Lewis	Onondaga	Broome
Herkimer	Jefferson	Cortland	Madison
Oneida	Oswego	Chenango	Cayuga

Rochester Institute, October 19

Wayne	Seneca	Ontario	Monroe
Tioga	Steuben	Chemung	Yates
Livingston	Schuyler	Tompkins	

Buffalo Institute, October 25

Orleans	Erie	Wyoming
Chautauqua	Cattaraugus	Niagara
Genesee		Alleghany

Albany Institute, November 9

Columbia	Albany	Warren
Schoharie	Saratoga	Hamilton
Schenectady	Washington	Franklin
Montgomery	Clinton	Otsego
Essex	Delaware	Fulton
Greene	Rensselaer	

New York City Institute, November 23

Suffolk	Nassau	Westchester
Rockland	Orange	Dutchess
Putnam	Ulster	Sullivan

Applications are to be sent to Dr Thomas P Farmer, Chairman of the Council Committee on Medical Education of the New York State Medical Society, 608 E. Genesee St., Syracuse.

Announcement of Pneumonia Case Report Award

The Advisory Committee on Pneumonia Control of the New York State Department of Health announces the award of

this prize of \$100.00, for the best report of a series of pneumonia cases, to Walter J Karwowski, M D, Johnson City

Dr Russell M Wilder of the Mayo Clinic, Rochester, Minn., will discuss "Pathogenesis and Etiology of Diabetes" at the next clinical session of the New York Diabetes Association of the New York Tuberculosis and Health Association. The session will be held at 8 30 p.m., October 15, in the Blumenthal Auditorium of Mount Sinai Hospital, 3 E. 99 St., New York

City. Louis I Dublin, Ph D, Third Vice-President and Statistician of the Metropolitan Life Insurance Company and Dr George Baehr will participate in the discussion.

Dr James Ralph Scott, Chairman of the New York Diabetes Association, will preside. The session is open to all physicians and medical students.

Medical News

Albany County

THE ALBANY COUNTY MEDICAL SOCIETY held its annual clam bake on Sept. 15 at Picard's Grove. The invitations were written in a humorous vein. Speaking of the sports program, the committee said "Between the time you arrive and the opening of the bake, if you still have your youthful vigor—and those of you who haven't but won't admit it—you may play baseball, barnyard golf and other innocuous games. Victims of arthritis will be given a suitable handicap (4-ounce bottle of arnica) but ordinary neuritis and the like gets no special consideration."

DR. JAMES E. McDONALD, of Cohoes, who died on Aug. 14, was Mayor of the city in 1920-21 and postmaster from 1922 to 1930. He practiced medicine there for thirty-seven years. His two sons are also physicians, Dr. William B. McDonald and Dr. James E. McDonald.

DR. FREDERIC CROUNSE, who died in Altamont on Aug. 9, practiced medicine there for thirty years and in Albany for ten years, retiring in 1929.

Erie County

VICTIMS OF HAY FEVER became subjects for tests by the Erie County Medical Society in September to determine the value of air-conditioning. The research was conducted in three air-conditioned rooms in the model home located in the Electric Building. Twelve persons were selected each day for the tests. The subjects spent about four hours in the rooms, while the scientists observed reactions to the air conditioning device, which removed about ninety-nine per cent of the pollen from the atmosphere through filtration. Working with the medical society on the project was the recently organized Air Conditioning Council of Western New York. Subjects for the experiments were chosen from persons recommended by the society.

Kings County

THE SECTION ON PHYSICAL THERAPY of the Medical Society of the County of Kings gave a series of three dramatized programs, illustrating some highlights in the development of physical medicine, over station WBBC, as follows: Sept. 13, "Sun-

shine from a Lamp," Sept. 20, "The Nerve of a Frog," Sept. 27, "Fever for Health." The programs were presented under the auspices of the Subcommittee on Radio Broadcasting of the Public Health Committee of the Medical Society of the County of Kings.

DR. JOSEPH SAMENFELD died in Germany, on Sept. 4. Dr. Samenfeld was a consulting physician on the staff of Lutheran Hospital, and on the visiting staffs of St. Catherine's, Mary Immaculate and Jewish Hospitals. During the World War Dr. Samenfeld had charge of gassed and wounded men returned for treatment. He received a medal from Congress. During the administration of former Mayor James J. Walker he was appointed chief of administration of Greenpoint Hospital.

Monroe County

A FLIPPANT WRITER for a Rochester newspaper reports that on Aug. 26

"The legal method of hitting a golf ball proved too expert for the men of medicine at Monroe Golf Club as members of the Rochester Bar Association took the measure of the Monroe County Medical Society golfers, 84½ to 50½."

"Led by barrister Calkins, who threw a 78 at the discomfited doctors, the lawyers ran away with the ball game. Best medical effort was contributed by Dr. G. B. Van Alstyne, who scored a creditable 80."

"Following the match, dark rumors spread among the doctors' forces to the effect that the lawyers had several ringers on their team, and court procedure was threatened at a later date."

"A huge turnout was on hand for the annual links collision."

New York County

THE TENTH ANNUAL GRADUATE FORT-NIGHT of the New York Academy of Medicine will be held November 1 to 12, with the sessions devoted to a consideration of "Medical and Surgical Disorders of the Urinary Tract."

DR. CHESTER TILTON STONE, 51, urologist at Bellevue Hospital, died at St. Luke's Hospital of heart disease on Aug. 27. He wrote for many medical reviews, and published several books, of which the best

known were "Blood Pressure" and "Dangerous Age"

DR EVERETT WILLOUGHBY GOULD, physician and trustee of Columbia University, died in August at the Forest Lake Club, Hawley, Pa. He was sixty-three. In addition to his general practice, he was consulting pediatric physician at St. Luke's Hospital.

Oswego County

THE MEDICAL SOCIETY OF THE COUNTY of Oswego asks the various Secretaries of other County Societies to post a notice in their Bulletins that the Oswego County Annual Meeting will be held October 14. The guest speaker will be Morris Fishbein, M.D., Editor of the *American Medical Association Journal*. His topic will be "Medicine and National Policies."

Dinner reservations can be made by writing the Secretary of the County Society, J. J. Brennan, M.D.

Queens County

THE EXECUTIVE BOARD OF THE Auxiliary of the Medical Society of the County of Queens met on Sept 7 under the presidency of Mrs. John W. Mahoney.

Rockland County

THE ANNUAL CLAMBAKE of the Rockland County Medical Society was held in "The Grove" at Summit Park Hospital with approximately seventy-five county and visiting physicians and their friends as well as county officials in attendance, on Sept 1.

Prior to the opening of the bake many of the guests took the opportunity to go through the newly finished hospital building which this time last year was only about half completed. The removal of the old building which it replaced and the stately appearance of the new structure came in for admiring comments by the guests as they were shown about by Architect Frederick Mellor, Superintendent W. W. Reynolds, and Dr. Ryan. The grounds have been attractively landscaped so that no trace of the old building now remains and a grass plot sweeps across toward the new red brick building set against a background of trees.

A PLUMBING CODE for Rockland County was declared a necessity by Dr. George Unsworth, Dr. William J. Ryan and Frank S. Barnes speaking to one hundred persons who attended the annual dinner of the

Master Plumbers Association at Villa Lafayette, Spring Valley, on Sept 3.

Dr. Unsworth, president of the Rockland County Medical Society and Suffern trustee, pointed out that investigation has decisively proved that water-borne diseases can in most cases be traced to faulty connection and drainage in plumbing systems.

"A modern water system is a monument of health to the community it serves," said Dr. Unsworth. "Plumbers should be required to know the simple laws of sanitation. Some plumbers violate sanitary rules, not through ignorance, but through greed and indifference."

Schoharie County

DR HERBERT R. BENTLEY, who died on Aug 26, was a past president of the Schoharie County Medical Society. He was sixty-five, and for thirty years was the only physician at Central Bridge.

Suffolk County

MISS MARY LIVERMORE, executive secretary of the Huntington Social Service League, was the guest speaker at a luncheon meeting of the Women's Auxiliary to the Suffolk County Medical Society on Aug 25, at Sayville. Miss Livermore spoke on "Hobbies for Handicapped Children," a project inaugurated by the auxiliary recently.

MRS. JOHN L. BAUER of Brooklyn, assisted by Mrs. Edwin C. Kolb of Holtsville, gave a benefit bridge for the Welfare Fund of the Women's Auxiliary to the Medical Society of the County of Suffolk, on Sept. 3.

Westchester County

THE WESTCHESTER COUNTY MEDICAL Society opened the 1937-38 season of Scientific Programs with a paper on the "Treatment of Acute Head Injury," given by Dr. Foster Kennedy at the regular meeting on September 21, at Grasslands Hospital. Dr. Kennedy is Professor of Clinical Neurology at Cornell University Medical College.

FINAL ACTION WILL BE TAKEN at the October meeting of the Westchester County Medical Society on the recommendation of the Comitia Minora that the annual dues be increased from \$15 to \$25 for senior members, and from \$7.50 to \$12.50 for juniors, effective in 1938. These dues are entirely separate from the State Society assessment of \$10 annually, which is paid through the County Society.

Hospital News

Accidents in Hospitals

THERE ARE "INNUMERABLE CHANCES for accidents" in the day's work in a hospital unless the service is skillful, conscientious, and careful, says a worker whose paper appears in *The Modern Hospital*. Hospital service is usually given under constant physical and mental strain, pressure, haste and tension, and any persons who are habitually careless or inattentive, or whose minds are on outside personal or social interests, or who are ignorant and irresponsible by nature or disposition, have no place there.

The patient himself may often cause the accident which injures him. He may be weak or faint, and fall easily, or may be using crutches, which he does not know how to manage. He may not be used to the narrow, high hospital beds with the new inner-spring mattresses, which are very resilient and buoyant, and may fall out of bed on the floor. If bed-sides are arranged to prevent this, the patient often resents having them and vigilant care is needed by the medical and nursing personnel, bed-sides of canvas or other material may be used, and personal restraints may be necessary.

Smoking in bed is another serious problem, remarks the author of this paper, Miss Anna D. Wolf, who presented it recently at a meeting of the Greater New York Safety Council. It is permitted more often now than ten or twenty-five years ago, and when efforts are made to control it, say, by limiting smoking to certain hours, the patient is apt to secrete his supplies of cigarettes and matches, smoke surreptitiously, and tuck away a lighted cigarette under his pillow when the nurse approaches. This is the kind of accident likely to happen at night, when fewer nurses are on duty and their visits are less frequent. A patient asleep on a smoldering pillow is an alarming sight not soon forgotten.

Some patients, of course, are mentally disturbed or delirious, and striking, biting, and hitting with nearby objects by patients are possible occurrences which the nurse must guard against. The removal of articles likely to be used for missiles and the

use of unbreakable materials and medical and nursing measures are usual precautions in the care of patients. Accidental burns do happen, despite all precautions, and despite the fact that they are considered a disgrace by the nursing staff. The use of heat in its various forms, dry or wet, or the use of chemicals, are usual causes. Electrical appliances are being used more and more in the hospital wards, and more and more vigilance is therefore needed.

Falls may be due to the condition of the floors, often highly polished, and the use of scatter rugs without nonskid pads. Objects misplaced, spilled water or solutions add to the hazards.

A hypodermic needle may be imperfect and snap off when injected, thermometer or glass irrigating nozzle may be cracked and break while in use, a caustic solution may be splashed near a patient, an examining table or wheel chair may tip if its supports are not secure. A constant check on equipment, prompt repair, supervision and careful performance of services are the best controls against accidents which lie largely in the hands of the nursing service.

Errors in medication which occur infrequently are guarded against by every possible means. Strict regulations in writing orders, detailed and errorproof techniques in carrying out the procedure, and complete attentiveness to the task at hand are the best safeguards against such mistakes. Special precautions, as coloring certain solutions, the use of particular kinds of receptacles for others, and the specific placement of highly potent drugs are used to promote safety. Many errors may be made by the confusion of patients, misreading the label, miscalculating or misinterpreting orders and trusting memory in pouring the drug. Contributory causes are generally haste, interruption, inattentiveness or concentration on other elements in the situation which distract a person from the immediate requirement. The chance of human error must be reckoned with.

Nine commandments for the prevention of accidents are listed thus

known were "Blood Pressure" and "Dangerous Age"

DR EVERETT WILLOUGHBY GOULD, physician and trustee of Columbia University, died in August at the Forest Lake Club, Hawley, Pa. He was sixty-three. In addition to his general practice, he was consulting pediatric physician at St. Luke's Hospital

Oswego County

THE MEDICAL SOCIETY OF THE COUNTY of Oswego asks the various Secretaries of other County Societies to post a notice in their Bulletins that the Oswego County Annual Meeting will be held October 14. The guest speaker will be Morris Fishbein, M.D., Editor of the *American Medical Association Journal*. His topic will be "Medicine and National Policies"

Dinner reservations can be made by writing the Secretary of the County Society, J. J. Brennan, M.D.

Queens County

THE EXECUTIVE BOARD OF THE Auxiliary of the Medical Society of the County of Queens met on Sept. 7 under the presidency of Mrs. John W. Mahoney

Rockland County

THE ANNUAL CLAMBAKE of the Rockland County Medical Society was held in "The Grove" at Summit Park Hospital with approximately seventy-five county and visiting physicians and their friends as well as county officials in attendance, on Sept. 1

Prior to the opening of the bake many of the guests took the opportunity to go through the newly finished hospital building which this time last year was only about half completed. The removal of the old building which it replaced and the stately appearance of the new structure came in for admiring comments by the guests as they were shown about by Architect Fredric Mellor, Superintendent W. W. Reynolds, and Dr. Ryan. The grounds have been attractively landscaped so that no trace of the old building now remains and a grass plot sweeps across toward the new red brick building set against a background of trees

A PLUMBING CODE FOR Rockland County was declared a necessity by Dr. George Unsworth, Dr. William J. Ryan and Frank S. Barnes speaking to one hundred persons who attended the annual dinner of the

Master Plumbers Association at Villa Lafayette, Spring Valley, on Sept. 3

Dr. Unsworth, president of the Rockland County Medical Society and Suffern trustee, pointed out that investigation has decisively proved that water-borne diseases can in most cases be traced to faulty connection and drainage in plumbing systems

"A modern water system is a monument of health to the community it serves," said Dr. Unsworth. "Plumbers should be required to know the simple laws of sanitation. Some plumbers violate sanitary rules, not through ignorance, but through greed and indifference"

Schoharie County

DR HERBERT R. BENTLEY, who died on Aug. 26, was a past president of the Schoharie County Medical Society. He was sixty-five, and for thirty years was the only physician at Central Bridge

Suffolk County

MISS MARY LIVERMORE, executive secretary of the Huntington Social Service League, was the guest speaker at a luncheon meeting of the Women's Auxiliary to the Suffolk County Medical Society on Aug. 25, at Sayville. Miss Livermore spoke on "Hobbies for Handicapped Children," a project inaugurated by the auxiliary recently

MRS. JOHN L. BAUER of Brooklyn, assisted by Mrs. Edwin C. Kolb of Holtsville, gave a benefit bridge for the Welfare Fund of the Women's Auxiliary to the Medical Society of the County of Suffolk, on Sept. 3

Westchester County

THE WESTCHESTER COUNTY MEDICAL SOCIETY opened the 1937-38 season of Scientific Programs with a paper on the "Treatment of Acute Head Injury," given by Dr. Foster Kennedy at the regular meeting on September 21, at Grasslands Hospital. Dr. Kennedy is Professor of Clinical Neurology at Cornell University Medical College

FINAL ACTION WILL BE TAKEN at the October meeting of the Westchester County Medical Society on the recommendation of the Comitia Minora that the annual dues be increased from \$15 to \$25 for senior members, and from \$7.50 to \$12.50 for juniors, effective in 1938. These dues are entirely separate from the State Society assessment of \$10 annually, which is paid through the County Society

about ready to "burst its walls." Architects were called in to make a preliminary study and in conference with the staff and others interested were informed that there was a definite need of expansion in every direction, practically all facilities appeared to be inadequate.

Fortunately, before further steps were taken, one member of the executive committee called for definite facts and statistical analyses for the past ten years. Figures on a truly comparative basis were available for a six year period. These showed that only the fifty-three adult ward beds

had been occupied to 97 per cent capacity during 1936. The conclusion was inevitable any general expansion was uncalled for, rather, there was merely a shortage of adult medical and surgical beds. A building program providing twenty-four such beds with a few other changes at a cost of \$75,000 took care of all needs instead of the original plan of constructing a new wing at a cost of about a quarter of a million dollars. The community was saved an unnecessary expenditure of \$175,000 plus interest on that sum for a period of at least five years, a total saving of say \$215,000.

Improvements

AS THE SITE FOR A NEW BUILDING to house its out-patient department the nine brownstone houses at 51 to 59 East 123 Street and 52 to 58 E. 124 Street, New York City, have been bought by the Hospital for Joint Diseases, which occupies the adjacent block-front in Madison Avenue, between East 123rd and 124th Streets, facing Mount Morris Park. The houses were bought for \$150,000 according to an announcement by Frederick Brown, president of the institution.

The houses, with three structures acquired previously, comprise a plot 151 by 100 feet in 123d Street and 72 by 100 feet in 124th Street. They will be razed and an L-shaped building erected on the site.

THE LENOX HILL HOSPITAL, in New York City, through a purchase just made of the building at 1080 Lexington Ave., has rounded out its ownership of the entire square block.

A new building, to be known as the Einhorn Memorial, is now nearing completion at 129 E. 76 Street. It will contain an auditorium, swimming pool and other appurtenances for hydrotherapeutic treatment.

WORK ON THE NEW FIVE-STORY ADDITION to the Buffalo General Hospital is going forward rapidly, and it is expected to be ready in the late fall. The addition is planned to enlarge and improve surgical facilities. Six new air-conditioned operating rooms will occupy the fifth floor. Former surgical rooms will be maintained, augmented with the latest in hospital equipment.

A SEVEN-STORY ADDITION to St. Clare's Hospital, New York City, is under construction on the adjoining vacant plot to the west of the present six-story structure. Excavation has been completed and the foundation started.

The entire building will be so arranged that air-conditioning may be had if desired. All private rooms will have baths, showers, and toilets. The most modern lighting and signal systems will be installed and all wards and semi-private rooms will be designed to insure maximum comfort. The structure is expected to be ready in about a year.

The main floor will have a large foyer leading to elevators, reception rooms, executive and business offices, record and staff rooms, doctors' library and conference room. The sisters' chapel will be preserved in its present location.

In the basement will be the receiving and accident rooms, morgue, pharmacy and nurses' quarters. The second, third, fourth and fifth floors will be devoted to private and semi-private rooms and wards. On the sixth floor will be the operating rooms. On the seventh floor will be a roof garden and four private rooms.

Other features of the structure include the installation of leadened chambers for x-ray treatments, special rooms for the application of radium molds and radon gas emanations, and operating rooms equipped with electro-surgical apparatus. The hospital is operated by the Third Order of the Sisters of St. Francis.

THE NEW YORK CITY DEPARTMENT OF HOSPITALS has filed plans for a \$10,000

1 Adequate numbers and discriminating selection of all personnel from the standpoint of personal and professional fitness

2 Detailed instruction of all personnel and patients

3 Meticulous and detailed workmanship

4 Constant and careful supervision of the service with constructive criticism

5 Elimination of those who evince repeated irresponsibility and carelessness

6 Careful selection, check up and repair on all equipment.

7 Complete and detailed investigation of all incidents which may result in injury to those involved

8 Remedial measures against subsequent recurrence.

9 Building up and establishing a consciousness on the part of every individual that safety is the criterion for all activities

Those Costly Empty Beds

IT IS A STARTLING FACT that on the average day the general hospitals of the country are carrying fifty or more empty beds for every hundred occupied. That is the statement of Mr Charles F Neergaard, Chairman of the Committee on Hospital Planning and Equipment of the American Hospital Association, in an article in the *Journal of the AMA*. This fact, moreover, he adds, has not been generally realized in medical and hospital circles, its significance in terms of money has not been understood.

"The most wasteful thing in a hospital," he declares, "is a bed that is never needed," and he cites a report of his committee which claims that a far smaller margin of empty beds would be better. Instead of three beds for every two patients, it is sufficient to have five for every four. On this basis the general hospitals in 1934 had 87,500 beds more than they required, an excess that "had cost the public in fixed charges \$61,250,000—a sum sufficient to have paid for the care of nearly a fifth of all the patients whom the hospitals had treated that year."

Idle beds, he points out, are a heavy charge on institutions already suffering from a crushing load of charity work. This is of particular importance in view of the clear indications that hospital construction is being resumed on an increasing scale. The *Modern Hospital* reports 578 building projects last year aggregating nearly \$100,000,000. From coast to coast medical staffs are urging the need for new hospitals or the expansion and modernization of old ones. Before the hospital field embarks on a new era of construction or reconstruction based on hazy or incomplete knowledge, an effort should be made to determine some method of appraisal that will indicate in any given situation or locality how many beds are actually needed to cover a reason-

able reserve for peak loads. Construction programs beyond that point are wasteful and unsound, a handicap to management and an inexcusable drain on the all too limited funds available for health and philanthropic purposes.

What is more, figures disclose that the occupancy statistics show peak loads on an average of 17.4 days, or less than five per cent of the year. Even more worthy of note is the fact that in half of the total the peak loads occurred on ten days or less. This would indicate that for at least 355 out of 365 days the excess or reserve beds are rarely if ever used.

The nation's investment in general hospitals, we read further, averages \$5,000 a bed, with annual fixed charges at \$700 (\$250 for interest, \$150 for depreciation and \$350 for "readiness to serve" cost). As previously mentioned, the American Hospital Association report found that more than 87,500 beds are being maintained in this country in excess of needs, representing frozen capital of over \$437,000,000 and annual fixed charges of \$61,250,000.

Over half a million beds are now being maintained in this country in nongovernment hospitals and, notwithstanding about 145,000 idle beds in 1935, new beds are being added at the rate of seventy-seven each day according to statistics for the year 1936 compiled by the Council of Medical Education and Hospitals of the American Medical Association. As Dr Haven Emerson has said, "It seems preposterous to continue such relative idleness as is represented by an average occupancy of but sixty to seventy per cent of hospital beds."

The recent experience of one hospital, as told by this authority, is interesting. During the latter part of 1936 it experienced a gratifying increase in occupancy and agitation was started for "a new wing." There was a general feeling that the hospital was

Malpractice—Judgment of Surgeon as to Methods

The highest Court of one of the Western States this year passed upon a malpractice case in which the principal question was the extent to which a surgeon is entitled to follow his best judgment as to choice of methods.* The decision favoring the doctor is one which merits space in these columns.

The plaintiff in the action was the husband of a patient who had died following an operation performed by the defendant, Dr. G. The claim was that the malpractice of Dr. G. had been the cause of the patient's death.

It appeared that the patient when in about the fifth month of pregnancy suffered from severe hemorrhages, and entered a county hospital where she came under the care of Dr. G. who was in general charge of the hospital as county physician. The same evening after an examination and consultation with another physician Dr. G. obtained the consent of the patient and her husband and performed a cesarean operation. The fetus was removed, together with her appendix and tubes which were found to be diseased. Following the operation peritonitis developed and within a week the patient died.

The plaintiff in his complaint against Dr. G. charged principally that the cesarean operation had been an improper method of procedure, and consequently had caused the death of his wife. The defendant in his answer denied all negligence and denied that the operation was the proximate cause of death.

Upon the trial which resulted in a judgment in favor of the plaintiff, the plaintiff produced several physicians as experts as did the defendant.

One of the plaintiff's medical witnesses Dr. A. had attended the patient from time to time for two months prior to her hospitalization. He had observed her hemorrhages and had advised her entry to a hospital for the purpose of the evacuation of the uterus. He testified that in his opinion a cesarean should not have been performed, but that it was a well-defined case of miscarriage. However, Dr. A. admitted while on the witness stand that he had never performed a cesarean operation him-

self having only assisted at several such operations, none of which were cases of placenta previa. He conceded that the doctor in attendance is better qualified to diagnose a case than a doctor not in attendance. He admitted that his opinion assumed there was no placenta previa present. He also stated that he did not criticize the defendant for removing the tubes and appendix, and that he did not know whether the patient would have died if they had not been removed.

Another physician, Dr. D. testifying for the plaintiff stated his opinion that cesarean section was not proper or approved practice. He admitted that he had reached that conclusion without knowing the contents of the hospital record. (He had never examined the patient.) Dr. D. also agreed that there was a difference of opinion among medical authorities as to the propriety of a cesarean operation at less than a full term pregnancy. He also conceded that the physician in charge is the best judge of a patient's condition, and that he in deciding whether to operate a given case had to rely on his own best judgment.

Three other physicians who had never seen the patient, appeared as expert witnesses for the plaintiff and condemned the procedure adopted by him, giving testimony similar to doctors A. and D. when cross-examined.

Dr. G. testifying in his own defense, established that he had an extensive experience in surgery and obstetrics, and that he had had previous cases of placenta previa. He described having, after consultation with Dr. B., concluded that the case was one of placenta previa, and having decided, following his best judgment, to operate by cesarean section. He stated that he removed the placenta and fetus and found the tubes diseased and full of pus, and the appendix ulcerated, which he removed. The entire procedure, it seems, required just less than an hour. Dr. G. further testified to having devoted every effort after the operation to safeguarding the life of his patient but to no avail. He testified that he had in all respects complied with the general and proper practice in similar localities in like cases.

Dr. B., the consultant, Dr. H., the anes-

alteration job on the Hospital for Contagious Diseases, Brooklyn

Fireproof material will be installed and many sections of the institution which heretofore have been regarded as obsolete will be modernized

A REQUEST FOR NEGOTIATIONS by which New York City would obtain from Fordham University land on which to erect a tuberculosis hospital has been referred to the Comptroller by the Board of Estimate

A SIX-STORY HEALTH CLINIC will be erected by the Department of Hospitals at First Avenue and East Twenty-fifth Street, New York City. It will occupy a plot 99 11 by 49 2 feet at the northwest corner and will cost \$275,000

GROUND HAS BEEN BROKEN for the new addition to the Jewish Sanitarium and Hospital for Chronic Diseases in Brooklyn

Newsy Notes

THE HOSPITAL FOR JOINT DISEASES, New York City, announces a vacancy in Residence in Hospital Administration, to begin Jan 1, for three years. The hospital provides full maintenance and \$600 the first year, \$900 the second, and \$1200 the third. The requirements are graduation from a grade A medical school, two years general internship in a hospital of 200 beds, satisfactory references on personal qualities, and a desire to make hospital administration a life work.

A NEW TYPE OF HOSPITAL SHEETING made from "Cavalite" rubber-coated silk has been developed in the laboratories of the du Pont Company. Extremely light and smooth, it has been designed to fit snugly to the mattress, and, when covered with the bed sheet, its presence cannot be felt by the patient. A series of tests, reproducing every condition of rigorous hospital usage, was arranged to gauge the properties of the material. These included baking for thirty-five days in a Geer oven, a twenty-four hour period in which five sterilization preparations were applied, a four-hour exposure to steam, twenty-four hours of alcohol immersion, and twenty-four hours of ether, perspiration and urine testing. The sheeting showed no change throughout the tests. The new "Cavalite" sheeting is completely waterproof.

IT WILL COST NEW YORK CITY half a million dollars annually if the status of hospital interns is changed from clinical apprentices working for experience and little money to city employees drawing \$1,000 a year plus board and lodging, Dr S S Goldwater, Commissioner of Hospitals,

warned the Board of Estimate recently.

In a report asked by the Mayor and the other members of the board, Dr Goldwater urged them to go slow lest they lend support to many other groups within the department which are anxious to win salary increases.

"I see no reasonable objection," he wrote, "to legitimate efforts of this kind. I am certain, however, that if the interns succeed in obtaining mandatory legislation in their favor other groups of employees in the department will follow suit."

"It is for the Board of Estimate to decide whether it desires to encourage this form of activity as a method of fixing the salaries of city employees. The conditions of employment for interns should, of course be reasonable, just and proper, but the same is true of every other group of department officials and employees."

Interns once served a year without remuneration but in 1936 they were granted \$15 monthly plus their lodging. Commissioner Goldwater pointed out that New York occupies middle ground between those which pay interns larger salaries and those which follow the traditional system.

The pay rises included in the Burke bill before the Board of Estimate would, if followed throughout the country, add \$6,000,000 to the nation's hospital bill, Dr Goldwater said.

DR ROBERT E PIUNKETT general superintendent of tuberculosis hospitals of the State Department of Health, has been invited by the California State Department of Health to make a survey of the tuberculosis program in the Los Angeles County Department of Health.

DR ROBERT E PIUNKETT general superintendent of tuberculosis hospitals of the State Department of Health, has been invited by the California State Department of Health to make a survey of the tuberculosis program in the Los Angeles County Department of Health

Across the Desk

A Worldwide Epidemic—of "Jitters"

THE PRESIDENT OF THE UNITED STATES remarked the other day in a press conference that the whole world is growing "jittery," and as we survey the flaming newspaper headlines over our morning bacon and eggs we must admit that he is some diagnostician. Just what the "jitters" are, medically speaking, is open to definition and any of our learned neuropathologists are at liberty to have a whack at it but it has been common talk for years that our civilization has reached a pitch where it is getting on everybody's nerves. We become "high-strung," excitable, "jittery."

Mr. Roosevelt is not the only one either to put his finger on this dangerous condition. Lord Harder, in a recent address to the Royal Institution of Great Britain, declared that war is "the greatest of all modern diseases, though it is primarily a disease of the mind and not of the body." That is the outbreak of war here and there are symptoms of mental upsets. Rages and bursts of fury in an individual denote disorder of the mind, then why not in a nation, which is only a collection of individuals? The British Medical Association at a recent meeting adopted a resolution asking the Health Organization of the League of Nations "to deal with the psychology of war on similar lines to the section now dealing with epidemiology."

It Takes Strange Forms

There it is War Mentality is a psychopathic disorder that may break out into a disastrous and destructive epidemic. It first appears as simple or common "jitters," and should be watched with great care. When the League measures get going, we may see alert and husky health officers quietly stalking the jingoistic "100 per cent patriots" and hurrying them off to quiet retreats where they can be calmed down and, as it were, de-jittered.

Another form of jitters, widely prevalent, takes the shape of panic, or dread of war. The British people believe that the next war will start, unheralded, in the middle of the night, with hundreds, or even thousands, of planes filling the skies over England and

raining bombs of poison gas, flame, and high explosive on every roof and its sleeping inhabitants. It may be next week, tomorrow, tonight. Gas masks have already been provided for practically the entire population, and drills in their use are held everywhere. Lawns are catcombed with gas-proof underground chambers, gas-proof baby-carriages are on sale, and everyone is in a state of tense nerves and trepidation. They have the jitters.

Russia, in turn, has a spy fever. Every good "comrade" is officially urged to spy on every other "comrade," to catch him in some unguarded word or act that seems unpatriotic, so he can be stood up against a wall and shot. Everybody feels that everybody else is "after" him. The newspapers in that wonderful land of comradeship tell of hundreds and hundreds who have faced firing squads or have simply disappeared—"liquidated" is the official word, or, as we might say, poured down the drain. The happiness of living in that utopia has been painted in rosy colors by some of our pinkish illuminati, but in this particular investigation, paving the way, so to speak, for the epidemiological experts of the League of Nations, we can only write the land of Stalin down as another region with jitters.

The two great Fascist nations of Europe ought to be lands of perfect mental calm and quiet, for we are told, by their critics, at any rate, that nobody is permitted to do any thinking of his own, so that one's mentality should be entirely free from the slightest disturbance. Everyone's thinking is done for him—a delightful arrangement. Yet even there we hear of "liquidations," disappearances, fear of spies, all clear symptoms of jitters.

Space is lacking to explore this important subject further. We can look forward perhaps to specialization in jitters by eminent neurologists, to the addition of Professors of Jitters to our medical college faculties, and to great international Jitters Congresses, with learned and profound papers on its various manifestations and complications. In that day it is to be hoped that this humble introduction to its proper study will not be forgotten.

thetist at the operation, and a number of other doctors were called as witnesses by the defendant, and all approved the methods he had followed. All agreed that the case described was one of placenta previa, and that in his judgment he was entitled to operate as he had. The said witnesses also showed that the defendant had not increased the danger of infection, and that it was very doubtful if the patient could have lived if any other procedure had been adopted.

From the judgment in favor of the plaintiff, the defendant, Dr. G. took an appeal to the highest Court in the State. That Court determined that the evidence entitled the defendant to a nonsuit and reversed the judgment. In so ruling the Court said in its opinion:

This is not a case indicating that the defendant was incompetent, or that he failed to exercise his best judgment, or that he went outside of the recognized field of practice. All professional witnesses testifying made it clear that the controlling element in every case, such as here presented, is the attending doctor's ability and the exercise of his personal judgment, that they were so controlled in their own practice. Before liability attached to defendant in this case, it must have been shown that he was unskillful or negligent, and that through a lack of his skill or care, the patient died. By the evidence, the contrary is either shown or not questioned. It is undisputed that defendant is and was an experienced physician and a skillful surgeon thoroughly familiar with cases of this nature, and apparently far more so, than anyone testifying either in his behalf or for the plaintiff. What was proper in the way of treatment or surgical procedure had to depend upon the condition found at the time of the operation of which complaint is made, and not upon a different condition said to have been present several hours before. Where the general consensus of

the opinion of all physicians testifying was to the effect that the physician or surgeon then in charge must be controlled by his best judgment, then it should not lie in the mouth of any witness to condemn the exercise of such judgment when exercised by an admitted skillful or experienced physician, and especially when each witness, testifying as an expert in such matters, reserved unto himself the right to exercise his own judgment in his cases and to proceed accordingly. The defendant did not undertake a wholly new experiment but, according to the evidence, followed a method that had been previously used with success by himself, and a procedure—admittedly rare—but known to have been sometimes used. As to the exact time when such an operation, as was here performed, is to be resorted to, it appears that the text writers are not fully in accord. Had defendant adopted a different course, it would have been contrary to his personal judgment, evidence of lack of professional knowledge in such matters, and he would have been guilty of not employing his best skill and care which ultimately was to be exercised in the case in hand. The first requirement in such matters is that the physician in attendance be competent in such matters, and, necessarily he must be careful. Nothing more can attend to meet urgent circumstances. He is not, and never can be, a warrantor of cures, or even favorable results. Intervening causes may sometimes thwart the highest skill employed in the accustomed or only procedure known.

This record presents a clear case in which the medical witnesses disagree, and in such circumstances the competent physician in charge is bound only to exercise his best skill and judgment in determining the course to be followed and acting accordingly. In so doing he incurs no liability. It is for him to accept and act upon one practice or the other, and not for a jury blindly to determine the course which should have been followed, by a verdict of liability.

When you come home as daylight dawns,
Who turns in bed, and only yawns?

The Doctor's Wife.

In broken bone or typhoid fever,
Who thinks you're tops like John B
Deaver? The Doctor's Wife.

When accounts run low and it's your crisis,
Who lets you down by easy lysis?

The Doctor's Wife

When you're so tired you could die,
Who lifts the 'phone and tells a lie?

The Doctor's Wife

'Less some one lies and screams with pain,
Then sends you out in snow or rain?

The Doctor's Wife.

If I am by you understood
Who takes care of the neighborhood?

The Doctor's Wife

VACANCY FOR MEDICAL OFFICER

The U S Civil Service Commission announces an open competitive examination for the position of associate medical officer at \$3,200 a year. Applications must be on file with the Commission at Washington not later than Oct 18. Forms may be had

from the Secretary, Board of U S Civil Service Examiners, at any first-class post-office, from the U S Civil Service Commission, Washington, D C or from the U S Civil Service District office, Federal Bldg, Christopher St., New York City

Books

Books for review should be sent to the Book Review Department at 1315 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

- Textbook of General Physiology.** By T. Cunliffe Barnes, D.Sc. Octavo of 554 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1937. Cloth, \$4.50.

REVIEWED

A Handbook of Hygiene for Students and Teachers. By Cyril G. Eastwood, M.B. Duodecimo of 358 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$2.50.

The author attempts to arrange a handbook on the essential knowledge of biology, anatomy, physiology, hygiene and first aid, written in non-technical style with illustrations and tables. It is a formidable

undertaking, and the writer has produced a reasonable satisfactory work for non-medical students taking an elementary course in physiology and hygiene. It treats of all major subjects, and contains a great deal of information, and though in some instances greatly condensed is readily grasped by the student, although the discussion must of necessity be limited, as all the topics are contained in 358 pages.

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

Watch that Camel

THE CAMEL THAT THRUST ITS NOSE into the Arab's warm tent, then its head, then its shoulders, and finally its whole body, had nothing on socialized medicine in the matter of stealthy pushfulness. It was only in June that a Washington dispatch reported the President as saying "that he has no legislation in mind for Federalized medicine as advocated before the American Medical Association by Senator J. Hamilton Lewis," but a few brief weeks later, on September 3, the New York newspapers ran headlines saying that "New Deal Plans to Seek Health Insurance Next." "A health insurance system," said the dispatch, "holds a high place on the Administration's calendar of legislation 'futures,' it was learned on good authority today."

The plan, it seems, is to have the health insurance bill introduced by Senator Robert F. Wagner, of this State, who was the sponsor of the Social Security Act. It may be introduced at the coming session, or held over till the next, but "advocates of the measure favor early introduction, because they expect that it will stir up such a bitter controversy that it may take two or three years to get the bill enacted." Their expectation is entirely correct. The delay "may be for years, or it may be forever." These pesky doctors seem to have a stubborn streak in them, like the old Continentals in their ragged regimentals, or the Greeks at Thermopylae, they don't know when they are licked.

A Nosey Gesture

The camel's nose also appeared, pushing its way, on September 1, when the government-aided Group Health Association clinic opened in the national capital. It is "the Roosevelt Administration's initial experiment in socialized medicine," reported the Washington correspondent of the International News Service. It is said to be financed by the Federal Home Loan Bank and aided by the Twentieth Century Fund of Edward A. Filene, of Boston. David Lawrence, in his syndicated dispatches, reports that the plan is to apply for the present to Washington employees of the Home Owners Loan Corporation and the Federal Home Loan Bank Board, "but it is so set up that it can just as readily be extended to all the 117,000 Federal employees here and

the 700,000 or more government employees throughout the country."

We are told to expect that this new move will be soft-pedaled in official quarters so as to hush opposition, and it will be compared to group health plans in private industry. But, adds Mr. Lawrence, "the new organization, nevertheless, is directly in line with what has been urged by persons inside the administration who see the job possibilities and patronage potentialities of a medical bureaucracy in the Government. The latest step, therefore, may be taken to mean that the campaign for 'socialized medicine' has begun."

Snarled up in the Ropes

Up in British Columbia the pushful dromedary appears to have got himself all snarled up in the ropes, and is likely to spend the winter out in the snow-drifts. Several things combined to trip up the animal. In the first place, the original plan provided medical care for indigents, to be financed by the government, but the legislators flatly refused to appropriate any money for them—the very ones who needed it most. The measure finally passed was so emasculated that when a questionnaire was sent to 635 members of the College of Physicians and Surgeons of British Columbia, it was answered by 625, of whom 612 disapproved the plan and only 13 favored it. It became evident at once that no medical scheme could make a go of it without the doctors, and the plan was abandoned.

So then the government announced a plebiscite, and submitted to the voters on July 1 what has been called the most confusing question ever placed before the British Columbia public. It was not for an endorsement of the scheme as announced, but an academic query: "Are you in favor of a comprehensive scheme of health insurance progressively applied?" Nearly 400,000 votes were cast in the election, but fewer than half of the voters even replied to the question. Of those who replied, 116,223 voted in the affirmative and 80,982 in the negative. Months have passed, and the government has not yet announced whether it will go ahead with its health insurance.

A current expression for the jitters is to "get the hump." Here we have another victim. The camel has his already.

Watch that Camel

THE CAMEL THAT THRUST ITS NOSE into the Arab's warm tent, then its head, then its shoulders, and finally its whole body, had nothing on socialized medicine in the matter of stealthy pushfulness. It was only in June that a Washington dispatch reported the President as saying "that he has no legislation in mind for Federalized medicine as advocated before the American Medical Association by Senator J. Hamilton Lewis," but a few brief weeks later, on September 3, the New York newspapers ran headlines saying that "New Deal Plans to Seek Health Insurance Next." "A health insurance system," said the dispatch, "holds a high place on the Administration's calendar of legislation 'futures,' it was learned on good authority today."

The plan, it seems, is to have the health insurance bill introduced by Senator Robert F. Wagner, of this State, who was the sponsor of the Social Security Act. It may be introduced at the coming session, or held over till the next, but "advocates of the measure favor early introduction, because they expect that it will stir up such a bitter controversy that it may take two or three years to get the bill enacted." Their expectation is entirely correct. The delay "may be for years, or it may be forever." These pesky doctors seem to have a stubborn streak in them, like the old Continentals in their ragged regimentals, or the Greeks at Thermopylae, they don't know when they are licked.

A Nosey Gesture

The camel's nose also appeared, pushing its way, on September 1, when the government-aided Group Health Association clinic opened in the national capital. It is "the Roosevelt Administration's initial experiment in socialized medicine," reported the Washington correspondent of the International News Service. It is said to be financed by the Federal Home Loan Bank and aided by the Twentieth Century Fund of Edward A. Filene, of Boston. David Lawrence, in his syndicated dispatches, reports that the plan is to apply to the present to Washington employes of the Home Owners Loan Corporation and the Federal Home Loan Bank Board, "but it is so set up that it can just as readily be extended to all the 117,000 Federal employees here and

the 700,000 or more government employees throughout the country."

We are told to expect that this new move will be soft-pedaled in official quarters so as to hush opposition, and it will be compared to group health plans in private industry. But, adds Mr. Lawrence, "the new organization, nevertheless, is directly in line with what has been urged by persons inside the administration who see the job possibilities and patronage potentialities of a medical bureaucracy in the Government. The latest step, therefore, may be taken to mean that the campaign for 'socialized medicine' has begun."

Snarled up in the Ropes

Up in British Columbia the pushful dromedary appears to have got himself all snarled up in the ropes and is likely to spend the winter out in the snow-drifts. Several things combined to trip up the animal. In the first place, the original plan provided medical care for indigents, to be financed by the government, but the legislators flatly refused to appropriate any money for them—the very ones who needed it most. The measure finally passed was so emasculated that when a questionnaire was sent to 635 members of the College of Physicians and Surgeons of British Columbia, it was answered by 625, of whom 612 disapproved the plan, and only 13 favored it. It became evident at once that no medical scheme could make a go of it without the doctors, and the plan was abandoned.

So then the government announced a plebiscite, and submitted to the voters on July 1 what has been called the most confusing question ever placed before the British Columbia public. It was not for an endorsement of the scheme as announced, but an academic querv: "Are you in favor of a comprehensive scheme of health insurance progressively applied?" Nearly 400,000 votes were cast in the election, but fewer than half of the voters even replied to the question. Of those who replied 116,223 voted in the affirmative and 89,982 in the negative. Months have passed, and the government has not yet announced whether it will go ahead with its health insurance.

A current expression for the jitters is to "get the hump." Here we have another victim. The camel has his ahead.

BOOKS

October 1, 1937]

is given with little critical discussion of their pathogenesis. For the purpose that it was intended, we suppose it is adequate, and can serve only as a guide for more detailed study. It can never replace for the student the bigger and more complete texts.

DAVID M. GRAYZEL

Operative Surgery By Alexander Miles, M.D. and D. P. D. Wilkie, M.D. Second edition. Octavo of 631 pages, illustrated. New York, Oxford University Press, 1936. Cloth, \$7.25.

This volume of 631 pages with 329 illustrations appears as the second edition. The first edition was published in 1933 and was called "Manual of Surgery." At that time it was reviewed by the writer. He has therefore had the privilege of comparing the two editions.

The text has been completely revised to its decided advantage. Many new illustrations have been included. Generally speaking only one operative procedure is described and this procedure is the one preferred by the coadjutor, of which there are seventeen. We think, without exception, all of these coadjutors are from Edinburgh. The work, therefore, is a cross section of the present day practice of surgery in that city.

It is intended primarily for undergraduates studying surgery, for recent graduates, and for house surgeons who need a ready reference for their daily surgical problems. It is also recommended for those surgeons seeking higher surgical diplomas.

MERRILL N. FOOTE

Internal Diseases of the Eye and Atlas of Ophthalmoscopy By Manuel U. Troncoso, M.D. Quarto of 530 pages, illustrated. Philadelphia, F. A. Davis Company, 1937. Cloth, \$15.00.

It would seem that the fruit of the economic depression has ripened in the leisure hours of that period, and has now been brought to the ophthalmological market in the form of a new literature. Among these recent volumes dealing with the eye, we find this unique work of Troncoso. *Unique* seems a fitting adjective, for the volume is quite different in plan from any which has appeared in the English language. It might have been titled "Ophthalmology for the Internist," for such it is, and in this capacity will fill a longfelt need.

There are available many works on medical ophthalmology, but they have always seemed to the reviewer not to be well adapted for direct application to internal medicine. Haab related the retinal picture and the microscopic picture in his Atlas, Gowers emphasized the neurological aspects of fundus studies, Knapp brought out general med-

ical aspects of ophthalmology, and Foster Moore laid stress on specific medical entities. Troncoso has combined all these in a system of medical ophthalmic diagnosis. He acquaints the reader with basic anatomy and physiology, and with equipment and technique before delving into the realm of detailed diagnosis. He shows how data is gathered, and outlines theories before he leads on to interpretation of findings.

To be sure, no reviewer can feel that any book is quite perfect unless he has written it himself, and so in this instance, we find that we cannot quite agree with the statement on page 113 where Troncoso begins a chapter by saying: "All defects in the visual field are the result of injuries to the nervous structures." We would rather have seen him refer to functional and organic disturbances, not only of the nervous mechanism, but also of the vascular structures and of the media as well.

In the chapter on papilledema, the reviewer would like to have seen outlined the fourteen or fifteen current theories to explain the mechanism of choked disk and a table of statistics, for instance those of Uthoff (p. 174). A selected bibliography would have been useful.

Troncoso's work is modern and thoroughly worthwhile for the bookshelves of every internist and ophthalmologist.

JOHN N. EVANS

The Physiological Basis of Medical Practice A University of Toronto Text in Applied Physiology. By Charles H. Best, M.D. & Norman B. Taylor, M.D. Octavo of 1684 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$10.00.

Knowledge of physiology is essential to proper care of patients, and this fact is kept in mind by the authors of this complete, accurate and concise treatise on the normal actions and functions of the body. This volume of nearly 1,700 pages is divided into eight sections, of seventy-three chapters. The various systems of the body are studied and presented in an instructive, attractive manner. Comment upon this work can be made only in an exhaustive article and can merely represent a superficial value of the work. This volume should be studied carefully and would require considerable time. It is a valuable addition to the literature.

HENRY M. MOSES

Physiology in Health and Disease By Carl J. Wiggers, M.D. Second edition thoroughly revised. Octavo of 1124 pages, illustrated. Philadelphia, Lea & Febiger, 1937. Cloth, \$9.00.

The new edition of this text of physiology represents an extensive revision of the previ-

of a rather small book, which also includes a vocabulary of technical terms as well as an index.

Some idea of the subject material covered may be understood from chapter headings

Biological and Physiological Foundations, Nutrition and Dietetics, Hygiene of Children, Diseases of Children, Hygiene of the School, Hygiene and Education. The subject has been presented from a physiological approach, and the text is written so as to explain the illustrations, which are plain, many of them are simple diagrams. The book is well written in a popular style and is interesting. It is along the style of English books intended as an aid in preparing for examinations. It aims to clarify for the ordinary person, many of the physiological phenomena.

Medical and dental inspection of school children has been given much space, and the lighting and ventilation of school rooms has not been neglected. Sound practical advice is given as to what to do in emergencies as well as to whom to send for the physician.

The book is useful for students of the intermediate schools and is recommended for the use of teachers as a guide in the instruction of students in elementary and intermediate schools.

CHARLES T GRAHAM-ROGERS

Health Questions Answered By W W Bauer, M D. Octavo of 368 pages. Indianapolis, Bobbs-Merrill Company, 1937. Cloth, \$2.00.

The question and answer column is always of interest, whether it be in the publications for the laity or in the medical journals, and it has been a method widely employed by frauds and charlatans in the field of medicine to exploit nostrums and treatment for which the public has paid dearly both in health as well as in money.

The medical profession is now combating the charlatans, impostors and faddists, through the means of popular literature. *Health Questions Answered*, by Dr Bauer, is a book in this field, written in popular style for the laity, free from technical terms, and with no attempt to suggest treatment. Information is given as to harmful ingredients in exploited pharmaceuticals or cosmetics, as well as the danger in advertised types of treatment. The causes of many diseases are explained, and aids in banishing grave anxiety as to the outcome.

The book is well printed and contains interesting information. The questions are grouped in chapters, and there is a full

index so that it is easy to find the subject you are interested in. The book is one that the physician can recommend for the home library.

CHARLES T GRAHAM-ROGERS

A Manual of Radiological Diagnosis for Students and General Practitioners. By Ivan C C Tchaperoff, M D. Quarto of 256 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$6.00.

An x-ray manual for teaching and one of value to the student has been a long felt want. This 256 page book contains 249 excellent illustrations, mostly x-rays presented as positives. They are unusually clear, well selected and demonstrate the more important examples of bone and soft tissue pathology.

A chapter is devoted to the general discussion of diseases of bones and joints, followed by one relating to bone pathology affecting specific portions of the skeletal system. Due space is given to the more important and well established x-ray criteria in general diagnosis. The more recent advances, such as excretory urography, encephalography, myelography, uterosalpingography, placenta previa demonstration are also touched upon.

The book is designed primarily for the general practitioner who will find many key radiographs to aid him in his x-ray interpretations. It is also an excellent book for the student to readily acquaint himself with normal and pathological x-ray reproductions. For those interested in the subject as a complement to clinical medicine, it is extremely valuable and should prove of considerable assistance to those who would acquaint themselves with the specialty.

MILTON G WASCH

Aids to Pathology By Harry Campbell, M D & Kenneth Campbell, M D. Seventh edition. 16mo of 263 pages, illustrated. London, Bailliere, Tindall & Cox, 1936. (William Wood & Company, Baltimore.) Cloth, \$1.50.

The number of editions through which this book has gone speaks for its popularity. It is in most respects merely an abbreviation of standard textbooks of pathology. Accounts of different conditions are brief and for the most part accurate. However, in many instances the discussions are much too inadequate. In a discussion of blood groups, only the Jansky classification is mentioned. The chapter on tumors is only a short outline of different neoplasms and not a critical discussion of the subject matter. The same thing is true for diseases of the various tracts of the body. In many instances merely an outline of the diseases and their etiology

CORONARY ARTERY THROMBOSIS

Mode of Death and Analysis of Fatal Cases

A M MASTER, M D, S DACK, M D and H L JAFFE, M D *New York City*
From the Pathologic and the Cardiographic Laboratories, Mount Sinai Hospital

During the past three years we have studied 300 cases of coronary artery thrombosis at the Mount Sinai Hospital. In this report we are presenting the clinical and pathological aspects of the fatal cases in this series. There were seventy-nine deaths of which fifty-six came to necropsy. From the clinical point of view we have attempted to determine the circumstances attending death and the factors leading to a fatal issue. The importance of age and sex, heart failure, shock, sudden death, and heart and respiratory rate have been evaluated. From postmortem examination, we have sought to learn whether death can occur in a first attack of coronary artery thrombosis, whether the left anterior descending artery is properly designated the "artery of thrombosis," and whether the apex is the most common site of infarct. To answer these questions we examined minutely the arteries occluded and the sites of infarction. The presence of sclerosis in the coronary arteries was correlated with arteriosclerosis generally. The size of the heart was determined. The importance of mural thrombosis in the frequency of embolic accidents soon became evident.

Age and Sex

The prognosis in coronary thrombosis was better in the younger age group the

mortality rate of patients under fifty years of age was only fifteen per cent as compared to thirty per cent in those over fifty (Table I). Sex also was an important factor; the immediate prognosis was definitely better in men than in women; the mortality rate in the latter being one and one-half times as great in all age groups.

Mode of Death

Our series comprises only cases admitted to the hospital and of these, one-half entered on the first day of the attack. We did not include cases in which death occurred immediately or soon after the onset, that is, patients who died before they could be transported to a hospital. Bedford¹ and also Decoursey² have emphasized the fact that sudden deaths are frequently caused by coronary thrombosis. It is our belief, however, that this group is an inconsiderable number among all those who die of coronary thrombosis.

The largest single cause of deaths was *severe heart failure* as we have already reported³ (Table II). One-third of our fatal cases fell into this group and in about half of these there were contributory factors, such as, diabetic acidosis, bronchopneumonia, cerebral complications, uremia, and mesenteric thrombosis. In three instances severe heart failure followed another acute occlusion. Thir-

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 25, 1937*

ous one. It consists of alterations of certain statements and the addition of much new matter whereby information is brought completely up to date. A further revision in arrangement of various topics renders it more adaptable to teaching or for a review by those who have already had a course in physiology.

As in the first edition, the author tends to stress the fundamental biophysical mechanisms of physiology rather than the chemical. Upon this basis he discusses the clinical manifestations of physiological phenomena, with the aim of producing not only a textbook for students but also a reference medium for graduates. In general, it may be said that the new edition represents a distinct improvement, presenting subject matter for those interested in *human physiology*.

G B RAY

Operative Surgery By J Shelton Horsley, M D and Isaac A Bigger, M D. Fourth edition, volumes 1 and 2. Quarto, of 1387 pages, illustrated. St Louis, C V Mosby Company, 1937. Cloth, \$15.00.

In this fourth edition Doctor Horsley has secured the assistance of Doctor Bigger as co-author and has expanded his *Operative Surgery* to a two volume work of 1387 pages. Miss Helen Lorraine has added 500 beautiful new illustrations.

There is a section on *Neurological Surgery* by Dr C C Coleman, a section on *Urology* by Dr A I Dodson, a section on *Orthopedic Surgery* by Dr Donald M Faulkner, and a section on *Plastic Surgery* by Dr John S Horsley, Jr, all of whom are associated with Dr Bigger at the Medical College of Virginia. Dr Guy S Horsley has also contributed to the chapter on *Proctology*.

The subjects have been handled with such uniform excellence that it is difficult to pick out any one for special comment. There are 76 chapters, each interesting and instructive. The chapters on *Plastic Surgery*, *Flaps and Grafts* by John S Horsley, Jr might be mentioned in more detail. They are clearly and concisely written and profusely illustrated by photographs and drawings. The 79 pages devoted to these subjects are exceedingly practical.

Dr Bigger has a lucid style that is easy to follow. Among other subjects he carefully covers the modern surgery of the lungs, esophagus and heart. The reviewer is pleased to see that Beck's operation for the development of a collateral blood supply to the heart is described.

The reviewer is frankly enthusiastic about this *Operative Surgery*. Every medical student and practicing surgeon should study it.

HENRY F GRAHAM

Surgical Pathology of the Thyroid Gland. By Arthur E Hertzler, M D. Octavo of 298 pages, illustrated. Philadelphia, J B Lippincott Company, 1936. Cloth, \$5.00.

This book is a complete account of pathological changes observed in various forms of thyroid disorders. The reported observations are based upon a large experience in the clinical study of patients with goiter before operation, and in a detailed study of the tissue removed at operation, both by gross and microscopic examination. A careful follow-up has indicated the ultimate results.

The book is abundantly illustrated with photographs of patients with various types of goiter, and with a high degree of photography applied to gross specimens and to microscopic sections. The author, in an attempt to correlate the clinical story with the pathological findings, has kept in mind that goiter is a long story, and the eventual pathological changes may be indicative of symptoms long past. He is an advocate of radical surgery for the diseased gland and apparently has little fear of postoperative hypothyroidism and myxedema. He stresses the fact that the value of the basal metabolic rate in estimating the toxicity of a given case has been grossly overestimated.

If one does not agree with all his conclusions, he can take little exception to the detailed observations and the clinical facts which the author has so carefully compiled. The book is recommended to all students of thyroid disorders, pathologists, medical clinicians, and particularly the thyroid surgeon.

EMIL GOETSCH

Cataract. Its Preventive and Medical Treatment, for Specialists, General Practitioners and Students. By A Edward Davis, M D. Octavo of 161 pages. Philadelphia, F A Davis Company, 1937. Cloth, \$3.00.

This work reviews certain of the theories as to the cause of cataract, the development of cataract, and the pathology of cataract. It supplies, for this reason, a convenient means for anyone not unfamiliar with cataract studies during the past few decades. The reviewer was unable to discover new data. Methods used in the study of cases did not seem to be as complete as those used, for instance, by Dr Kirby, in his elaborate studies. Dr Davis rates the slit lamp study as of rather secondary value compared to other means.

This little volume is certainly worthwhile from a philosophical point of view, but to the reviewer, draws conclusions from inadequate material. It must be realized that many able men feel that medical measures are justified, but, without doubt, it is very difficult to present acceptable material to support the idea that medical treatment can either cure or retard senile cataract.

ing artery should no longer be designated the "artery of thrombosis." Often several arteries were occluded simultaneously, a point emphasized by Saphir et al,⁴ and Sprague and Organ.¹⁰ Almost forty per cent of acute and eighty per cent of old thromboses involved more than one artery.

In thirteen hearts with only a single acute or old thrombosis it was possible to determine the *site of initial thrombosis*. In these, the left anterior descending artery was first thrombosed in six instances, the right coronary in four, and the left circumflex in three, but the posterior wall was infarcted more often than the anterior. We wish to emphasize once more that in only five of forty-two cases was a single thrombosis found at postmortem and that in each case exitus followed a complication usually attributable, however, to the thrombosis.

Coronary thrombosis produces infarction of the *left ventricle* regardless of the artery involved (Table V). As we have already shown^{8, 6} and as others have intimated,^{9, 11} the posterior basal surface is the one most often infarcted and somewhat less frequently, the anterior apical wall or a combination of anterior and posterior walls. The septum alone was infarcted six times but in half the cases infarction of the anterior or posterior wall of the left ventricle was associated with infarction of the adjacent portion of

the septum. The right ventricle was occasionally the site of infarction but only when there was infarction of the left ventricle or septum. There was no instance of isolated right ventricular infarction.

A not uncommon sequela of myocardial infarction was *aneurysm formation*.⁷ It was present in ten cases, eight times on the anterior surface of the left ventricle (thrombosis of left anterior descending artery) and twice on the posterior surface. It was usually found in severely sick patients with hypertension and heart failure.

Cardiac hypertrophy was found in thirty-eight of forty-nine hearts weighed. Our criterion of hypertrophy was a weight of 400 gms or more. A large heart was found in patients with previous hypertension, multiple thromboses, and heart failure.

In the fifty-six patients examined postmortem, eight presented no or only minimal *arteriosclerosis* in the aorta and its branches. The average age of this group

teen patients died with a combination of *severe heart failure* and *shock*. *Severe shock alone* accounted for only seven deaths. Fifteen deaths were due to *embolism* and included nine instances of pulmonary infarction, five of cerebral embolus, and one of mesenteric and renal embolus. A fifth group was of particular interest. In this there were nine cases of *sudden death*, that is, unexpected fatalities in patients who were progressing satisfactorily or whose condition was not severe enough to anticipate exitus at the time. The causes of sudden death were another acute thrombosis in three instances, pulmonary embolism in two, and cerebral accident, rupture of heart and status anginosus in one case each. One death was unexplained. Finally, a few deaths occurred from *extracardiac conditions*, such as bronchopneumonia, diabetic acidosis, uremia, and ruptured gall-bladder. It must be remembered that in this grouping of the cases under specific causes of death, we have attempted to single out the chief factor, although frequently several played a role.

The majority of deaths occurred between the third and fourteenth day following the attack (Table III). One-third took place between the third and tenth week and only one-sixth within the first two days. These facts hold true for all the causes of death enumerated above, except for shock which usually led to death in the first three days. Even sudden death may occur at any time during the hospital stay.

Although *heart failure* was the direct cause of death in one-third of the patients it was present in ninety per cent of the fatal cases. It appeared in but sixty-four per cent of the nonfatal cases. We may conclude then that its presence indicates a poor prognosis. The failure was usually advanced, consisting of combined left and right ventricular failure and was of equal frequency and severity in left and right coronary thrombosis and in anterior or posterior infarction.

Similarly, *shock* was present in eighty-two per cent of the fatal cases and was usually associated with varying degrees of heart failure. It occurred in only one-third of the nonfatal cases.

Two very simple clinical observations, *heart rate* and *respiratory rate*, proved of

great prognostic value.³ Thus, when the heart rate rose to 120 or more, the mortality was fifty per cent. On the other hand, only five per cent of patients with a rate between sixty and one hundred died. Similarly, when the respiratory rate was thirty or more per minute, the mortality rate was forty per cent but when the rate was twenty or less, only one patient died.

Analysis of Postmortem Material

Location of Thrombosis and Infarction

We have found, as did Saphir and his associates,⁴ that in pathological examination it is essential to scrutinize the coronary arteries by making frequent cross sections in their entire course if old thromboses are to be unearthed. In our series, forty-two of the fifty-six postmortem examinations were rechecked in this way and the effort was well repaid (Tables IV and V). Only five cases were finally proved to have died with *one thrombosis*, a finding that emphasizes the rarity of death in a first attack. Moritz and Beck⁵ and the present authors⁶ have already brought out this point. Indeed, the frequency of old occlusions was remarkable, many cases having three or four. One hundred and fifty occlusions both old and recent were found in our forty-two cases (Table IV). Many old occlusions discovered at postmortem had not been suspected during life. In fact, half the cases with a history of but one clinical attack presented at least one old thrombosis.

For many years the anterior descending branch of the left coronary artery has been considered the one most frequently involved in coronary artery thrombosis⁷ and consequently, the anterior surface of the left ventricle the common site of infarction. In forty-six fatal cases reported by Levine⁸ the left anterior descending was occluded thirty-nine times and the right coronary artery only twice. However, in our series the right coronary artery was occluded both by recent and old thrombi with equal frequency as the left anterior descending artery, and infarction of the posterior basal surface was definitely more common than that of the anterior wall. We agree with Barnes and Ball⁹ that the left anterior descend-

with the secondary rupture linear in type. In the other, both were jagged linear marks. In these three cases there seems to be an infiltration in the wall causing a swelling and these ruptures take place in this area, with resultant hemopericardium and death within ten minutes.

If we consider this percentage as holding elsewhere, at least six per cent of coronary thrombosis that survive the preliminary shock must rupture.

In one case of an old insane patient, the pneumonia antedated the coronary occlusion.

The cases in this series varied from thirty-one to ninety-one in age, and several followed surgical injuries such as a broken leg.

I am wondering if the reason why so much of our thromboses take place in the left descending branch is because of the opening into the Thebesian circulation which is near that spot. In one of our cases we found an opening there, communicating between the occluded coronary and the ventricle.

I would also like to call attention to the fact that in many of our cases the mural thrombosis inside the heart is larger than the involvement outside, or on the pericardial surface. Is it possible that nature ordinarily splints inside and does this account for the absence of pericardial rub in most of the cases? I remember a number of years ago seeing a couple of hearts in Thorndyke Laboratory in Boston that seemed to show a definite communication between the coronaries and what would now be considered as part of the Thebesian circulation. Is it possible that occlusions in this territory lead to an infiltration within the wall and hence permit rupture? And do we have three ways of repair, depending on whether the infiltration is placed on the pericardium, on the epicardium, or within the wall itself?

In only three of our cases was syphilis present, and I am unable to evaluate its importance as a causative factor, except to notice that these cases tended to be a little younger than the average.

A WOMAN TRIES TO TEACH THE DOCTORS

Helen Rowland, who writes a syndicated column entitled "The Marry-Go-Round," may not know much about medicine, but she apparently knows something about women. The advice which she offered recently about "What A Doctor Should Know" is passed on by *The Ohio State Medical Journal* for the benefit of the medical neophytes, at the same time warning them not to take too seriously Helen's impression that every physician has pockets filled with currency and drives twelve-cylinder limousines.

To quote from her column as it appeared in *The Ohio State Journal*:

The time has passed when all that a doctor had to know was medicine.

The most successful doctors, today, are those who know most about psychology—particularly the psychology of women. Because the average man never goes to see a doctor until he is practically dying, or at least until he is actually in pain. It is poor, weak, "suffering" women who fill the doctor's pockets and pay for his limousines and golf sticks.

The young physician who wants to be popular and have Persian rugs on his office floor should know that the most effective modern "bedside manner" is a bright, cheerful, flattering smile, followed by a look of deep concern and a head shake after taking the pulse beat. Every woman is bent on having high blood pressure now and then.

He should know almost without taking her temperature or looking into the whites of her

eyes, whether a woman needs a sedative, a stimulant, an operation, or only a little sympathy and personal attention.

He should know how to listen until a woman has gotten her last symptom out of her system, and how to "advise" her to go somewhere she's been dying to go—whether it's the Riviera, Honolulu or just Saratoga Springs during the races.

He should know at a glance whether she has a genuine attack of cardiac trouble—or only a case of acute hysteria because her husband is having blonde-trouble or her boy friend is slow in coming across with the "wilt thou" and the solitaire. Some men can keep a girl waiting until she becomes positively jittery!

He should learn early how to remove a woman's inferiority complex and revive her crushed vanity and how to "set" her fractured heart so that it will knit quickly and soon be in working condition.

Above all, he should be aware that a woman must emote now and then or something will snap inside of her! And on such occasions he should know when to soothe her, when to scold her, when to jolly her when to bully her and when to take her seriously—even though he may long to rush out and slam the door behind him!

Of course, a little knowledge of medicine is necessary even to a young and good-looking medico—but it is merely incidental. The diagnosis is the big thing! And if a young and struggling doctor wants to see his office packed with "suffering" women, he should mix at least nine parts psychology with one part materia medica.

was only forty-five years. Hence, it would appear that arteriosclerosis may occur in the coronary arteries before involving vessels elsewhere.

As we have seen, *embolic phenomena* in coronary artery thrombosis are common and usually arise from mural thrombi which follow myocardial infarction. The incidence of mural thrombosis has been reported⁷ as more than fifty per cent. In our series it was present in thirty per cent, occurring most frequently in the left ventricle, less often in the right auricle and ventricle. *Pulmonary embolism and infarction* occurred eleven times. In five instances this was associated with thrombi in the right auricle or ventricle, in the remaining six, the source was peripheral venous thrombosis in four, and heart failure in two. It is possible, even when mural thrombosis is present, that the source of the pulmonary infarction is peripheral. Emboli to the brain, kidney, spleen, and intestines were less common than to the lungs.

It has long been observed⁸ that the *lungs* are frequently affected in coronary artery thrombosis. In only seven per cent of the cases were they uninvolved at postmortem examination. The usual findings were congestion (85%), pulmonary edema (53%), hydrothorax (39%), bronchopneumonia (28%), and finally pulmonary infarction (20%). In most instances these complications had also been observed clinically.

Summary

The mortality rate in coronary thrombosis increased with age and was higher in women than in men.

Discussion

DR CARL S. BENSON, *Binghamton*—First, let me pay tribute to the sterling work that has been done under Drs. Master, Jaffe, and Dack. Any report which they put forth is always based on careful study and can be accepted as authoritative. Then let me pay tribute to my friend and teacher, Dr. Clayton Greene, to whom I owe my interest in cardiology, and who inspired me in my work on this subject.

These men are giving the experiences of the large medical centers—New York and Buffalo—while I can speak for the moderate size territory such as our Triple Cities. Dr. Hugh Gregory, Dr. Jack Love, and Dr.

The chief causes of death were severe heart failure, heart failure with shock, severe shock alone, embolism, "sudden death," and bronchopneumonia.

Death from all types of lesions occurred most frequently between the third and fourteenth days.

Death in a first attack was rare. There were usually multiple old occlusions.

The right coronary artery was as frequently occluded as the left anterior descending and the posterior surface of the left ventricle as frequently infarcted as the anterior surface.

Cardiac hypertrophy was almost universal.

Arteriosclerosis may be limited to the coronary arteries in the younger age groups.

Mural thrombosis was common and often resulted in embolic accidents. The lungs were practically always involved.

We wish to thank Miss Ethel deHaen and Miss Ruth Oppenheimer for their assistance in collecting the data for this paper.

Victor Bergstrom, our pathologists, have been most kind in letting me use all their cases and have followed them with me.

We have seen most of the conditions mentioned by the New York group, and in going over seventy-two autopsy cases of coronary thrombosis, I have been struck with the fact that five of our cases have ruptured. In the last three of these cases the rupture has been not at the apex, but up in the side of the left ventricle. It has not been single but there has been a secondary smaller rupture from one to two cm from the main rupture. Two of the main ruptures have been about two mm across and almost round.

multiple small and large ulcerations, which tend at times to become grouped, necrotic, and enlarged to form phagedenic ulcers. Their edges are usually well-defined, slightly undermined, and bleed readily from the soft necrotic base. Fuchs,² Solomon,³ and Thalman⁴ were able to demonstrate the gonococcus in these ulcers. Gougerot et al⁵ called special attention to the differential diagnosis of these ulcers, for very often confusion may exist and they may be mistaken for chancroids or chancres. Furthermore, even the local lymphatic glands may be involved. Mirabeau⁶ and Von Vajsen⁷ observed cases with involvement of the local lymph chain, enlarged glands, and abscess formation from which the organism was recovered.

Very common local autoinoculable and contagious lesions occurring in association with the discharge, are the condylomata acuminata. The favorite site for these is in the genital region, particularly on the moist intertriginous areas of the perineum, inguinal regions, and anus. They form as a rule, small filiform, papillary growths and larger fig-sized cock's-comb-like elevations, covered with an offensive purulent secretion. At times, these lesions may be confused with condylomata lata, manifestations of secondary syphilis. The treatment of these lesions is at times troublesome, and destruction by means of electrodesiccation, surgery or radiotherapy, may be necessary before they are eradicated.

From the local sites the gonococci may enter the blood stream to be transported to the skin where they produce generalized exanthemata. The generalized skin eruptions of gonorrheal infection are of serious import. They usually occur in patients who are septic and bedridden. Accompanying the cutaneous eruptions, there are usually symptoms simulating those of typhoid fever, such as malaise, headache, high temperature, chills, profuse sweating, general aches, a palpable spleen, and at times, pinkish macules of the abdominal skin. The general clinical picture may also suggest infectious endocarditis, as occurred in one of our cases. However, the most frequent systemic accompaniment is gonorrheal arthritis.

The first mention of generalized skin lesions in gonorrhea must be credited to

Selle.⁸ In his textbook, "Medicina Clinica," published in 1793, there is this passage: "I know it from my own experience that the pus from the gonorrheal-infected urethra is sucked into the body and may cause arthritic pains in the body and skin lesions." Unfortunately, he failed to give us a description of these skin lesions.

Buschke⁹ classified these lesions and thereby clarified their etiologic relationship. In 1880, Finger¹⁰ called attention to three cases of purpura rheumatica complicating gonorrheal urethritis. His cases showed purpuric lesions on and around the swollen, painful, inflamed joints. In 1893, Vidal¹¹ described a hyperkeratotic exanthematous form of skin eruption observed in gonococcal infections.

Arning and Meyer Delius¹² found only six cases of hyperkeratosis and 147 cases of arthritis among 4,300 gonorrheal cases. Of 550 females with gonorrhea, twelve complained of arthritis and none of skin exanthemata. Of fifty-two cases with hyperkeratosis, Buschke and Langler¹³ found only three in females, two of which were in small girls. For an unknown reason, females with gonorrheal infection are more immune to generalized skin involvement than are males.

Buschke's classification of the exanthematous skin eruptions in gonorrhea has been generally accepted and has helped a great deal to clarify this subject. He divided the skin lesions into four groups:

- 1 Erythematous eruptions, with or without vesicle formation

- 2 Urticarial erythema and erythema nodosum-like lesions

- 3 Hemorrhagic lesions, with or without bullous formations

- 4 The hyperkeratotic lesions

There may also occur in addition to these groups of lesions, a papulovesicular type, another of herpetiform nature and finally, pustular lesions.

The diagnosis of a specific gonorrheal erythema or urticaria offers great difficulties. This is especially true in the differential diagnosis when drugs have been used in the treatment of the urethritis. Many of the drugs given during the illness may cause an erythematous, scarlatiniform or morbilliform eruption.

CUTANEOUS ERUPTIONS IN GONORRHEA

OSCAR L. LEVIN, M D and SEYMOUR H. SILVERS, M D, *New York City*

Today, the subject of gonorrhea is of even more paramount interest than ever before, because of the strenuous campaign being waged by the professional and lay health authorities, in the attempt to stamp out venereal infections.

It was recognized centuries ago as a serious disease, and in the old testament there are references to the loathsome condition that may result from sexual intercourse. In the 15th Chapter of Leviticus, there are detailed descriptions of its clinical manifestations, and hygienic management, as well as of measures to be observed in the after care.

Although it was recognized as being an infectious condition, it was not until 1879 that Neisser isolated the gonococcus as the specific, causative micro-organism. Bumm (1885) demonstrated its infective virulence by inoculating man with a pure culture that he had succeeded in growing upon coagulated human serum.

In the various papers that have previously appeared and are still appearing, the fact that the germ produces the inflammation in the genital organs is emphasized, but little attention is called to the fact that the gonococcus is often the cause of systemic disease. The gonococcal infections of the skin are not common when compared with the wide prevalence of the condition in the genital organs, or with its occurrence in other tissues, notably the joints. However, as stressed in this paper, there are frequently manifestations of the infection in the skin itself, that may vary from relatively minor importance to grave and even fatal termination.

Although of low viability and of little resistance to outside influences, the gonococcus may lie dormant within the body for years, and may at any time produce local and metastatic inflammatory reactions.

It has been estimated that from five to ninety-five per cent of adult males suffer or have suffered from gonorrhea. Although it is more difficult to determine

the prevalence of the infection among adult females, yet it may be conservatively stated that five per cent of them are or have been infected. About three per cent of gonorrheal patients are known to develop arthritis, and probably a slightly higher percentage would include all the cases of systemic gonorrhea. No survey of the incidence of cutaneous manifestations has been reported.

The micro-organism may be present in the blood stream, and transmitted by means of the circulation in a manner similar to that which occurs in gonorrheal arthritis, to produce the generalized metastatic cutaneous lesions. It has also been suggested that some of the manifestations may be due to the liberation of a gonococcal toxin.

It is, therefore, evident that the cutaneous lesions observed in gonorrheal infections deserve special attention. They may be at times of little prognostic importance, but at others, they may suggest an ominous issue.

Two types of lesions are described.

First, the localized forms, in which single or multiple lesions occur, usually near the site of the infection, and resulting from the direct infection of the skin by the gonococci or by the irritating discharge. These are usually confined almost exclusively to the sites on and about the genitalia.

Second, there are generalized or exanthematous forms which result from systemic dissemination of the micro-organisms and their toxins to produce metastatic lesions.

The local lesions are readily recognized, and a proper diagnosis is made with little difficulty. The most commonly recognized clinical forms of localized cutaneous gonorrhea are folliculitis and abscess formations on the genitalia and lower regions of the abdomen and thighs, resulting from inoculation of the skin by the urethral discharge. Jesioneck,¹ in 1903, was able to isolate the organism from these lesions, and describe their clinical and causal relationship. Less common is the formation of single and

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 26, 1937

multiple small and large ulcerations, which tend at times to become grouped, necrotic, and enlarged to form phagedenic ulcers. Their edges are usually well-defined, slightly undermined, and bleed readily from the soft necrotic base. Fuchs,² Solomon,³ and Thalman⁴ were able to demonstrate the gonococcus in these ulcers. Gougerot et al⁵ called special attention to the differential diagnosis of these ulcers, for very often confusion may exist and they may be mistaken for chancroids or chancres. Furthermore, even the local lymphatic glands may be involved. Mirabeau⁶ and Von Vajsen⁷ observed cases with involvement of the local lymph chain, enlarged glands, and abscess formation from which the organism was recovered.

Very common local autoinoculable and contagious lesions occurring in association with the discharge, are the condylomata acuminata. The favorite site for these is in the genital region, particularly on the moist intertriginous areas of the perineum, inguinal regions, and anus. They form as a rule, small filiform, papillary growths and larger fig-sized cock's-comb-like elevations, covered with an offensive purulent secretion. At times, these lesions may be confused with condylomata lata, manifestations of secondary syphilis. The treatment of these lesions is at times troublesome, and destruction by means of electrodesiccation, surgery or radiotherapy, may be necessary before they are eradicated.

From the local sites the gonococci may enter the blood stream to be transported to the skin where they produce generalized exanthemata. The generalized skin eruptions of gonorrheal infection are of serious import. They usually occur in patients who are septic and bedridden. Accompanying the cutaneous eruptions, there are usually symptoms simulating those of typhoid fever, such as malaise, headache, high temperature, chills, profuse sweating, general aches, a palpable spleen, and at times, pinkish macules of the abdominal skin. The general clinical picture may also suggest infectious endocarditis, as occurred in one of our cases. However, the most frequent systemic accompaniment is gonorrheal arthritis.

The first mention of generalized skin lesions in gonorrhea must be credited to

Selle.⁸ In his textbook, "Medicina Clinica," published in 1793, there is this passage: "I know it from my own experience that the pus from the gonorrheal-infected urethra is sucked into the body and may cause arthritic pains in the body and skin lesions." Unfortunately, he failed to give us a description of these skin lesions.

Buschke⁹ classified these lesions and thereby clarified their etiologic relationship. In 1880, Finger¹⁰ called attention to three cases of purpura rheumatica complicating gonorrheal urethritis. His cases showed purpuric lesions on and around the swollen, painful, inflamed joints. In 1893, Vidal¹¹ described a hyperkeratotic exanthematous form of skin eruption observed in gonococcal infections.

Arning and Meyer Delius¹² found only six cases of hyperkeratosis and 147 cases of arthritis among 4,300 gonorrheal cases. Of 550 females with gonorrhea, twelve complained of arthritis and none of skin exanthemata. Of fifty-two cases with hyperkeratosis, Buschke and Langler¹³ found only three in females, two of which were in small girls. For an unknown reason, females with gonorrheal infection are more immune to generalized skin involvement than are males.

Buschke's classification of the exanthematous skin eruptions in gonorrhea has been generally accepted and has helped a great deal to clarify this subject. He divided the skin lesions into four groups:

- 1 Erythematous eruptions, with or without vesicle formation

- 2 Urticarial erythema and erythema nodosum-like lesions

- 3 Hemorrhagic lesions, with or without bullous formations

- 4 The hyperkeratotic lesions

There may also occur in addition to these groups of lesions, a papulovesicular type, another of herpetiform nature and finally, pustular lesions.

The diagnosis of a specific gonorrheal erythema or urticaria offers great difficulties. This is especially true in the differential diagnosis when drugs have been used in the treatment of the urethritis. Many of the drugs given during the illness may cause an erythematous, scarlatiniform or morbilliform eruption.

One would hesitate to make a positive diagnosis unless there are such positive evidences as those reported by Dorner,¹⁴ who isolated the organism from the blood in a case of gonorrheal sepsis with a roseola. Similar difficulties are also encountered in the identification of urticaria during a specific infection. Erythema nodosum-like lesions were reported by Herman,¹⁵ and purpura was described by Chevallier et al.¹⁶ Hemorrhagic and bullous eruptions were also described by Welander¹⁷ and Siegel.¹⁸ Welander reported the occurrence of bullous and hemorrhagic lesions, together with a positive blood culture. In his case a new crop of papules, vesicles, bullae, and hemorrhages, appeared with each rise in temperature. Siegel¹⁸ reported the case of a four day old child of infected parents, who showed bullous, hemorrhagic lesions and large erosions. He was able to isolate the gonococcus from the unruptured lesions. Lieber¹⁹ also described similar lesions in newborn infants.

Probably the most common of the generalized skin eruptions encountered in gonorrhea is the hyperkeratotic form. Vidal¹¹ first described it as a complication of gonorrhea, and later, Buschke⁹ gave a comprehensive review of the subject. The keratotic lesions usually appear together with arthritic complications. They appear, disappear, and recur, depending upon the intensity of the specific arthritis. The usual areas of predilection are the extremities especially about the joints. The keratotic eruption may appear as round or oval-shaped, heaped-up lesions, varying from pea to palm or even larger in size and showing a tendency to become confluent. The color of the lesions may be gray, yellow, or copper. The heaped-up conical character of the lesions suggests a crust overlying a purulent base, but as a rule, when it is removed a fairly dry floor with some debris is found. The nails of the hands and feet are invariably involved. They are dry, brittle, and heaped-up both distally and laterally by a subungual keratosis. The entire nail, finger, or toe may be covered by the characteristic crust. Not infrequently, the scrotal and penile areas may show the typical lesions.

Histologically, the epidermis shows the most characteristic changes. There is

marked hyperkeratosis and parakeratosis, with absence of the granular layer. In the corium, the following changes may be observed: widening of the papillary bodies, a cell infiltration consisting mainly of mononuclear leukocytes, fibroblasts and plasma cells and occasionally large numbers of polymorphonuclear leukocytes, dilation of the blood vessels, but no change in the elastic tissue. Intraepithelial abscesses are found containing debris, epithelial cells, and some polymorphonuclear cells.

The keratotic elements of the lesions rarely disclose the presence of the organism in culture or stained specimens, but more often, as demonstrated by Dainow²⁰ and others, the gonococci may be found in the intraepithelial vesicles. In Gager's²¹ case of keratoderma, the lesions began with vesicles and pustules and finally evolved the typical keratoses. Extracellular gram negative diplococci were demonstrated in the pus from lesions and urethra. Wadsok²² reported finding gonococci in the tissue from a papule in a case of keratoderma blenorrhagica. DuBois²³ also was able to isolate the specific germ from skin lesions.

The specificity of these lesions has been questioned by some writers. Lohe and Rosenfeld,²⁴ and Lojander²⁵ observed lesions, many of them resembling those of keratoderma blenorrhagica in cases without evidence of gonorrhea. Rostenberg and Silver²⁶ also questioned the specificity of the lesion.

Case Reports

We are reporting four cases with gonorrheal skin lesions observed in the wards of the medical services of general hospitals.

CASE 1 B. T., white, female, single, aged twenty, was admitted to the Medical Service of Dr. Rappaport of the Wyckoff Heights Hospital on November 16, 1936, complaining of fever and pain in the right foot and the lower quadrants of the abdomen. She admitted venereal exposure and gave a history of frequency of urination and nocturia. The past history was irrelevant, except for the fact that she had been treated for a mitral stenosis in another hospital.

The patient was extremely pale and acutely ill, with flaring of the alae nasi and moderate dyspnea. The abdomen was soft,

and no masses were felt. There was a slight swelling of the right foot, with moderate tenderness over the dorsum. A blowing diastolic murmur was heard over the precordium and a systolic murmur over the apex. The second pulmonic sound was accented. The Bartholin glands were swollen and the vaginal walls were edematous. There was no vaginal discharge. Digital manipulation of the cervix uteri caused pain but no adnexal disease could be discovered.

Laboratory examinations. On admission, the hemoglobin was 36.5 per cent and the red blood cell count was 1,440,000. Following a transfusion the hemoglobin was raised to fifty-two per cent Sahli, and the red blood cell count to 2,390,000. The white blood cell count varied from 13,200 to 15,400, and the differential blood cell count showed eighty-five to eighty-eight per cent polymorphonuclear cells. Smears taken from the cervix were repeatedly negative for gonococci. The complement-fixation test was four plus. Blood cultures on five occasions were negative. The urine showed a two plus albumin reaction and contained red blood cells.

Course. During her stay in the hospital, she ran a high temperature that was spiking in nature, rising as high as 106°F. The pulse rate was 100 to 140 per minute and the respiration rate fifteen to thirty-six per minute. On December 7, an x-ray revealed areas of bronchopneumonia involving the lower half of both lungs. On December 8, there appeared a generalized but sparse eruption of pin-head to lentil seed-sized bluish and violet-red, round macules, with slightly depressed centers. Most of the lesions were on the extremities, and there was one on the left conjunctiva. The patient died on December 9.

Postmortem finding. A smear from the ventricular side of the mitral valve examined with a Gram stain showed the presence of many intracellular and extracellular Gram negative diplococci. The spleen contained a large, fluctuating yellow area filled with fluid. The anatomical diagnosis was acute vegetative gonorrheal endocarditis, infection of the spleen, and bilateral bronchopneumonia.

CASE 2 G. S., white, female, married, aged twenty-six, was admitted on October 20, 1936, to the Medical Service of Dr. A. A. Epstein, at Beth Israel Hospital, complaining of precordial discomfort and palpitation of five days' duration. Three days before admission, she noticed four small "blisters" on the hands. At the same time, dyspnea and orthopnea set in. One day be-

fore admission, she noticed a pain in the shoulder which became worse with motion. After her admission to the hospital, pain also appeared in both wrists. The joints, however, had not been swollen and there was no history of rheumatic fever.

Physical examination revealed an acutely ill patient. There was marked pulsation in the neck and a thrill was palpable over the mitral area. There was evidence of mitral stenosis and insufficiency, and aortic insufficiency. The tip of the spleen was barely palpable. The liver was not palpable. There was no ascites. A vaginal examination revealed no discharge and no abnormalities. There was tenderness and pain on moving the left shoulder, the left elbow, and over the left metacarpal bones.

Cutaneous examination. The skin of the patient was examined one day after admission to the hospital, and on that day showed an eruption that was disseminated and most marked on the extremities. The eruption consisted of about one dozen sharply circumscribed, small hemorrhagic lesions up to the size of a small pea. These were purplish-red in color, maculopapular, and hemorrhagic. The older lesions were elevated and formed vesicles containing blood. The centers were slightly depressed, and showed a tendency to crusting. Lesions which appeared subsequently tended to involve the backs of the hands, the fingers, and the regions of the elbows. When first observed, the diagnosis was that of a septic purpura, and a note was made that such lesions had been previously observed in gonococcal septicemia, and also in meningococcal septicemia (Fig. 1). Subsequently lesions also appeared on the soles of the feet.

Laboratory findings. The x-ray examination of the chest revealed a slight, generalized enlargement of the heart, with accentuation of the auricular curve. The electrocardiographic examination revealed a P-R interval of 120 with changes suggesting myocardial involvement. There was a moderate congestion of both lungs, with acinous and exudative changes at the roots extending into the infraclavicular areas. There was thickening of the interlobar pleura between the right upper and middle lobes. X-ray examinations showed no involvement of the bones or joints. Frequent urine examinations showed the presence of occasional faint traces of albumin. Blood cultures examined were repeatedly negative for gonococci. The gonococcus complement fixation test was four plus and the Wassermann test was negative. An exam-

ination of the smear from the cervix showed the presence of gonococci.

Course While in the hospital, the patient showed gradual subsidence of the general symptoms including the disappearance of the painful joints and absorption of the lesions under hyperthermia treatment. Repeated examinations of smears from the urethra and cervix later showed the absence of gonococci. A bronchitis which had developed, gradually subsided, and her general condition improved. However, she

Fig 1 Characteristic hemorrhagic vesicle of palm in case 2, gonorrheal septicemia. Similar lesions occur in meningococcal septicemia.

was again re-admitted to the hospital on December 13, and again on January 1, 1937, with a diagnosis of bronchopneumonia and cardiac complications. No skin lesions appeared during these periods.

CASE 3 J. D., male, aged twenty-three, single, born in the United States, was admitted August 26, 1933 to the Mount Sinai Hospital Medical Service of Dr. B. S. Oppenheimer. On admission, he complained of fever, pain, and swelling of the dorsa of both feet, of five days' duration. For four weeks prior to admission, he had migrating pains in the extremities, and for months, he had a gonorrheal urethritis, which was supposed to have been "cured" three weeks before admission.

The patient was acutely ill. His heart was not enlarged but auscultation revealed

a systolic murmur at the apex. The genitals were normal. Gentle prostatic massage did not produce any secretion. Both feet were swollen and warm to the touch. They were tender and painful on motion. The skin showed scattered erythematous areas on the left wrist, left shoulder, neck and chest. On the day following admission to the hospital, the skin lesions became more numerous, and in several places, assumed a hemorrhagic vesicular or pustular character. The left conjunctiva showed a small hemorrhagic lesion. During the following days, the swelling on the dorsa of the feet became fluctuating. The blood pressure was 126 systolic, and 80 diastolic. The temperature was 104.2°F.

Laboratory examination The white blood cell count was 30,000 and the differential leukocyte count showed eighty-six per cent polynuclear. The sedimentation rate was thirty-six minutes. The hemoglobin was eighty-six per cent. The urine was negative. Fluid obtained by aspiration of the joints revealed smears and cultures that were negative for gonococci. Similarly, smears and cultures from the hemorrhagic vesiculopustular lesions on the skin were negative. A blood culture for gonococci was positive after five days' incubation. The gonorrhea complement fixation test was four plus.

Course During his stay in the hospital, the patient received six injections of typhoid vaccine, beginning with ten million and rapidly increased to two hundred million. Under this form of treatment and additional symptomatic medication, the patient gradually improved and was discharged on September 20.

CASE 4 J. O., white, male, aged twenty-seven, born in the United States, was seen in consultation with Dr. J. F. Connell for the diagnosis of a skin eruption. The history indicated that the patient had been treated for a gonorrheal urethritis for two months. One week prior to the consultation, the ankles became swollen and the patient complained of general malaise and weakness. A generalized eruption appeared, and gradually all the joints became stiff and motion became painful. The past history was irrelevant. The patient had lost about thirty pounds since the onset of the illness.

The patient was very emaciated, and unable to move in bed because of weakness. The temperature was 100°F. The pulse rate varied from eighty to one hundred per minute, and respiration rate was twenty. The heart, lungs, and abdomen were normal. The joints of the knees, wrists,

ankles, elbows, fingers, and toes were moderately swollen and painful on motion

Cutaneous examination The skin was dry and showed a generalized eruption of crusted papules and plaques which were most marked on and about the joints. Some of the individual papules were pinhead in size, most intensely red at the base and paling toward the somewhat pointed top. Other lesions consisted of larger papules, forming confluent plaques covered with heaped-up crusts, resembling layer cakes. The uppermost layers of the crusts were grayish and brownish-red in color and easily detached leaving dry surfaces. The nails were colorless, thickened, and undermined by crusts and papules, which were abundant along the nail folds.

Laboratory findings The urine showed one plus albumin, but was otherwise negative. The red blood cell count was 3,500,000, and the white blood cell count 8,200. The blood smears showed seventy-seven per cent polynuclear cells, three per cent eosinophiles, and twenty per cent small lymphocytes. The hemoglobin was sixty per cent, Sahli method. The blood culture was negative. The Wassermann test was negative. The diagnoses were keratoderma blenorrhagica and arthritis of gonorrheal origin (Fig 2)

Discussion and Comment

The interesting, but infrequent gonorrheal complications of the skin discussed in this paper, have stimulated comment from numerous observers. The types of skin lesions that have been described, may be classified into two main groups (1) The localized forms that occur usually in the neighborhood of the primary focus of infection and result from direct infection of the skin by the gonococci, or as a result of irritation by the secretions, and secondary infections by alien bacteria, (2) the generalized forms, probably metastatic, and caused by the transport of the gonococci by the blood stream to the skin where eruptions result from the action of the micro-organisms and their toxins.

The localized skin complications of gonorrhea may easily be explained. However, more corroborative evidence is usually needed to involve the gonococcus in the generalized forms. It is still difficult to positively correlate the macular, papular, and urticarial eruptions with the gonococci in suspected cases. The ex-

anthematous types proved to be the most intriguing to the commentators. Unless very definite evidence is presented, such as the finding of the organisms in the lesions, or the presence of a positive blood culture, or a positive blood complement fixation test, it is still very difficult to make a positive diagnosis of these lesions. In addition, one must always bear in mind the possibility of dermatitis medicamentosa as it is frequently necessary to exclude drug ingestion or injection.

The specificity of the keratodermic type of the blenorrhagic eruption has fre-

Fig 2 Keratoderma blenorrhagica. Discrete keratotic papules and patches, involvement of the toes with destruction of nails

quently been questioned by some writers. Because of the similarity of this eruption to certain clinical forms of psoriasis, it would be difficult to deny that a superficial resemblance exists among keratoderma blenorrhagica, psoriasis arthropathica, and pustular psoriasis. The definite clinical course of keratoderma blenorrhagica as shown in our case rules out any suggestion of psoriasis. In our patient, there was no history of psoriasis before the onset of the illness, nor was there any familial history of psoriasis. The patient had a gonococcal urethritis which was followed by joint involvement and skin complications. The heaped-up character of the lesions, which suggested crusts rather than the scales of psoriasis and the acute nature of the illness, all pointed to gonococcal infection. We were not as fortunate as some other observers in obtaining a positive blood culture or in recovering organisms from the lesions.

A very interesting form of skin eruption and one which portends an ominous prognosis, is the hemorrhagic form. These lesions, when considered with other clinical facts, suggest gonococcal septicemia.

ination of the smear from the cervix showed the presence of gonococci

Course While in the hospital, the patient showed gradual subsidence of the general symptoms including the disappearance of the painful joints and absorption of the lesions under hyperthermia treatment. Repeated examinations of smears from the urethra and cervix later showed the absence of gonococci. A bronchitis which had developed, gradually subsided, and her general condition improved. THE HARVEST OF FOLLY

At the time when Bismarck seized upon medical care for an agency through which to control the masses of Germany, the medical profession of his land was making extraordinary strides of progress, both in the advancement of the sciences and in the application of them to the care of the sick. The momentum of its intellectual power carried Germany to a position of universally acclaimed world leadership in Medicine.

Such was the distinction held by Germany at the end of the nineteenth and beginning of the twentieth century. Compulsory health insurance brought the blight of

subordination of the profession to political control, regimentation and bureaucratic regulation. So were the economic foundations of medical care undermined. Progress lagged, then stopped. Germany has surrendered her place of leadership. Today in Germany the medical profession is pauperized, demoralized, stunned and devitalized. Where two decades ago a galaxy of brilliant medical minds shed an ever increasing light of knowledge we observe today a darkened horizon. Only a few faint stars survive. The profession could not live in poverty and retain its old vitality and vigor.—Dr Frederic E Elliott

SHIFT IN MENTAL HYGIENE POST

Resignation of Dr Frederick W Parsons as Commissioner of Mental Hygiene and appointment of Dr William J Tiffany, superintendent of Pilgrim State Hospital, Brentwood, L. I., to succeed him, were announced on Aug 26 by Governor Lehman. Dr Parsons, a native of Buffalo, has been in the state service thirty-five years having received his first appointment in 1902 as clinical assistant at the Hudson River State Hospital. He was appointed Commissioner of Mental Hygiene by former Governor Alfred E. Smith in January, 1927, and was reappointed successively by former Governor Franklin D. Roosevelt and Governor Lehman. His resignation became effective October 1.

He intends to make his home in New York City. Dr Tiffany, who is fifty-five, was graduated from the College of Physicians and Surgeons, Columbia University, in 1905. He entered the State Hospital service in 1906, after completing his internship at St. Joseph's Hospital, Paterson, N. J. He served in successive grades at Binghamton State Hospital, Manhattan State Hospital, and Kings Park State Hospital, of which he became superintendent in October, 1926. He was made superintendent of Pilgrim State Hospital in November, 1931, having been assigned there because of his organizing ability.

It is our opinion that the important clinical data to be taken into consideration are the history of a local gonococcal infection, the spiking temperature curve, the progressive anemia, the leukocyte count, the gonococcus complement fixation test, a positive blood culture, and the localized areas of purpura indicating embolic phenomena. In our three cases showing this type of lesion, to which Finger¹⁰ first called attention in 1880, we were able to obtain a positive blood culture in but one. One case showed unmistakable evidence of gonococcal septicemia at postmortem examination, yet repeated blood cultures had been sterile.

The tell-tale round or oval petechial and macular lesions usually do not appear in profuse crops. A dozen or less new lesions may appear with each new crop, and are usually accompanied by a sudden rise in the temperature. The areas most frequently involved are the skin over the extremities, especially in the region of the joints. The conjunctivae and the buccal mucosae are also occasionally affected. No part of the body is immune. The clinical evolution of the lesions is easily followed from the time when they first appear as red-blue macules to the later stages, when they evolve as elevated purplish, slightly umbilicated hemorrhagic vesiculo-pustules, with a grayish-brown color. Since the lesions appear in crops, one may at times observe numerous macules and vesicles of various colors in progressive stages. Recently Cohn,²⁷ Stone,²⁸ White,²⁹ Peters,³⁰ Kirkland,³¹ and Hoffman and Taggart³² reported cases of gonococcal septicemia and called attention to these purpuric lesions. Sometimes, these cases run a protracted course, may be followed for months by periods of apparent improvement alternating with exacerbations of symptoms and finally ending in death. As reported by Welander,¹⁷ the lesions may appear at any time. They may appear early in the disease, as in our second case, or just before exitus, as in our first case and in those reported by Cohn²⁷ and others. The case of Hoffman and Taggart³² showed some lesions twenty-six days before death and four days before death showed a positive blood culture. Two or three days before death, numerous crops of lesions had appeared over the body.

Unless these lesions are kept in mind by the clinician in suspected cases of gonococcal septicemia, they may easily be overlooked. At times, less than half a dozen may be present, and in rare instances because of the lack of a bright red color and the presence of a brownish tinge, they may be confused with lentigo Thayer,³³ who summarized twenty-two cases of cardiac complications of gonorrhea, found these lesions present in six of the eleven white and one of the eleven colored patients. He felt, however, that had these patients been more closely examined, and the search continued, all of them would have shown these lesions.

Summary and Conclusions

1 This paper presents a summary of the literature on the skin complications of Neisserian infection.

2 The skin lesions may be localized or generalized, few or numerous, and may appear in crops.

3 The regional lesions are produced by localized infection with the gonococci or discharge and present no evidence of systemic involvement. They are, as a rule, easily diagnosed, and respond to local therapy.

4 The generalized skin eruptions in gonorrhea constitute an ominous portent of serious systemic disease.

5 The gonococcal macular, papular and urticarial types should be differentiated from similar lesions due to concomitant use of drugs.

6 Keratoderma blennorrhagica may be distinguished from arthropathic psoriasis and pustular psoriasis by the history, symptoms, cutaneous manifestations, blood picture, histopathology, and clinical course.

7 In this paper, particular emphasis is placed on the occurrence of a fairly characteristic type of hemorrhagic lesion. It is our belief that it is caused by the invasion of the skin by the gonococci with the development of embolic phenomena.

8 In only one other infectious condition has one of us (L.) observed this characteristic lesion and that was in a case of meningococcus septicemia. The meningococci were subsequently isolated from the skin lesions.

study of thirty-nine different clinical conditions Fahraeus³¹ noted a parallelism between the amount of serum globulin or fibrinogen, and the sinking velocity of the blood cells. Many other observations have been made in this connection, it being almost axiomatic that a definite increase in fibrinogen and seroglobulin accelerates the rate of sedimentation. Goldberger³⁴ holds that failure of the plasma proteins to undergo change in uncomplicated acute appendicitis accounts for the unusual and valuable diagnostic phenomenon of a normal sedimentation rate in early acute appendicitis.¹⁹

An increase in the lipid content of the blood, particularly of cholesterol, is likewise considered^{12, 33} a factor in accelerating the rate of sedimentation. This may probably be explained by the fact that the lipid content of the plasma influences the viscosity of the blood.¹⁸

Diagnostic Measures Employed In Thyroid Disorders

In connection with the lipid theory referred to above, it is pertinent that a considerable amount of investigation has been undertaken in relation to the cholesterol content of the blood in disturbances of the thyroid gland.

Mason, Hunt, and Hurxthal³⁵ have published results of a study of seventy patients with disorders of this nature. They found a consistently lowered blood cholesterol in hyperthyroid subjects, and a markedly elevated level in cases of hypothyroidism, and true myxedema. The maximum blood cholesterol level for normal persons, as accepted by one of these investigators,³⁷ is 230 mg per 100 c.c. In forty-seven hyperthyroid cases, the average level was 130 mg, in twenty-three instances of hypothyroidism it was 321 mg per 100 c.c. These findings suggested that an estimation of cholesterol values might be employed as a diagnostic aid in these conditions, to corroborate the clinical symptoms (particularly in hypothyroidism) in place of basal metabolic determinations generally applied, and which they found unreliable. Grabfield and Campbell³⁸ also observed a disparity between the basal metabolic rate and blood cholesterol values in thyroid disturbances.

Low cholesterol determinations in hyperthyroidism, and high values in hypothyroidism or myxedema are reported by Lahey,³⁹ but inasmuch as hypocholesteremia occurs in infection, malignancy, emaciation, leukemia, and with vegetable diet, and since hypercholesteremia is present in nephrosis, diabetes, and in some cases of arteriosclerosis, he feels that diagnosis on this premise is unreliable. He believes that blood iodine determinations are a more valuable index of thyroid activity, and refers to a micro-method of blood iodine determination.⁴⁰ Mahon⁴¹ concurs in this opinion, believing the significance of blood iodine in thyroid disease to be similar to that of blood sugar in diabetes mellitus and of blood calcium in parathyroid diseases. On the basis of a study of various laboratory methods in thyroid conditions, he concludes that findings in connection with the sedimentation rate—in instances of hypothyroidism especially—are too variable to be of value.

A wide diversity of opinion has, in fact, been expressed in the various published articles concerning the dependability of the sedimentation rate in thyroid derangements.

Von Balden²⁵ following a study of forty cases of Basedow's disease, found a similarity in the rate of sedimentation in this condition with that of simple goiter. She regards the procedure as valueless not only as a means of differential diagnosis, but as a guide in the administration of iodine or thyroidin.

In thirty cases of hyperthyroidism, Castex and Schteingart⁹ obtained normal, increased, and decreased sedimentation rates. No parallelism was found to exist between the blood sedimentation velocity, the basal metabolic rate, and the clinical symptoms. Being influenced by so many factors, they hold that the sedimentation rate lacks diagnostic or prognostic value in thyroid disease. Rosa and Furtado²² arrived at similar conclusions. From observations in 136 cases of various types and stages of thyroid disorders, Schein²⁰ also concludes that the velocity of blood sedimentation shows no relations to the basal metabolic rate and that it is unreliable in determining the effect of treatment. Hufschmidt²⁴ also regards sedimentation rate as an impractical therapeutic index. A normal sedimentation

ERYTHROCYTE SEDIMENTATION RATE

Diagnostic Value in Thyroid Disease—Clinical Observations and Survey of the Literature

RALPH R MOOLTEN, M D, F A C S and B A GOODMAN, M D, F A C S,
New York City

From the Thyroid Clinic of the New York Post-Graduate Hospital Columbia University

Variations in the settling rate of the erythrocytes are believed to have been observed originally by Galen, who called attention to the formation of a buffy coat, the so-called "crusta phlogistica." Little notice was accorded this phenomenon, however, until 1771, when William Hewson¹ and, somewhat later, John Hunter² (1794), pointed to its frequent occurrence in inflammatory conditions, noting that rapidity of sedimentation was directly proportionate to the degree of inflammation present. Interest in sedimentation velocity again lagged until revived by Fahraeus³ in 1918 and Linzenmeier⁴ in 1920, who regarded it as a diagnostic feature in pregnancy and various other conditions. Although it has since been employed as a diagnostic and prognostic measure in numerous pathological states, a considerable amount of disagreement still exists as to its definite value.

Literature In Connection With Sedimentation Velocity

The majority of articles on the erythrocyte sedimentation rate have appeared within the past fifteen years. Gram,⁵ Westergren,⁶ Friedlander,⁷ Ito,⁸ Meeker,⁹ Cutler,¹⁰ Polak and Mazzola,¹¹ Katz and Leffkowitz,¹² and Schulten¹³ are among those who have presented early contributions on the subject, more recently, Bendien and Snapper,¹⁴ Bannick,¹⁵ Goldemberg,¹⁶ Gilligan and Ernstene,¹⁷ and others. In surgery, Grodinsky¹⁸ and Lesser and Goldberger¹⁹ have studied the sedimentation rate in a variety of states. Increased interest in sedimentation velocity in connection with disorders of the thyroid gland has been evidenced within the past decade by the numerous articles which have been published both here and abroad. Outstanding among these are contributions by De Courcy,²⁰ Mora and Gault,²¹ Rosa and Furtado,²² Holboll,²³ Hufschmid,²⁴ von Balden,²⁵ Taterka and

Goldmann,²⁶ Munzer,²⁷ Tschernozaton-skaia,²⁸ Caste\ and Schteingart,²⁹ and Schein.³⁰

Theoretical Considerations

The blood sedimentation rate is a non-specific test which shows acceleration in various conditions, particularly those accompanied by inflammatory and tissue-destroying processes. It is dependent upon the suspension stability of the red blood-cells, there being an inverse ratio between the settling of the red cell corpuscle and the viscosity of the plasma.

Various theories have been advanced to account for this phenomenon and, undoubtedly, a combination of factors is responsible. Blood volume and red blood-cell count are believed to play a role, and blood gases, namely oxygen and carbon dioxide (as pointed out by Fahraeus,³¹ Ito,⁸ Meeker,⁹ and others) may likewise influence the rate of sedimentation, as may electrical reaction in the erythrocytes, as suggested by Fahraeus,³² Linzenmeier,⁴ Katz and Leffkowitz,¹² Grodinsky,¹⁸ and others. Tsunashima's experimental studies³³ suggest that the thyroïdin may affect blood sedimentation. Investigating the action of the spleen and the thyroid, he holds that the latter probably has the function of augmenting sedimentation which is restricted by the spleen when they are operative in the function of blood-making, similar to the different influences of these two organs on the bone marrow.

A disturbance in the plasma proteins, however, has received almost universal acknowledgment as being the chief factor in influencing the sedimentation rate. Gram⁵ (1921) pointed to an increase in the fibrin content of the plasma in the majority of infections and in various other disturbances, with a corresponding increase in the sedimentation speed. These findings have more recently been corroborated by Gilligan and Ernstene,¹⁷ in a

more dependable method than is determination of the basal metabolism in judging the effects of treatment in Basedow's disease. They also consider the blood sedimentation rate helpful in gauging therapeutic effects, and believe it may be used in estimating the quantity of thyroidin required in hypothyroid cases.

In the treatment of obesity with thyroidin, Holböll¹² found that, in ten out of twenty-five cases, clinical symptoms of hyperthyroidism supervened. A definite acceleration in sedimentation rate occurred in these cases, with no demonstrable increase in basal metabolic rate, blood-pressure, or leukocytosis. He believes that blood sedimentation velocity of the red cells is of definite help in following the course of a thyroidin-treated patient. It would have been of interest for Holböll to have checked these results with plasma protein readings in these cases, to determine whether the thyroidin produced the increase in sedimentation rate *per se*, or indirectly by changing the albumin-globulin ratio.

It readily becomes apparent that no definite consensus of opinion exists as to the value of the erythrocyte sedimentation rate as a diagnostic criterion in thyroid disease. This diversity of findings and opinions prompted the present study

which was undertaken as an unbiased investigation, to provide additional corroborative data on either phase of the subject.

Present Series

One hundred unselected clinic cases with thyroid dysfunction comprised the series. It included a variety of types of goiter designed as diffuse and nodular, toxic and nontoxic. Clinically classified, based upon secretory function, they may be divided as shown in Table I.

Technic. Of the three most widely used methods (the Linzenmeier,⁴ the Westergren,⁶ and the Cutler⁹ methods) the Cutler technic was employed in the present series.

Exactly 0.5 c.c. of three per cent sodium citrate solution is placed in a syringe, into which blood (obtained by venipuncture) is drawn up to the five c.c. mark. The blood and citrate solution are thoroughly mixed by shaking the syringe back and forth several times, the needle having been removed from the syringe to avoid the possibility of introducing clotted blood. The contents of the syringe, the measured quantity of citrated whole blood, is then discharged into a calibrated five c.c. sedimentation tube graduated into tenths and marked in millimeters. Each tube is numbered to avoid possible error, and all samples of blood are brought to the laboratory in a rack. Before readings are made, each tube is stoppered with a paraffin-coated cork and gently inverted two or three times to insure a uniform distribution of the erythrocytes, since in some tubes marked sedimentation might already have taken place. Readings should be recorded within ten hours, as the sedimentation phenomenon begins to disappear after that time. The level of the settling column of blood cells is noted every five minutes for a period of one hour and its position marked on special sedimentation charts, on which horizontal lines represent divisions on the sedimentation tube and vertical lines, the intervals of time. In this way a graph is traced which shows the position of the sedimentation column at any period during the first hour. The more vertical the curve the more rapid is the sedimentation rate. The graphic method is perhaps the most

rate was observed in fifty per cent of his series of thyrotoxic cases, in only 4.6 per cent of the observations did it exceed thirty mm during the first hour. Munser²⁷ found parallel determinations of sedimentation and basal metabolic rates in thyrotoxicosis in only fifty-nine per cent of his cases. This he attributes to variations in the two procedures, which he believes do not concern the same pathological processes. He accepts the sedimentation test as significant only in cases showing accelerated rate, otherwise he considers the metabolic rate more dependable. Goldemberg's findings¹⁰ in a series of 195 cases are in approximate agreement with those of Munser, showing a parallelism of these tests in sixty-one per cent of his series. In forty-four per cent both tests were normal, in seventeen per cent both were accelerated. In his opinion the sedimentation rate of the erythrocytes is of value only when considered in conjunction with the clinical symptoms and with the basal metabolic rate. He believes that even if the sedimentation rate is normal, hypothyroidism may still be present, unless the basal metabolism is also normal. Bannick¹⁶ cites a case of exophthalmic goiter in which the basal metabolic rate was plus forty-six, the sedimentation velocity, five mm in the first half hour, and twelve mm in the first hour (closely approximating the rate for normal individuals, which he arbitrarily established as fifteen mm in the hour). He would therefore exclude employment of the sedimentation rate in mild or moderately severe cases of thyrotoxicosis. It seems to us, however, that findings in only one case are rather inadequate as a basis of conclusion.

Little or no acceleration in sedimentation speed occurred in cases of toxic thyroid observed by Grodinsky,¹⁸ on the other hand, considerable increase was noted in the other toxic and malignant conditions. He therefore concludes "that the toxins of infections and malignant conditions produce changes in the blood plasma that permit an accelerated sedimentation time, while the endocrine secretions, normal or abnormal, have no such effect."

Prior to operation, the rate of sedimentation was increased in all of the

thirty cases of thyrotoxicosis observed by Mora and Gault.²¹ Following the administration of iodine, the speed was decreased in six out of eleven cases, and increased in five. Thyroidectomy caused acceleration of the rate in thirteen, and a reduction in fourteen cases. According to these authors, "there seemed to be little parallelism between the sedimentation velocity, the basal metabolic rate, and the clinical picture."

Again, there are those who favor or enthusiastically regard sedimentation as a valuable index of thyroid activity. Included in this category are De Courcy,²⁰ Tschernozatonskaia,²⁸ Taterka and Goldmann,²⁹ and others. De Courcy's article is particularly outstanding in this connection, in which he states that "in the blood settling test we have a very sensitive test which, when embodied with other methods, becomes a very valuable aid to diagnosis and an accurate check to prognosis. It is especially valuable in differentiating between toxic and non-toxic states in goiter, toxic goiter and tuberculosis, pregnancy and myoma."

One of the largest series studied is reported by Tschernozatonskaia who, following both experimental and clinical investigation, was greatly impressed with results attained through the employment of the blood sedimentation rate in thyroid disorders. Among 646 cases, he found ninety-seven with hyperthyroidism who showed an acceleration of sedimentation velocity ranging from ten to forty-five mm in the hour (normal of five to eight per hour by the Pantchenkoff technic). Of 528 cases of endemic goiter associated with different forms of dysthyreosis, there were 487 with accelerated sedimentation rates, twelve with normal rates, and in twenty-nine the rate was prolonged. Tschernozatonskaia emphasizes the importance of repeated determinations. He regards them as a reliable guide in the treatment and prognosis of different thyroid diseases, inasmuch as a marked deviation of the sedimentation rate from the normal points to an advance of the morbid process, while approach to the normal rate is an indication of improvement.

Taterka and Goldmann hold that determination of the sedimentation rate of the erythrocytes is a more simple and

GRATITUDE FOR UNPLEASANT ADVICE

It is very seldom that a physician is thanked for giving advice which is unpleasant and displeasing to a patient. The Journal of the Indiana State Medical Association prints a letter which an Indiana physician received from an anonymous patient only a short time ago. As the physician himself says, this one letter compensates him for innumerable times that he has been bitterly condemned for giving similar advice to patients who have consulted him in a venereal clinic. The letter follows:

"Dear Doctor

"About a year ago I asked your advice concerning marriage with a young man who was then, and I suppose still is, receiving treatment at your clinic. I knew all the facts of the case, but felt that if there was any chance at all of complete recovery, I was willing to wait. You gave statistics on this particular kind of disease and told me that an absolute cure, in this case, was very doubtful and due to the fact that the brain had been affected, a recurrence was not improbable. You told me the best thing I could do would be to find someone else and forget this young man as far as marriage was concerned.

"That very night I told the young man

that I thought under the circumstances we had better forget any plans for the future and, while we had no reason to be angry with each other, the best thing for us to do would be stop going out together. It was the hardest thing I ever had to do because I believed that I did care greatly for him. But your advice was too sincerely given to disregard.

"Since then I have met a young man of good character who comes from a good family. He is clean and fine, Dr ———, and I shall marry him soon. I can never thank you enough for the time you gave me when you talked to me as you did. Even outside the fact that the first young man was diseased, I know now that I never really cared for him the way I do for my husband-to-be.

"You saved me from a dreadful mistake and probably a lifetime of misery. If everyone would listen to your advice which you give so readily and convincingly, I'm sure many young people would be kept from a lot of sorrow.

I repeat, Doctor. I want to thank you a thousand times and over because I probably owe my life's happiness to you. You asked for no names when I called upon you, so that is why I shall leave this unsigned."

informative for the study of the sedimentation rate. A composite graph obtained in our series is shown in Chart I.

Results in the present series. A parallelism between rapid sedimentation curves and high basal metabolic rate was observed in the early cases of our series. Deviations, however, became apparent as the number of observations increased. Some patients with marked thyrotoxicosis and elevated basal metabolic rates showed normal or even subnormal sedimentation curves, while in other cases of

proved more reliable as an index of thyroid disease than the erythrocyte sedimentation rate, the latter being of no practical value as an aid in diagnosis.

Summary and Conclusions

1 The erythrocyte sedimentation rate is a nonspecific test whose velocity is increased in the presence of inflammatory and destructive processes. It is accompanied and probably due primarily to an alteration in the globulin-albumin ratio of the plasma proteins.

CHART I—COMPOSITE GRAPH OF SEDIMENTATION CURVES (CUTLER)
100 CASES THYROID DYSFUNCTION

nontoxic goiter with normal or minus basal metabolisms, the sedimentation rate was rapid.

A study of the Chart shows considerable overlapping of curves, the line in many instances representing the sedimentation rate of more than one case. An analysis of these curves reveals certain inconsistencies. A normal sedimentation rate was observed in approximately sixty per cent of the cases, irrespective of the degree of thyroid alteration or of basal metabolic rate. The remaining cases were distributed in both extremes of very slow and very rapid sedimentation rates, there being more of the latter. In neither group, however, was there absolute correlation of retarded sedimentation rate with low basal metabolic rate, or of accelerated settling rate with elevated metabolism.

The basal metabolic rates in our cases

2 A survey of the literature shows no consensus of opinion as to its value as a diagnostic aid or as a guide to therapeutic procedure. Although many observers have noted changes in the blood sedimentation rate during the administration of thyroidin, no definite value can be attributed to this test, since results in large series of cases have been so variable.

3 In the one hundred cases which constitute the basis of the present article, no consistent parallelism was found to exist between the basal metabolic rate, the blood sedimentation rate, and the thyroid entities.

4 Our results coincide with the opinion of those investigators who find the erythrocyte sedimentation rate an unreliable index of thyroid activity.

115 E. 82 St
125 E. 63 St

most other writers in that we found comparatively few complications and sequellae after injection treatment. We believe that with care and a previous accurate knowledge of the anatomy and technic that this method is not fraught with much danger. Peritonitis has been described after injection of the solution too deeply. This has been a very rare occurrence and should ordinarily be avoided. Atrophy of the testes was observed only once in our series and then it was slight in degree. Impaired sexual power was complained of by three patients, although it must be explained on a functional rather than an organic basis.

Fatalities are exceedingly rare if one judges by reports in the literature. Fowler found only four in some 30,000 reported cases. None of our cases died as a direct result of injections although the method may have been responsible indirectly for a fatal outcome in the following case.

Male, aged fifty-four, received five injections in our clinic. He then disappeared and turned up later at another hospital where an operation was performed, apparently the operation was fraught with unusual difficulties because the femoral vein was injured necessitating a later amputation of the thigh. The patient finally succumbed to pulmonary embolus.

Experimental Work

Results of experiments on animals have been cited to demonstrate the response of tissues to the irritating effects of various solutions. Microphotographs reveal the tissue reaction and fibroblastic proliferation which follows. Kelly of Detroit has done considerable work along this line and his microphotographs taken from sections made at varying intervals after injections in dogs are of great importance. They show that while early changes are well-marked, the reaction subsides and the tissues return to a more or less normal state with the lapse of time. In a personal communication, Kelly states

I am sure that if we could maintain the original condition which we produce, and which you have found clinically and we have found in our dogs, that we could cure a large percentage of hernia. However, no solution has yet been devised that will

maintain this tissue. I am not as yet, however, convinced that such a solution may not be devised.

Findings at operation after injection method had failed. We were much interested in the opportunity afforded us to observe the gross appearance and to study microscopic sections of the various layers in cases previously injected without success. In all, ten such patients came to operation. There was a variation in the interval elapsing between the last injection and the operation but in all a sufficient period of time had elapsed to permit the early proliferative changes to subside. In no case did we find the clinical or microscopic evidence of a strong bulwark of built-up scar tissue, such as is claimed by many to be the result of injection treatment. In one or two cases some strands of connective tissue partially occluded the opening of the neck of the sac. There was some increase in the fixation of the external oblique aponeurosis to the underlying muscle and conjoined tendon, but in the main, there was little residual evidence of efficient conversion of weak areas of the abdominal wall into strong resistant layers. In fact, for the most part, there was little evidence of any residual tissue reaction of consequence. (Table I)

Results of injection treatment. The immediate results in most of our cases were gratifying, that is, impulses disappeared, the areas felt strong, and the patients regarded their hernias as controlled. In the majority of instances, this result was maintained for several months. Thereafter, however, the condition gradually reversed itself until eventually most of the hernias were again felt by the patient and the examiner to have approached the situation present before the injections were begun. One or two patients appeared to be cured for a longer period, one for over a year after removal of the truss but in this case, the hernia then "recurred" and was recently operated upon.

The results in this series of sixty-six patients with ninety-two hernias are as follows

First case injected on October 31, 1934
Last case injected on October 5, 1936
Of the 66 cases, 4 died, 6 cannot be traced

INJECTION TREATMENT OF HERNIA

BRADLEY L. COLEY, M D, *New York City*

Medical history reveals that many of the various methods of treatment employed, some at the present time, have run a cyclic rather than a continuous course in popular usage and favor. This may be said to be true of the injection treatment of hernia—a method having considerable vogue at the present time. Succeeding generations have witnessed a revival of this method, with, perhaps, some variation in the formula used. Velpeau, more than a hundred years ago, in an effort to cure hernia by sac obliteration, first practiced the method of injecting irritating solutions. Prior to 1844, Pancoast used iodine and tincture of cantharides in thirteen cases. Heaton in 1842 tried tincture of iodine. In recent years, Pine-Mestre of Barcelona, Spain, in an enormous number of cases has tried an original solution of vegetable extracts, mainly tannic acid derivatives. Fowler of New York has done considerable work in this field and has written extensively on the subject. Quillin, Bratrud, Harris and White, Ross, McMillan and Cunningham—all have contributed to our recent knowledge of this form of treatment.

As to the *technic* of injection, this has been described in detail so often that it is unnecessary to repeat it here. Suffice it to say that before commencing the injections it is necessary to provide the patient with a truss that fits snugly and holds the hernia completely reduced at all times. This in itself is no mean task since experience has shown that at least seventy-five per cent of truss-wearers fail to maintain complete reduction of the hernia. The truss must be worn continuously day and night for at least one month from the date of the first injection, thereafter, for six months during the day time, and some writers have insisted on an even longer period. Injections are made usually two or three times a week until from ten to twenty have been given. Patients are supposed to be able to continue at their usual occupations.

Indications for Treatment

Opinions vary considerably as to the indications for injection. Some writers include all reducible hernias that are susceptible to complete retention of the hernia by a properly fitting truss. They use the method for umbilical, femoral, and postoperative ventral hernia, as well as for inguinal hernia both indirect and direct in type. Others exclude all but simple indirect inguinal hernia. Our view is that only the indirect inguinal hernia or small recurrent inguinal hernia (usually direct in type) that is readily reducible and completely retained by the truss should receive injections. We would exclude all other forms.

Ross recognized the following indications:

1. Conscientious objectors to surgery
2. Economic reasons (a) Time saved from hospitalization (b) Cost of hospital care saved
3. Elderly people
4. Other poor surgical risks
5. Recurrent hernias

Contraindications include sliding hernia and hernia associated with mal descent of the testes. Ross recognized the following:

1. Adherent nonreducible types
2. Large ventral and umbilical hernias
3. Femoral hernias (cannot be held with a truss and are too near the femoral vein)

Theoretically it would seem that indirect inguinal hernia in children below the age of sixteen, should be particularly favorable for injection, for the occasional apparent cure in such cases by the simple wearing of a truss is known to all. However, we are not familiar with any statistics that would indicate that injections have been employed extensively in young children. The difficulty of maintaining constant application of the truss at all times in these young individuals must be obvious.

Complications

Our experience coincides with that of

(2 well from 6-16 months 9 well from 13-23 months) But nine of the eleven are still wearing trusses and will not remove them, leaving

Probable Cures two or 3.44 per cent

Conclusions

1 The injection method, while old, has recently been revived and is commanding widespread attention

2 The advantages claimed for it include elimination of risk of operative

fatality and of postoperative complications, an economic saving by virtue of no loss of wages during hospitalization and postoperative care, and no hospital expenses

3 The disadvantages are the prolonged period required for treatment during which the truss must be constantly worn, the uncertainty of the method, and the high percentage of failure to produce a complete cure of the hernia

4 The basic principle of the injection method is the production of fibroblastic tissue, or, in reality, of scar-tissue formation. Scar tissue notoriously tends to stretch and is weaker than normal tissue. The likelihood of a permanent cure, therefore, is slight except in those cases in which the fortuitous obliteration of the neck of the sac is produced by agglutination of the peritoneal surfaces. It seems

ROTATED FIBULA

J J KIRSCHENMANN, M D, Brooklyn
From the Surgical Service of the Norwegian Hospital

This is a condition not considered in standard texts. The term was coined and my attention first called to it (about ten years ago) by Dr John J Masterson, radiologist at the Norwegian Hospital. The name implies a tearing of the calcaneo-fibular, anterior talofibular, the anterior and posterior lateral malleoli ligaments, and the interosseous ligaments allowing the fibula at the inferior tibiofibular articulation to rotate outward and posteriorly. Clinically it is usually diagnosed as a severe sprain as the radiologist reports it negative for fracture. Careful study of the x-ray, however, will show the fibula pulled out of the groove at the fixed tibiofibular syndesmosis. I prefer to call it a rotated or dislocated fibula.

Etiology

This condition is caused by the patient turning on his ankle while bearing weight. The astragalus twisting in its joint between the malleoli, spreads the malleoli apart. The ligaments about the lower end of the fibula, being weakest, give way, allowing the fibula to rotate. I believe that in most severe sprains there is interference with the inferior tibiofibular joint. But in only those cases where the space between the fibula and tibia syndesmosis is visualized by x-ray do I use the term rotated fibula.

Diagnosis

There is a history of the patient turning on his ankle with the resultant pain,

swelling, and inability to walk. There is marked swelling of the ankle below and anterior to the fibula which extends up between the tibia and fibula a distance of two or three inches accompanied by a visible bony broadening between the tibiofibula malleoli independent of the soft part swelling. Tenderness is found in any sprained ankle, plus severe tenderness along the lower two or three inches to the medial side of the fibula. There is practically no tenderness over the bone itself. On further palpation the posterior inferior surface of the fibula, at the lateral malleolus, is further posterior than in the uninjured ankle.

X-rays show the fibula pulled out of the groove (Fig 1 and 2)

Treatment

Traction is applied for five minutes to produce relaxation. With the thumb on the fibula malleolus, the malleolus is pushed anteriorly and inward. When it is heard to snap into place the foot is flexed on the ankle and inverted. This forces the external anterior protuberance of the tibia against the fibula while the peroneus longus and brevis are made tense forcing the fibula against the external anterior protuberance of the tibia (Fig 3-8). A cast is then applied from the toes to the lower third of the leg. The cast is left in place for four weeks. The ankle is then strapped in flexion and inversion and gradual weight-bearing allowed. The

Fig 1 Normal left ankle, female, age twenty-one

Fig 2 Right ankle, same patient as Fig 1. Rotated fibula.

Fig 3 Rotated fibula, girl, age thirteen, before correction

most unlikely that strong and lasting tissue could be "built up" by the injection method thus converting weak musculature and thinned-out aponeurosis into competent resistant abdominal layers

5 The success of the method should be judged by careful follow-up records based on physical examinations such as have been used to evaluate the results of surgical operations

Comment

The glowing accounts of economic saving accomplished by the injection method must be carefully scrutinized. True, the arguments brought forward by the proponents of the method, *viz* economy resulting from no loss of time from work, no hospital bills, and the absence of risk of mortality, are cogent ones. However, when it is realized that a fair proportion of operable cases have undergone a course of injections without success and have subsequently required an operation, the arguments lose some of their force. Assuming that, say, seventy-five per cent of the injection failures require a subsequent operation, it is seen at a glance that the cost of injecting the entire group plus the cost of subsequent operations on the failures, far exceeds the sum expended for immediate operation upon the entire group.

This brings up a fact frequently emphasized by advocates of the injection

method, *i e*, the considerable proportion of failures following operative measures. No one who has had a large experience in hernia surgery can disregard the fact that traditional operations for hernia do have a large recurrence-rate. Of course, the percentage of failures varies somewhat with the technical skill of the surgeon, but—and what I believe to be even more important—it varies with the accuracy and the time interval of the follow-up record. Only those statistics that are based upon actual follow-up examinations (not communications) made at least one, and preferably two years after operation, are of the slightest value. Such statistics seem to be conspicuously lacking in all of the recent articles favoring the injection method. Until some clinic brings forward a series of consecutive injection cases traced and examined and found to be free of evidence of hernia two years after the removal of the truss, we are still without authoritative data on which to base an opinion regarding end-results. These figures should be forthcoming from sources such as Bratrud's clinic in Minneapolis or Quillin's in Chicago. In the meantime, lacking these comparable results, I feel that the profession is not justified in offering the injection treatment to patients with operable inguinal hernias as an alternative to surgery.

140 E 54 St

A BIG DRIVE FOR HEALTH AND WELFARE

Between mid-October and the end of the year, 398 American cities, representing approximately two-thirds of the country's urban population, will raise community funds to maintain their private health and welfare services. Through the generous cooperation of a few advertisers of national reputation, the facilities of the regular commercial broadcasts of these organizations will be dedicated by them to reminding the great radio public of the importance of this Community Mobilization for Human Needs. The community chests in these 398 cities

support a multitude of community activities which, though of vital local necessity, are not financed by government tax funds. These chests raised \$80,000,000 last year.

The local agencies thus financed, including among others hospitals, youth organizations and settlements, are sponsored by Protestant, Catholic and Jewish, as well as civic, business, labor, and other non-sectarian groups. They provide hospitalization, public health nursing, child care, family welfare, and other basically important community services.

A well-known New York physician was having an old x-ray machine taken out, and the worker, stripped to the waist, was clambering about among the wires and pipes overhead, when a friend of the doctor came

in, "What's that fellow doing up there?" he asked. "Sh-h-h!" whispered the doctor, "that's one of my patients that I have just fitted with monkey glands, and he thinks he is climbing a tree."

DENTAL CARIES IN CHILDREN

Clinical Control

I NEWTON KUGELMASS, M D, *New York City*

Rational control of dental caries is preventive rather than reparative. It requires not only the services of the dentist but also those of the pediatrician and obstetrician, if the proper anlage is to be laid from conception. But even with supervision dental caries occurs throughout infancy and childhood. It is explicable on the basis of the thirty factors or more that produce various types of dental caries. As a consequence of the various permutations and combinations of these factors about three million conditions become possible in the daily formation of tooth decay in children. Clearly there is but one state of dental health and many states of dental caries that, according to the theory of probability, the chances appear all against dental immunity.

In the medical management of dental caries in children we have in the last decade formulated a therapeutic plan based on the determining factors—constitutional, endocrine, metabolic, nutritional, and oral. To illustrate the procedure we grouped one hundred children with caries-susceptibility with an equal number with relative immunity. Such a comparison of extremes with respect to tooth decay helped to check specific factors present in one group and absent in the other. Children with dental caries were treated locally and systemically as would any child with an inflammatory process somewhere in the body. Since there is no specific preventive measure universally applicable to all children with dental caries we adapted current practices according to individual requirements.

I Constitutional Factors

We observed that seven out of one hundred children with dental caries had a familial susceptibility to the disease. The mothers of these children each received competent prenatal supervision. Dental caries prevailed in most members of the family despite rational dental and medical measures for its arrest. Caries persisted in these otherwise normal children de-

spite the rigid therapeutic procedures outlined below. The arrest in caries was transient, exacerbations following alimentary, infectious, and emotional disturbances. On the other hand we observed that nine out of a hundred children free from caries had an individual immunity to the disease. Six of these children came from families with sound teeth and three of them appeared to resist caries despite the prevalence of caries in other members of the family. Three of this group resisted caries in spite of unfavorable dietary and hygienic measures. Constitution thus appears a significant factor in susceptibility and immunity to dental caries. Clinically no distinctive features have been discerned characteristic of either group, i.e., sex, race, body build, bony contour of head or skin coloring.

But the teeth of these children are distinctive physically and chemically. In the caries-susceptible group there are steep cusp-inclines and food impacting areas while some teeth are more susceptible than others because of chemical differences. Brothers and sisters apparently differ in susceptibility or immunity to caries depending upon the dental pattern inherited. The dental structure of one side of the family may be susceptible to caries and that of the other immune. Whichever of these types of dental structure the child inherits he becomes predisposed or immune to caries. On this basis dental caries may be explained in this small group by Mendelian segregation.

Development of teeth depends on the character of the anlage, the adequate supply of calcium, phosphate and basic minerals, the materials from which teeth are made, and finally the regulatory hormones, vitamins, and other materials in the circulating fluid favoring tooth formation. The character of the anlage is determined chiefly by heredity. Embryologically the tooth is formed first and then bone around it. Teeth are thus structures surrounded by bony framework whose development depends mostly upon that of the teeth. Their maintenance

Fig 4 Same as Fig 3, after correction

Fig 5 Rotated fibula, left, boy of eight

Fig 6 Same as Fig 5, after correction

patient usually completely recovers at the end of six weeks

Comment

My early diagnostic experience with this condition was purely one of x-ray. It is only in the past three years that I have been able to diagnose it clinically and show it to others that they could diagnose it before x-rays were taken. I have

seen numerous cases that were never reduced (Fig 9 and 10) and several that I was unable to reduce a few years back. These people continue to have pain and discomfort for months after their injury.

In this paper I have dealt with a rotated fibula only. It is not uncommon to find it associated with a fracture of the lower end of the tibia or fibula. In this event reduction is not as essential as the callus formed about the fracture seems to unite it to the tibia. This prevents the pain in later weight-bearing.

Summary

A condition of rotated fibula is presented which has a distinct pathology, diagnosis, and treatment. In view of this I believe that it should be classified as a clinical entity.

remained arrested provided the children were maintained on optimal dietaries

In contrast with these caries-susceptible children with endocrine disturbances we observed a number actually resistant to caries—six with adiposogenitopituitarism, one with hyperpituitarism, and one with hyperthyroidism. Only three of these children had previously been maintained on dietaries considered preventive of dental caries. Curiously enough all of them remained free from caries despite periodic effort to reduce their weight by dietary restriction. Some endocrinologists maintained that children with Froehlich's syndrome are immune to caries, and Boenheim⁸ refers to cases of hyperthyroidism as having sound teeth. Most of the observations on the dental status of children with endocrine disturbances bespeak rampant caries.

Formation and development of teeth are regulated by the endocrine system as are other bodily structures. Growth is under the influence of the anterior lobe of the pituitary gland, the thymus, gonad and adrenal cortex, and differentiation is regulated by the thyroid gland. In healthy children these two functions proceed in proper relation to one another and any discrepancy in their rate of progress results in developmental defects. There is a tendency, however, to ascribe an observed dental disturbance to a particular gland. Actually, however, a dysfunction in any one gland shifts the entire endocrine equilibrium to the extent that the whole system is at fault. Practically, however, there is one determining gland where functional correction brings about a more or less complete endocrine equilibrium. Whatever the glandular disturbance, dental caries is necessarily a secondary manifestation.

In hypothyroidism the structure of the dentine and enamel is abnormally soft. There is an extreme degree of root absorption and the crowns of the teeth lack density. Roentgenograms show marked decalcification of the superior maxilla. The improper development of the teeth predisposes them to caries. The thyrogenic basis for dental caries has been demonstrated⁹ conclusively by investigators in goitrous regions—Switzerland, Austria, southern Germany, and the mid-western states.

In hyperthyroidism the enamel is ex-

tremely poor, the dentine eroded and brittle because of the negative calcium balance characteristic of thyroid overfunction. Hence the tendency to tooth decay. Sattler maintained that the disposition to caries is due primarily to thyroid overactivity while Parhon¹⁰ attributes the caries to a dysfunction of parathyroid involved secondarily in hyperthyroidism. Particular emphasis must be placed on the administration of a high calcium dietary supplemented with vitamin D in order to safeguard the teeth from decay.

In hypopituitarism the lower teeth are considerably behind the upper producing a marked overbite. The lower front teeth are often crowded out of alignment because of the small size of the lower jaw. The teeth are small and delayed in development. Dental decay may prevail because of diminished density of the dental crown and the slow repair of tooth structures.

In hyperparathyroidism there is a generalized decalcification of the dentine as of all the bones. The dentine is soft and almost mushy in extreme cases which makes cavity preparation extremely difficult.

III Metabolic Factors

We have observed twelve children with dental caries secondary to metabolic disorders—two with cyclic vomiting, two with celiac disease, three with alimentary allergy, two with epilepsy, and three with chronic sinusitis. In contrast with this group there were eight children immune to caries—three with diabetes and five with hemophilia. In the former group, decay was not arrested until the metabolic condition was alleviated. The caries cleared three to five months thereafter but recurred with metabolic exacerbations. It became evident in the caries-susceptible group that the diet, apparently adequate in every essential, was not properly utilized. Valuable constituents were lost by vomiting, diarrhea or food intolerance because of some organ dysfunction. The necessary tooth materials may be brought by the blood stream to the teeth and still be unused. That which is absorbed and utilized rather than that which is offered is significant in body economy.

In dental metabolism Boyd, Drain, and

thus is determined primarily by the child's constitution and secondarily by local conditions

Hereditary predisposition to caries-susceptibility or immunity appears evident in some children. Certain families have sound teeth and others have defective teeth, and can be followed from one generation to another. Mellanby, Marshall, Toverud, and others observed that faulty structure predisposes to caries. May Mellanby¹ found eighty per cent of the carious teeth in children showed structural defects on histological examination. Hypoplastic teeth are rough and have pits and fissures as opposed to perfect teeth which have a hard smooth surface. Others, however, found that caries susceptibility is not determined by tooth structure. The most resistant teeth become carious, and poorly calcified hypoplastic teeth remain caries free under favorable conditions.

Heredity determines caries susceptibility irrespective of diet. Some of Bunting's⁴ caries-free children could eat any food or any quantity of sugar without a resultant increase in caries or in the *B. acidophilus* of the mouth. In the caries-susceptible children the disease could not be checked by adherence to any kind of satisfactory diet. Jay⁵ found that children hereditarily immune to caries remain free from lactobacilli regardless of the amount of sugar consumed. Considerable evidence exists in favor of clear-cut hereditary disposition of susceptibility or immunity to caries. Hess,⁶ however, demonstrated that children in orphanages with the most diversified heredity may nevertheless be kept free from caries on optimum dietaries.

Prenatal factors are important in predisposing children to dental caries. The teeth of infants begin to develop early in intrauterine life. Tooth germs of deciduous teeth have been demonstrated² in the embryo of ninety-two days, the first permanent molars at one hundred days, dentine and enamel at one hundred sixty-four days. At birth all of the temporary teeth are calcified to the extent of about twenty per cent of the total and the crowns of the permanent first molars practically none. Diet of the expectant mother appears to exert some influence upon the development of the temporary teeth. But

embryonic tissues possess an extraordinary growth impulse enabling them to remove required nutrient materials from maternal fluids in which the amounts present are minimal. The fetus thrives as a parasite irrespective of the mother's status. It is only when nutritional deficiencies are great that both fetus and mother are affected. The total calcium requirement per day is about one gram for the normal adult and the pregnant woman needs but one-tenth of a gram of calcium extra for the fetus. Prenatal care fails to protect many infants from dental caries of their deciduous teeth unless initiated early in pregnancy.

Dietary deficiency particularly in calcium and vitamins A, C, D in the expectant mother disturbs the early development of the teeth in intrauterine life. When the diet of the mother is deficient in calcium and in vitamins A and D, the alterations in the mineral composition of the teeth of the young are much greater than when the diet is deficient in calcium alone.

Neff observed extensive hypoplasia in deciduous teeth of infants as a result of deficient prenatal dietaries. Toverud and Toverud⁸ demonstrated the value of a balanced maternal diet for the teeth of the offspring. They observed a positive calcium and phosphorus balance on a daily intake of 16 and 20 grams respectively during pregnancy. Bloom⁷ gives dicalcium phosphate throughout pregnancy to improve the infant's resistance to caries.

II Endocrine Factors

We observed chronic caries in children with endocrine disturbances—six with hypothyroidism, two with hyperthyroidism, two with hypopituitarism, and one with hyperparathyroidism. Each of these children were under medical and dental care simultaneously. Every effort was made to clear the endocrine disturbance as well as maintain a favorable nutritional regimen outlined in Part IV. Nevertheless the arrest in caries was transient, readily disturbed by alimentary, infectious, and other illnesses because the metabolic status of these children remained unstable. But once they were in basal equilibrium with the determining endocrine condition under control, caries

testinal indigestion due to food hypersensitiveness can be prevented with the elimination of offending foods. It is the intolerance to food providing the fundamental constituents necessary for the maintenance of dental metabolism that is probably productive of decay in these three children.

In epilepsy, the convulsion of undetermined etiology, can be controlled by the ketogenic diet, which consists of a large amount of fat with minimal amounts of protein and carbohydrate. Although it can be made to fulfill all the nutritional requirements of the growing epileptic child it nevertheless tends to be acid-forming in mineral content and frequently inadequate in the mineral intake. As a result normal dental metabolism is interfered with as has been previously demonstrated. We have, therefore, offered ketogenic diets that are alkaline-forming in their mineral content and have thus been able to arrest caries once the convulsive seizures have ceased.

In chronic sinusitis, metabolic efficiency is impaired because of a series of disturbances. The initial focus of infection interferes with breathing, food intake, and gastric digestion. The focus gradually gives way to loci of infection with the alimentary and systemic absorption of the infection. With the abatement of the chronic sinusitis and improvement in the food intake and utilization, caries becomes arrested systemically.

IV Nutritional Factors

We found sixty-four fairly nourished children susceptible to caries, whose daily dietary did not fulfill optimal requirements. This group was in striking contrast with the sixty-six who showed immunity to caries on the basis of a daily dietary quite satisfactory in every nutrient requirement. In order to evaluate each of the nutritional factors, we made a differential study of the characteristics of the dietaries of both caries-susceptible and caries-immune children. Since the nutritional aspects of caries are concerned with carbohydrate content, acid-base equilibria, calcium, phosphate, and vitamins A, C, and D, the relative levels of these nutrients were determined for each child.

1 Carbohydrates Nineteen of the sixty-four caries-susceptible group were maintained on a high carbohydrate diet, while forty or the sixty-six of the caries-immune group were maintained on a low carbohydrate regime. From this there appears some significance in the role of carbohydrate in caries-immunity in comparison with that for caries-susceptibility. The carbohydrate content of the diet apparently has some influence on the health of the teeth. While experimentally sugar has never been demon-

Metabolic	12	8	Months
Nutritional	64	66	Weeks
Oral	7	9	Days

Stearns¹¹ found a definite relationship between adequate retention of calcium and phosphate and resistance to dental decay. There is thus a very close relationship between metabolic efficiency of the organism as a whole and tooth decay.¹² The diet be perfect and yet the teeth carious due to digestive, absorptive, and internal disturbances.

All the specific nutritional elements must be ingested as such or formed in the gastrointestinal tract from ingested food. The vitamins and mineral salts are taken in preformed while other elements represent altered food constituents. The formation, absorption or use of specific nutritional elements in the body is influenced greatly by numerous conditions, i.e., in-

sufficient intake, absence of some factor necessary for the formation of a specific nutritional element for food, excessive loss of gastrointestinal contents by vomiting or diarrhea, increased need in states of overactive metabolism, presence of a toxic state impairing absorption and utilization as in chronic infections, achlorhydria which affects absorption or production of specific factors from food, lowered metabolism in which tissues are working at an abnormally low speed, disturbed circulation.

Even under normal conditions the individual variations of metabolic efficiency explains in part the fact that under similar diets of borderline inadequacy some children are protected from caries and others are not. This is not only reflected in caries but as well in the composition of the teeth. Bowes and Murray¹⁸ have shown that the enamel decreases in the apatite content from ninety-two to eighty-six per cent with a corresponding increase in the phosphorus content with deprivation of mineral retention.

In cyclic vomiting there is a disturbance in the acid-base metabolism characterized by periodic vomiting, acidosis, and shock. The blood shows a low sugar, pH and CO₂ content. The urine is concentrated containing considerable acetone, diacetic and betaoxybutyric acid which cannot be ascribed to starvation. The two children reported were both allergic, the offending foods were eliminated and subsequently placed on a base-forming dietary with a minimal amount of acid-forming foods.

In celiac disease there is infantilism resulting from fat, carbohydrate, and mineral intolerance. Fats are digested but not absorbed and hence excreted in abnormal amounts as fatty acids and soap. Carbohydrates are not tolerated interfering with the assimilation of fat and giving rise to excessive fermentation of sugar and tympanitis. Mineral elements are not retained as a result of a growth defect and the absorption from the alimentary tract. Proteins are well-tolerated and constitute the essential part of the dietary in the initial treatment of the disease. Nevertheless the child may be maintained on a complete dietary or synthetic supplements of nutrient essentials.

In alimentary allergy the periodic in-

equivalent with each meal and by irradiation with ultraviolet light daily

There is some danger in feeding excessive amounts of calcium to children who do not require that amount. Although excessive intake will be excreted and not be absorbed the calcium in the alimentary tract will precipitate the phosphate and prevent its absorption thus interfering with the calcium-phosphorus metabolism. Masaki found that the calcification of the teeth depended upon the calcium-phosphorus ratio in the diet. Klein and McCollum¹⁷ found that low phosphorus diets favor susceptibility to caries. Animals fed on a low calcium-high phosphorus diet developed teeth properly calcified, but nevertheless free from caries. Klein¹⁸ also found that a high calcium-low phosphorus diet results in caries. Little consideration was given to the phosphate intake in the diet because it is available in adequate amounts in most foods provided its utilization is not diminished by excessive calcium compound administration.

4 Vitamin D Thirty-three of the caries-susceptible group showed some inadequacy in the daily vitamin D intake, either because of an insufficient intake or the ingestion of irregular amounts, or the use of unstandardized oils. Only ten of the caries-immune group were taking more than the required amount of vitamin D per day. Since no foods are rich in vitamin D, and egg yolk is the only important food source with lesser and variable amounts present in butter, cream, and milk, the children's diets were reinforced with synthetic sources of vitamin D. They were given concentrated sources of vitamin D, viosterol, irradiated concentrate made from halibut or cod-liver oil, vitamin D milk, and daily irradiation with ultraviolet light. We avoided overdoses of vitamin D not only because they diminish the appetite, but caused some of the children to be irritable, and produced allergic manifestations in others.

Mellanby prevented caries by the addition of fat-soluble vitamin particularly vitamin D in the normal diet of children. The Medical Research Council¹⁹ reports show that a high vitamin D content of the food tends to diminish caries incidence if given during the development of the teeth. MacBeath²⁰ found dental caries eight times more active in children not receiving ultraviolet irradiation than in the control group. The size of the dose of the cod-liver oil was found to be directly proportional to the degree of reduction of caries. Doses of three hundred units were more effective than those of one hundred and fifty units.

5 Vitamin A A relatively insignificant number of children revealed vitamin A to be

strated to produce caries either locally or systemically, the Bunting school¹⁸ has nevertheless correlated the carbohydrate content of the diet with the occurrence of *B. acidophilus* as the local etiological factor. Growth of the acidophilus of the mouth is extremely sensitive to carbohydrate in the diet as evidenced by the rapidity with which changes in the flora of the saliva takes place. The counts of acidophilus cultures actually increase or decrease within twenty-four hours paralleling the change in the carbohydrate, especially sugar above and beyond the adequate diet. Mellanby maintained that oatmeal contains a toxic factor which is productive of dental caries. Actually carbohydrates are harmful only when they comprise such a large proportion of the diet that inadequate amounts of other foods containing minerals and vitamins are taken.

We have given due credence to the carbohydrate content of the diet by diminishing it in the daily regime of the caries-susceptible children. The adequacy of the diet was assured by a glass of milk and a serving of raw or cooked food or both with each meal, servings of leafy and root vegetables with two, meals, egg, if tolerated, with one meal and meat fish or fowl with another, butter with each meal, and a teaspoonful of cod-liver oil with each meal. The additional foods were optimal with no food except fruit juices between meals. The use of coarse, fibrous, detergent foods was advocated for both masticatory and gingival stimulation. Anticonstipative drugs were contraindicated, particularly milk of magnesia which tends to produce decalcification by replacing the calcium content of the tooth with magnesium.

2 Minerals Of the one hundred children observed in each group forty-three with caries-susceptibility had been maintained on an acid-forming diet while forty-five caries-immune were on an alkaline-forming diet. It is rather significant that about two-thirds of the group whose relationship to caries was essentially nutritional should be so equally distributed with respect to a favorable or unfavorable mineral content in the dietary. The preponderance of milk, fruit, and vegetables in the dietary, alkaline-forming factors, is apparently effective in the arrest of caries. This parallels our previous observations¹⁴ as well as the work of Martha Jones¹⁵ who prevented tooth destruction or odontoclasia on a diet high in potential alkalinity, an excess of about forty cc of normal solution per day.

The children with caries were accordingly maintained on an alkaline-forming regime making each meal excessive in potential

alkalinity. The needlessly large amounts of cereal, meat, fish, egg, and cheese were displaced by milk, fruit, and vegetables. The alkaline-forming Mead's cereal and pabulum displaced oatmeal and other cereals, muffins of lima bean flour, raisins, dates, etc. replaced acid-forming bread, potatoes were substituted for rice and macaroni, fruit juices were offered between meals. Mild alkaline mouth washes were used after each meal.

3 Calcium Of the one hundred caries-susceptible children only twenty-two showed a diminished intake of calcium in the daily dietary while twenty-nine of the caries-

TABLE V—LOW CARBOHYDRATE DIET

Food	Age 6 years		Calories 1500		Carbohydrate dral (Gms.)
	Calcium 14 gms.	Protein 61 gms.	Phosphorus 14 gms.	Carbohydrate 100 gms.

					100

immune group appeared to take an excessive amount of calcium in their dietary. Thus about a third of the nutritional group showed some relation to calcium metabolism. The ratio is small but yet significant in the management of caries.

The diets of the children with low calcium intake were increased with sources of calcium by adding milk, cheese, leafy vegetables, especially turnip tops, water cress, and almonds. In most cases the problem was more of increasing the absorption of calcium from the food rather than increasing the total calcium intake. This was effected in the caries-susceptible children by offering buttermilk or lactic acid milk to favor the solution of calcium salts, by calcium diphosphate in acid fruit juices between meals by larger doses of 10 D cod-liver oil or its

tee against caries Klein and McCollum²⁰ found that coarse particles, lodged in crevices of the teeth, give rise to fermentation while the finely pulverized diet was readily washed away by the saliva Benst²⁰ showed that the self-cleansing properties in the mouths of children was preventive of caries It has been noted that fever patients are liable to an accumulation of sordes on the teeth due to the reduction of the flow of saliva with a consequent dry mouth Schnak²¹ cites a highly fermentable carbohydrate—Hawaiian food-stuff, poi, which is cohesive in the mouth and never clings to the teeth Hawaiian children have little dental caries It thus seems indisputable that sticky food of a fermentable nature clinging about the teeth and areas of stagnation is an important predisposing cause in the formation of caries It produces an acid tending to decalcify the enamel of teeth which are not immune to caries and lays them to attack by the exciting cause the B acidophilus organism

Proper masticatory stimulation is indispensable in the management of the child's oral hygiene Solid food should be introduced early in infancy to compel mastication, and the earlier the child is weaned from strained foods the better for the health of the teeth He should be taught to massage his teeth by chewing coarse food which favors secondary dentine deposit Breeze²² has demonstrated that trauma acts as an irritant to cause sclerosis of the teeth Coarse food scours tooth surfaces and the resistance to caries parallels the extent of sclerosis Nasal breathing should be maintained free in order to encourage proper chewing Food should not be washed down with milk but chewed, bread soaked in milk should be avoided

The work done by the teeth from day to day should be about the same, otherwise it lays the teeth open to decay²³ If the food is hard it should always be hard, if soft it should always be soft, the tendency being to shift it in the direction of fibrous food The transition from hard to soft food is dangerous but not the converse Fibrous foods consist of bacon, fish, meat and poultry, raw vegetables, lettuce, water cress, radishes, celery, stale bread toasted or twice baked, raw fruits This is in contrast with biscuits bread

cake, puddings, preserved fruit, jams, marmalades, syrups, chocolate, honey or cocoa There is universal agreement about the work to be done by the teeth which if inhibited is productive of decay

Oral cleanliness is of prime importance in controlling caries in children It reduces fermentation around the teeth which delays decalcification Dentrifices have little effect from chemical action in the prevention of decay Their only value lies in aiding to remove physically the bacterial accretion Detergent foods are not specific for immunity other than increasing the local cleansing of the teeth Drastic chemicals should not be used for tooth cleansing because they weaken the natural protection of the saliva Simple saline or precipitated chalk may be used as tooth powder

Conclusions

1 One hundred well children susceptible to caries were compared with an equal number relatively immune, in terms of constitutional, endocrine, metabolic, nutritional, and oral factors

2 Seven percent of the children studied had a familial susceptibility to caries while nine percent had an individual immunity The caries-susceptible children showed teeth with steep cusp-inclines and food-impacting areas paralleling the tooth structures inherited from one of the parents Susceptibility or immunity to caries of some children may be explained on the basis of Mendelian segregation

3 Ten percent of the children with chronic caries were observed in hypothyroidism, hyperthyroidism, hypopituitarism, and hyperparathyroidism in contrast with eight percent immune in adiposogenitopituitarism, hyperpituitarism, and hyperthyroidism respectively Tooth decay was not arrested until the endocrine disturbances were corrected

4 Twelve percent of the children with caries had metabolic disorders—cyclic vomiting, celiac disease, alimentary allergy, epilepsy, and chronic sinusitis in contrast with eight percent immune in diabetes and hemophilia respectively Tooth decay was not arrested until the metabolic conditions were alleviated, for that which is absorbed and utilized rather

a clinical factor in caries. Five of the caries-susceptible children showed a diminished intake in vitamin A while thirteen of the caries-immune were ingesting vitamin A in relatively excessive amounts. Vitamin A was readily reinforced in the dietary of children with dental caries by means of halibut liver oil without resorting to special food sources. Since the children with caries naturally fell into the group who received an inadequate intake of vitamin D there was no necessity of making special provisions for increased intake in vitamin A.

It has been amply shown that vitamin A is necessary in the synthesis of the soft dental tissues. Boyle found that lack of vitamin A leads to defectively calcified dentine and hypoplastic teeth. Mellanby and King²¹ found degeneration of the dental nerves with experimental animals fed on vitamin A deficient diets. Smith and Land found that vitamin A deficiency in animals caused dull white incisors subject to excessive abrasion which was preventable by the daily administration of cod liver oil.

6 Vitamin C. Twenty-four of the caries-susceptible children showed a diminished intake in vitamin C while forty-seven caries-immune children apparently ingested excessive amounts of vitamin C. Children with dental caries had their diets reinforced for vitamin C by increasing the amounts of fresh, raw and canned fruits and vegetables, particularly orange, tomato, and pineapple juices, salad greens, celery, raw cabbage, and carrots. There was no need for the therapeutic administration of ascorbic acid.

It has been amply demonstrated that vitamin C is necessary for the formation and maintenance of pulp and pericementum. Robb²² showed that the odontophores are affected in vitamin C deficiency. Rosebury²³ found that a vitamin C-free diet results in changes in the pulp and dentine molars. Hess,²⁴ however, considered that scurvy was not an important causal factor of dental caries which is present in marked degree where fruits and vegetables are in greatest abundance and least prevalent in countries, such as Alaska, where antiscorbutic foods are scarce. Hanke²⁵ and Harris²⁶ independently found that deficiency in vitamin C is a contributing cause of dental caries.

V. Oral Factors

Seven of the caries-susceptible children showed local factors that were determining in the causation of decay, while nine of the caries-immune group practiced such superb mouth care that it was considered primary in the maintenance of

dental health, all systemic factors being borderline with respect to dental structures. Two children ingested an excessive amount of sugar between meals with consequent acid formation, one massive amounts of acid fruit juices between meals and at bedtime with resultant recalcification revealing smooth yellowish surfaces from the minimal amounts of available salivary secretion, four showed complete lack of mouth care. Once these local conditions were corrected, dental caries was arrested within a month of the initiation of proper therapeutic procedures. Excessive ingestion of readily fermentable carbohydrate, especially sugar, favors the growth of acid-forming bacilli. But the presence of these organisms in the mouth alone is not sufficient to result in tooth decay. It must be in contact with certain areas of the tooth not cleansed by saliva, and the presence of sugars in the inaccessible areas of tooth surfaces provide the most favorable medium for the growth of the *BB acidophilus*. MacIntosh²⁷ has shown that lactobacilli tend to destroy teeth in the caries-susceptible but are absent in the mouths of those immune to caries. The oral flora is thus an important factor, for acid organisms decalcify regardless of the quality of the tooth structure. In most instances decay may be inhibited by decreasing the carbohydrate in the dietary. Boyd did not find that sugars are detrimental to teeth, nor did Schoental. But Bunting suggests a possible immunological factor antagonistic to the *B acidophilus* organism in the blood of the caries-free individual in whose mouths the *B acidophilus* does not exist, and when planted therein, promptly disappears.

Mouth fermentation can be readily prevented by diminishing the non-detergent carbohydrate such as soft bread, cake, cereal, malted milks, sticky foods, excessive sugars and starches both with and between meals. Stagnation of food can be prevented by the use of fibrous foods after each meal using raw fruit instead of sweet desserts.

Caries is preventable by choosing suitable food and thus keeping the teeth free from stagnant debris. Hoppert²⁸ demonstrated that the size of the food particles affected the incidence of caries and that a chemically adequate diet is no guaran-

tee against caries Klein and McCollum²⁰ found that coarse particles, lodged in crevices of the teeth, give rise to fermentation while the finely pulverized diet was readily washed away by the saliva Benst²⁰ showed that the self-cleansing properties in the mouths of children was preventive of caries It has been noted that fever patients are liable to an accumulation of sordes on the teeth due to the reduction of the flow of saliva with a consequent dry mouth Schnak²¹ cites a highly fermentable carbohydrate—Hawaiian food-stuff, poi, which is cohesive in the mouth and never clings to the teeth Hawaiian children have little dental caries It thus seems indisputable that sticky food of a fermentable nature clinging about the teeth and areas of stagnation is an important predisposing cause in the formation of caries It produces an acid tending to decalcify the enamel of teeth which are not immune to caries and lays them to attack by the exciting cause, the *B. acidophilus* organism

Proper masticatory stimulation is indispensable in the management of the child's oral hygiene Solid food should be introduced early in infancy to compel mastication, and the earlier the child is weaned from strained foods the better for the health of the teeth He should be taught to massage his teeth by chewing coarse food which favors secondary dentine deposit Breeze²² has demonstrated that trauma acts as an irritant to cause sclerosis of the teeth Coarse food scours tooth surfaces and the resistance to caries parallels the extent of sclerosis Nasal breathing should be maintained free in order to encourage proper chewing Food should not be washed down with milk but chewed, bread soaked in milk should be avoided

SULPHANILAMIDE

Report of a Case

JOSEPH MILLETT, B S, M D, *Hempstead*
Resident Physician, Meadowbrook Hospital

Pneumococcus Type 3, formerly called the Streptococcus Mucosus, has generally been recognized as producing lobar pneumonia of marked severity. The death rate for Type 3 pneumonia is much affected by age, and is the incidence of chronic systemic disease, whether occurring in the old or young. The death rate in patients under forty is approximately twenty per cent, over sixty years 65.4 per cent. In patients without systemic disease the death rate is 32.1 per cent, with systemic disease 53.6 per cent.¹ Cecil, Baldwin, and Larsen² found that Type 3 pneumonia ran, on an average, a somewhat longer course than either Type 1 or 2 infections.

There were eleven cases of Type 3 pneumonia (excluding the present reported case) seen at the Meadowbrook Hospital this past winter in adults. Seven lived and four died. Six cases were uncomplicated, while the seventh developed an empyema which came to rib resection. The longest stay in the hospital was ninety-six days, the case that came to surgery, while the shortest was eight days, the latter patient having been in bed at home two weeks before admission. The average stay for all seven cases was thirty-three hospital days, excluding the empyema the average stay for the uncomplicated cases was twenty-two days. This did not compare with our results in serum-treated, uncomplicated Type 1 (12 cases) cases treated this winter, whose average stay was eleven days, and the uncomplicated, non-serum treated Group 4 (10 cases) whose average stay was 10.5 days. (Group 4 cases were those who had pneumococci that showed no capsule swelling with 1, 2, 3, 5, 7 and 8 antisera.)

The following is a resume of the twelfth case of Type 3 pneumonia admitted to the Medical service late in April.

Case Report

F S., thirty-two year old white male, salesman by occupation, was admitted to the

Meadowbrook Hospital with the complaints of pain in the left chest aggravated on breathing, and cough with slight expectoration. He stated that about one week before admission he had a cold. Forty-eight hours before admission he had definite malaise accompanied by generalized aches and pains and felt feverish. The next day he vomited twice, had several severe shaking chills, began to cough and have pain in his left chest anteriorly. He was seen by his physician on the morning of the day of admission and hospitalization advised.

Past history revealed the usual childhood diseases, chorea, and a history of epigastric pain relieved by food and alkalis, and occasional tarry stools in the past two years. Appendectomy was done nine years ago.

Physical examination revealed a thin, undernourished white male, acutely ill, with lips and fingertips cyanotic. The temperature was 104.2 (R) P 120 R 32. The pharynx was acutely injected. There was a short, dry cough. Examination of the chest revealed impairment over the left upper lobe with bronchovesicular breathing. The rest of the examination was negative.

A blood culture was taken which proved to be negative. The urine concentrated well and showed a faint trace of albumin. The Hb was eighty per cent Sahli and the white count was 43,600, ninety-seven per cent of which were polys. The sputum showed many Type 3 organisms.

Clinical course The patient was put on sulphanilamide grams one (grains 15) q 3 h on the third day. The next morning there were signs of frank consolidation in the left upper lobe with bronchial breathing and whispered pectoriloquy. An x-ray taken at this time confirmed the diagnosis. Thirty-one hours after the institution of sulphanilamide therapy the temperature had dropped from 104.2 to 99.4 (R) after the administration of ten grams (150 grains) of the drug by mouth. For the next two days the temperature averaged 100 (R) and then dropped to normal. Sulphanilamide was continued until another fifteen grams (195 grains) had been given, a total of twenty-five grams in about 3½ days. (Chart I.)

The only untoward effect noted was a moderate cyanosis of the lips which persisted until discharge, on the morning of the tenth day.

than that which is offered, is significant in resistance to decay

5 Sixty-four percent of the children with caries were on suboptimal nutrition in contrast with sixty-six percent who were resistant to caries on the basis of satisfactory nutritional intake. The dietary deviations in carbohydrate, acid-base ash, calcium, and vitamins A, C, and D were corrected and the caries arrested within

three months in sixty-five percent of the children

6 Seven percent of the caries-susceptible children showed local factors causing decay while nine percent of those resistant to caries practiced excellent mouth care, systemic factors being borderline with respect to caries

OPIUM UNDER JAPANESE RULE

An important side-light on Japan's occupation of more and more Chinese territory is given in a recent report of the Opium Advisory Committee of the League of Nations, made before the present hostilities began. In the provinces now subject to Japanese influence the systematic increase of poppy cultivation and of the sale of opium is stated for the past year to have "attained alarming proportions." Illicit traffic in opium, morphine, and heroin is rapidly increasing in Manchuria and Jehol and is

encouraged as a fruitful source of revenue. It was estimated that 500 kilograms of heroin were exported each week from Tientsin and that ninety per cent thereof went to the United States. Canada also is suffering from this flow of narcotics from the Far East to the Pacific coast, and there has been no improvement during the last twelve months. The Advisory Committee recorded its alarm at the situation in the Chinese provinces under Japanese jurisdiction as constituting a real danger to the whole world.

The course of medical lectures for practicing physicians on diseases of the heart inaugurated last year proved so successful that the New York Heart Association of the New York Tuberculosis and Health Association has planned a second series during the fall and winter months. A series of twelve afternoon lectures will start November 9 and will be held at bi-weekly intervals up to and including April 26, 1938. The course is endorsed by the New York Academy of Medicine.

The course will be open to all practicing physicians without registration or admission

fee. The course is designed to give the general practitioner a better understanding of problems pertaining to the treatment of certain types of heart diseases. For the convenience of physicians residing outside of Manhattan, two of the lectures will be given in Brooklyn and one in the Bronx.

The first lecture will be on "The Management of Patients with Heart Disease" by Dr. Irving Roth on November 9 at 4:30 p.m. in the Mount Sinai Hospital, New York City. Other lectures in the course to be given by leading heart specialists will be announced later.

ganisms as well, and concluded that the degree of protection with one strain of meningococci (Type 2) was of the same order as with streptococci. Proom,³ working only on meningococcus infections of mice, found that the early administration of para-aminobenzenesulfonamide prevented the development of septicemia and death in animals so infected, and that it protected equally well against strains belonging to Groups I and II.

The only literature we have been able to find dealing with the treatment of meningococcus infections in human subjects with this drug, is the recent preliminary report of Schwentker, Gelman, and Long.⁴ These workers give a brief summary of their results in treating ten cases of meningococcus meningitis, and one of meningococcemia without meningitis. They conclude that the response to treatment was good in all patients, and quite comparable to that produced by specific antiserum.

It may be of interest therefore to report in detail two cases of meningococcemia successfully treated with sulfanilamide and its derivative prontosil. The first case is of special interest in as much as the patient had been ill with a high fever for more than seven weeks when this form of therapy was instituted. During this time he had three distinct episodes of meningitis, and had been treated with large amounts of meningococcus antitoxin and antiserum intravenously, intramuscularly, and intrathecally, without any apparent effect on the course of his blood stream infection. He had become extremely sensitive to both antitoxin and antiserum so that even the smallest amount of either given intravenously resulted in the severest kind of allergic reaction. He was in very poor condition in spite of three supportive blood transfusions, and it seemed inevitable that he would succumb to the malignancy of his infection. The prompt drop in temperature and almost immediate general improvement which ensued with sulfanilamide therapy is therefore all the more impressive. The second, a typical case of subacute meningococcemia without complications, would have been treated with large amounts of anti-meningococcus serum intravenously, but coming soon after our experience with the other, we were encouraged to try

sulfanilamide and again with spectacular success.

Case Reports

CASE 1 W. W., a white male, aged thirty-seven, a foreman in the Department of Sanitation, was admitted to Morrisania City Hospital on January 10, 1937, complaining of chills and fever of six days duration. His past history was as follows. He had pneumonia in 1922, an appendectomy followed by pneumonia in 1924, and scarlet fever in 1935. Six days before admission he awoke in the morning with chills, followed by fever, and a temperature of 104°F. He did not have a cold, or any upper respiratory symptoms, prior to, or at the time of onset. He did recall having noticed a red "spot" on his right forearm, similar in appearance to the generalized eruption he later developed, the day before. The day following onset all his symptoms disappeared and he felt quite well. Three days before admission the fever and chills returned, this time accompanied by pain in the lower extremities. On the day of admission he complained of a severe headache and vomited, a rash appeared over his trunk and extremities. Then he became unconscious.

Physical examination disclosed a well-developed and well-nourished white male, acutely ill, semicomatose, perspiring profusely, with a temperature of 105°. The nose and throat were normal. His pupils were equal and regular, and reacted well to light and accommodation. There were no ocular palsies. The neck was rigid. The lungs were clear. The heart was not enlarged, there were no thrills or murmurs. His blood pressure was 114/74. The spleen and liver were not palpable. The Kernig and Brudzinski signs were positive bilaterally, and the knee jerks and ankle jerks diminished. There were petechiae and hemorrhagic maculopapular lesions scattered over the trunk and extremities.

Laboratory findings. The urine was normal except for a faint trace of albumin. The blood count showed 4.14 million erythrocytes, with a hemoglobin of ninety per cent, 14,600 leukocytes, with a differential of seventy-eight per cent polymorphonuclears and four per cent stab forms. Chemical examination of the blood showed a sugar of ninety, and urea N of 16. Blood Wassermann and Kahn tests were negative.

Spinal puncture was performed immediately, and twenty-five c.c. turbid yellow fluid, under an initial pressure of twenty-five cm. of water, removed. Examination of this fluid showed the globulin to be increased and sugar absent. There were 3,400 cells per cmm, all polymorphonuclear leukocytes. A smear revealed the presence of oc-

Discussion

At the present time there is no specific horse serum available for Type 3 pneumonia. Immunity against Type 3 pneumococcus is difficult to acquire either by artificial or natural methods.^{3,5} Convalescent serum has been tried,⁶ as has transfusion with blood from donors who had been immunized against pneumococcus Type 3.⁷ The use of an enzyme (enzyme of Avery)^{8,9} which destroys the specific carbohydrate in the capsule of the Type 3 pneumococcus has shown distinctly curative properties in experimental animals.

Domagk¹⁰ first introduced para-aminobenzene sulfonamide and its derivatives as chemotherapeutic agents against the hemolytic streptococci with marked success. Buttle et al.¹¹ studied the effects of para-aminobenzene sulphonamide on Types 1 and 2 pneumococcal infections in mice without any marked results except to delay their death by a few days. Rosenthal,¹² however, found that sulphanilamide had distinctly curative effects on mice in-

noculated with Types 1, 2, and 3 and that it was bactericidal and bacteriostatic to pneumococci type 1, 2, and 3 in high dilutions *in vitro*.¹³

The exact mechanism of the action of sulphanilamide against the pneumococcus is unknown. That it attacks the capsule of pneumococcus is the most likely possibility. The literature on experimental and clinical data concerning the action of these compounds in pneumonia is at present very meager, but most likely will not remain so. In view of the general experience with type 3 pneumonia, and the lack of a specific means of attacking this disease, it would be well worth while to use these apparently nontoxic organic compounds.

Summary

A case of Type 3 pneumococcus pneumonia, involving one lobe, and only twenty-four hours after onset, is presented after having a crisis induced by sulphanilamide given by mouth. It is recommended that the drug be given an extensive clinical trial in Type 3 pneumonia.

MENINGOCOCCEMIA

Treatment with Sulfanilamide and Prontosil—Report of Two Cases

J. F. ZENDEL, M.D. and DAVID GREENBERG, M.D., New York City

From the Medical Service of Morrisania City Hospital, Dr. Edward Flood, Director

Chemotherapy in the treatment of bacterial infections received a new impetus when Domagk,¹ in 1935, described the efficacy of prontosil, a derivative of sulfanilamide (para-aminobenzenesulfon-

amide), in protecting mice against infection with hemolytic streptococci of human origin. Buttle, Gray, and Stephenson² in confirming this work, experimented with this therapeutic effect on other or-

palpable. The knees and ankles were tender and slightly swollen but not red or hot to the touch. The Kernig and Brudzinski signs were both absent. Soon after admission, the house physician noticed and brought to the patient's attention a rash of which he was not aware. This consisted of a maculopapular eruption, slightly tender to the touch, scattered over the chest and all the extremities.

Laboratory findings The urine was normal except for a trace of albumin. The blood count showed 18,500 leukocytes, seventy-seven per cent of which were polymorphonuclears. Hemoglobin was eighty-five per cent. Chemical examination of the blood revealed eighty-five mg of sugar per 100 c.c., and a urea N of 17. Wassermann and Kahn blood tests were both negative. An electrocardiogram revealed no abnormality. Blood cultures taken on March 17 and 19 were both reported positive for the meningococcus. The organism was further classified as a Group III meningococcus by the Meningitis Division of the New York City Health Department.

Course The patient ran a septic temperature for eight days, his general condition remaining unchanged. At no time did he show any signs or symptoms of meningitis, so no spinal tap was done.

On March 20 treatment was begun with sulfanilamide and protosil. During the next forty-eight hours he received 5.2 grams (80 grains) of sulfanilamide, and 100 c.c. of protosil. During the succeeding six days he received 0.65 grams (10 grains) of sulfanilamide three times a day. Approximately sixty hours after the onset of treatment, the temperature fell abruptly to normal and remained so for the rest of his stay in the hospital. Subjective improvement began promptly with the subsidence of temperature. No new skin lesions were observed following the first twenty-four hours of treatment, and the arthralgias disappeared permanently and completely at the same time. A blood culture taken then was reported negative.

Comment

In view of the small number of reported cases of meningococcus infections treated successfully with sulfanilamide, it is much too early to reach any definite conclusions as to the therapeutic merits of the drug in such conditions. Furthermore, nothing as yet is known of the possibility of delayed toxic effects following its administration. Immediate complications, occurring during the course of treatment, such as cyanosis, nausea,

acidosis, dyspnea, and morbilliform eruption have been described, but these have all promptly cleared with cessation of therapy. Our own two cases showed no ill effect from the drug during its administration and the following period of observation. From the results thus far obtained, it would seem that sulfanilamide in the treatment of meningococcus infections is worthy of further trial in well-controlled clinics. Certainly, it appears to be indicated in cases of prolonged meningococcic septicemia, which have become sensitized to all forms of serum therapy, rendering further treatment with this medium impossible, as occurred in Case 1. Should future experience with sulfanilamide prove it harmless, and of consistent value in treating infections caused by the meningococcus, its superiority to the present mode of therapy with antiserum and antitoxin will be manifest. In the first place, even cases treated successfully with antiserum and antitoxin frequently develop severe serum sickness during or soon after treatment. Thus, recently, a case of uncomplicated meningococcemia, very similar in its course to Case 2, was treated on this service by the administration of 150 c.c. of meningococcus antiserum on two consecutive days. The serum was given by slow intravenous infusion, well-diluted with normal saline. On the third day, the patient developed a terrific serum reaction with giant urticaria, extremely painful joints, generalized adenopathy and a temperature ranging above 104° . This persisted for an entire week although no further serum was given. At the end of that time the blood culture was sterile and the patient convalescent. However he had been far sicker with the serum reaction than with his original illness. Secondly, the risk of sensitizing the patient to future administration of horse serum is obviated, a distinct advantage when one considers the multiplicity of purposes for which such sera are employed today.

Still another advantage is the promptness and completeness of the therapeutic response, at least as evinced by our cases. Meningococcemia is a disease notorious for the frequency and seriousness of its complications, which include meningitis, endocarditis and arthritis. Appelbaum³ recently reported on a series of fifteen

casional intra- and extracellular Gram negative diplococci

Course Treatment was begun immediately with meningococcus antitoxin intrathecally and intravenously. Two days later, (January 12) the patient developed a serum rash, but treatment was continued without interruption. Three days later, a spinal tap was reported as clear and having only fifteen cells to the cu mm, sugar was absent. His high temperature continued unabated, however, and his general condition was unimproved. On January 17 he developed a very severe serum reaction. His body was covered with huge wheals and his face was swollen. He vomited and complained of dimness of vision. Examination of his fundi revealed blurring of the optic disks. Spinal tap that day, however, showed the fluid to be still clear and with only sixteen cells, although sugar was absent. Because of these findings, his signs and symptoms were believed due to edema of the brain brought on by the violence of his allergic reaction, rather than to a recrudescence of his meningitis.

On January 18, and again two days later the blood culture was reported positive for the meningococcus. To combat the septicemia (on the latter date), intravenous therapy with antitoxin was again attempted. The antitoxin was administered by slow intravenous infusion, well-diluted by saline. When only 15,000 units had been administered, the patient developed a terrific serum reaction, with a severe chill and giant urticaria, and treatment had to be stopped.

At this point, antiserum was substituted for antitoxin. The results were disappointing, for he proved to be just as sensitive to the antiserum as he had been to the antitoxin. On January 25 he was given a blood transfusion of 350 c.c. in an effort to improve his general condition, which was quite poor by this time.

Two days later, he again developed symptoms of meningitis, and spinal tap done that day showed the presence of a cloudy fluid with a pressure of thirty-two cm. of water, 22,000 cells, and a few Gram negative diplococci. The meningitis was treated with antiserum intrathecally, which he tolerated fairly well, and the spinal fluid cleared up in a week. The blood culture remained positive, the temperature high, and the patient as sick as ever. On February 1, he received a second blood transfusion of 250 c.c., and the third, also of 250 c.c. eight days later. On February 15, he again developed signs of meningitis, and his spinal fluid was cloudy, with 2000 cells to the cu mm. This cleared rapidly, but the blood culture re-

mained positive. During this entire period, several careful attempts at desensitization were made, but the result was always the same. As soon as the amount of serum injected reached three or four c.c., the patient promptly developed a most alarming allergic reaction.

It was realized that further attempts at serum therapy were futile, and Dr. Josephine Neal of the New York City Health Department was consulted for the purpose of preparing an autogenous vaccine. At her suggestion it was decided to try sulfanilamide therapy first.

Treatment was begun on February 24, and during the next 48 hours he received forty c.c. of prontosil, and 8.45 grams (130 grains) of sulfanilamide, in divided doses, at intervals of four hours. For the next three days he received sulfanilamide alone, 0.65 grams (10 grains) three times a day. At the end of the first forty-eight hours of treatment, the temperature fell to normal, and remained so until the patient's discharge twenty-three days later. His general condition began to improve immediately, and he had a rapid and uneventful convalescence without any further treatment. Two blood cultures taken after the temperature had returned to normal were reported negative.

CASE 2 F. K., a white male, aged twenty-seven, an unemployed furrier, was admitted March 12, 1937, complaining of fever and malaise of two weeks duration, and pain, swelling, and redness of both knees and ankles for one week. His family history was negative. He had never been sick before with anything more serious than a cold. He specifically denied ever having had rheumatic fever. His present illness had begun with a feeling of lassitude and chilly sensations. He did not have a cold or any symptoms referable to the upper respiratory tract. These symptoms persisted for a week, when he began to have in addition pain in both ankles, which became swollen. This soon spread to involve both knees, and the small joints of his hands and fingers. All these joints were involved at the time of admission.

Physical examination revealed a well-developed and moderately well-nourished white male, acutely ill, with a temperature of 101.6°. His pupils were equal and reacted well to light and accommodation. The pharynx and soft palate were intensely injected, the tongue coated but moist. His neck was not rigid. The lungs were clear. The heart was not enlarged and the sounds were of good quality. There were no murmurs or thrills. The blood pressure was 120/70. Abdominal examination was negative, the liver and spleen not being

immense multiplication of the organisms. When one loopful of the organism was given each of six mice two or even three mice would survive. The two loopfuls were therefore used throughout the study for infecting the mice. One hundred per cent of deaths were always obtained in the control mice. Since the organism is so highly invasive (it can be recovered from the heart's blood a few hours after infection), Prontosil* solution was selected for this work because it is rapidly absorbed into the system. It is excreted through the urine very soon after injection. The work embraced the following experiments (Tables I-II).

1 Mice were injected intraperitoneally with two loopfuls of the culture. A 25% solution of Prontosil in different dosage was injected subcutaneously after infection and repeated again three to four hours later. If they lived until the next day, more Prontosil was given.

2 Two loopfuls of the culture emulsified in one c.c. of immune influenzae meningitis serum (agglutinating titer from 125,000 to 140,000) were injected intraperitoneally into the mice. Three to four hours later the same serum was given to one group of animals intraperitoneally and to the other subcutaneously. If they lived, more immune serum was given the next day.

3 Two loopfuls of the culture emulsified in one c.c. of normal horse's serum, containing the same preservative as the immune serum, were injected intraperitoneally as described above for the immune sera. The same serum was injected three to four hours later in one group subcutaneously and in the other intraperitoneally.

These three modes of experiments failed to lead to any satisfactory results. The treatment with Prontosil given in small dosage as used by Domagk (1/10 of the tolerant dose) or the rather large dose used by Long and Bliss (one gram per kilogram) gave erratic results. The most it did was to prolong for some hours the life of some mice beyond the twenty-four hours, or sometimes it saved one out of six, once it saved two out of six. The treatment with immune serum alone led to about the same results as the treatment with Prontosil solution alone.

*We are indebted to Winthrop Chemical Co. for supplying us with the Prontosil 25% solution for this work.

The mice treated with the normal serum died at the same time as the controls, thus proving that the preservative employed both in the immune and normal serum had no effect on the organism. The cultures were recovered from the heart's blood and peritoneal fluid of the mice which died after these three modes of treatment. In a few cases of treatment with immune serum, however, we failed to get the cultures from the heart's blood even though it was recovered from the

TABLE I—EFFECT OF PRONTOSIL ALONE

No. Mice	Initial treatment	Total treatments	Death in days			Mortality %

peritoneal fluid. We could assume from this fact that the immune serum may sometimes stop the invasion of the organism. It then occurred to the author to treat the infected mice with a combination of immune serum and Prontosil. From the clinical experience of different workers, such as Neal, Fothergil, Ward, and others, it was found that the immune serum lacked something in its constitution

cases observed by him, and of this number only three remained uncomplicated during their entire course. Should sulfanilamide with further use prove fairly consistent in thus cutting short the disease before complications have time to manifest themselves, its superiority in this respect alone will mark it as an advance over previous forms of therapy.

It is interesting to note that in both cases the temperature dropped to normal and improvement commenced between the second and third day following onset of treatment. Marshall, Emerson, and Cutting,⁶ who recently reported on the absorption, blood concentration, and excretion of sulfanilamide in animal and human subjects, found that in administering a given daily amount of the drug in divided doses it took from two to three days to establish equilibrium between the amount ingested and the amount excreted. Concentrations of between 1:5000 and 1:10-

000 were thus obtained and maintained in the blood stream. Once this equilibrium was established, they were frequently able to account for almost one hundred per cent of the daily dose ingested by the total excretion of sulfanilamide in free and conjugated form in the urine. It is striking that both therapeutic responses occurred abruptly at the time, when according to the findings of Marshall and his coworkers,⁶ it might be surmised that a maximum concentration of the sulfanilamide in the blood had been attained.

Summary

Two cases of meningococcemia, one complicated by three episodes of meningitis, the other uncomplicated, were treated successfully with sulfanilamide and its derivative prontosil.

150 E. 40 St.
1882 GRAND CONCOURSE

The prontosil referred to in this article is not the original prontosil as used by Domagk, but the product put out by the Winthrop Chemical Co. under that name. It is a 25 per cent solution of the red dye, the disodium salt of 4-sulfamido-phenyl-2'-azo-7'-acetylamino-1'-hydroxynaphthalene-3,6'-disulfonic acid, which is referred to in the European literature as Prontosil Soluble (prontosil S) and Streptozone S.

IMMUNE SERUM AND PRONTOSIL

Combined Treatment for Protection of the Mouse against Fatal dose of Hemophilus Influenzae Meningitis—Preliminary Report

OLGA R. POVITZKY, M.D., DR. P.H., New York City

From the Research Laboratories, New York City Department of Health

The recent favorable results reported by different authors in treatment of hemolytic streptococcal infection with prontosil, prontosil, and other sulphanilamide compounds, led the author to try the drug in mice infected with a culture of *H. influenzae*, recently isolated from spinal meningitis. Previous work on the infectivity of *H. influenzae* meningitis cultures in guinea pigs had always proved unsatisfactory. The reason for this is that no matter how virulent the culture is for this animal immediately after isolation, it loses its virulence rapidly even when treated with mucin according to

Miller's method for meningococcus. A preliminary study of the infectivity of this organism in mice was therefore made to insure the minimum fatal dose before studying the effect on it of the drug. It was found that two standardized loops* of the organism emulsified in one c.c. of salt injected intraperitoneally invariably killed mice weighing from eighteen to twenty grams in from eighteen to twenty four hours. On autopsy, the culture was recovered from the heart's blood and peritoneal fluid. The latter showed an

*1 loop approximately 2x4 mm including wire

RADIATION PLEUROPNEUMONITIS

LOUIS NATHANSON, M D, M Sc (Med), *Brooklyn*

Radiation pleuropneumonitis is an entity that is becoming more prevalent with the wider use of recent methods of radiation therapy applied to the chest wall. With the protracted fractionated method of x-ray therapy, massive dosage may be applied to the chest wall with less skin effect and considerable increase in the quantity of radiation reaching the underlying intrathoracic structures. As a result of this, changes are developing in the lung and pleura with increasing frequency.

These pulmonary changes were first described by Christie and his coworkers¹ in 1922, and since then several papers dealing with this subject have appeared in the literature. It is interesting to note, however, that since the widespread use of massive dosages of x-ray therapy in both pre- and postoperative breast malignancy, the instances of radiation pleuropneumonitis have probably increased without being commented upon or not recognized as such.

This complication developed in three instances in my own practice in a series of forty five patients, and in each of the three patients where other opinions and consultations were sought, the diagnosis of metastatic malignancy, tuberculosis, etc. were suggested and a poor prognosis given.

Although it is generally known that radiation when applied to the chest wall may produce a slight degree of underlying pulmonary fibrosis and pleural thickening, it is not well-known and even denied by many, that pulmonary pneumonitis and pleurisy with effusion may result. When this complication does develop, it is almost invariably considered due to metastatic disease, and only those familiar with this entity which Christie and his coworkers rightly termed Radiation Pleuropneumonitis recognize the benign character of the lesion. Since this complication is occurring with greater frequency, it should be reported so that the profession at large may become familiar with it and not misinterpret its significance both as to the prognosis and treatment of the patient.

Case Reports

CASE 1 A female forty two years of age had a radical mastectomy performed for what proved to be an adenocarcinoma of the right breast with axillary metastases. Three weeks after the surgical procedure she was referred for postoperative x-ray therapy. Six portals of entry were used to include the breast region and the surrounding gland bearing areas—two tangential ports were used directly to the chest wall corresponding to the breast region, three to the axilla one anteriorly, one posteriorly, and a third directly into the axilla, and a sixth port to the supraclavicular region. 1800r units of radiation was applied to each of the six ports, using 300r daily and treating one area at a time with the following factors 200 KV, $\frac{1}{2}$ Cu and 1 Al filtration, at fifty cm distance delivered at the rate of 111r per minute. This therapy was applied over a period of six weeks.

Aside from a slight degree of radiation sickness, the patient showed no ill effects during the course of therapy. Three weeks later, however, she developed a chronic non-productive cough with dyspnea on exertion, pain on the right side with breathing, and a temperature which ranged from 99 to 101°F. Although the above symptoms were present, she was not acutely ill and if it had not been for the temperature she would not have been confined to bed. Roentgen examination at this time, (Fig 2) showed an extensive infiltration of a coalescent type resembling an exudative productive lesion and occupying the middle third of the right lung field. A slight haze was present over the infraclavicular area. The right cusp of the diaphragm was elevated and peaked mesally and the mediastinum retracted moderately toward the affected side. There was a generalized curvature of the spine with the concavity toward the affected side which suggested a splinting of this side of the thorax. On comparing this x-ray study with the one made prior to the onset of radiation therapy (Fig 1) one notes that the lung fields were entirely clear and that the above changes had developed since the onset of treatment.

The patient remained in bed three weeks and at no time was acutely ill. Her symptoms—temperature and evidence of infiltration—rapidly subsided and a further roent-

to give the favorable results which may theoretically be expected of it. The fact that so many patients improve at once after administration of the serum only to die of a relapse some time later, leads to all sorts of speculations as to what factor this serum was lacking. Fothergill, Chandler, and Dingle¹ suggest in their latest publication that H influenzae may be protected from the destructive action of antiserum when ingested and walled off by phagocytes. Perhaps Prontosil helps the serum to penetrate this wall. In the case of mice at least, it would seem that the agent to accomplish this may prove to be Prontosil. The experiments were conducted in the following manner (Table III)

1 Mice were injected with two standardized loopfuls emulsified in one cc of salt solution and injected intraperitoneally. All six died the next morning.

2 The fatal dose was emulsified in one cc of immune serum and injected intraperitoneally. 0.3 cc. Prontosil of 2.5% solution was given immediately subcutaneously. Three hours later, 0.3 cc of Prontosil was again given subcutaneously. The next morning 0.7 cc of immune serum and 0.3 cc of Prontosil was given subcutaneously. If the mice did not look particularly lively, another dose of 0.3 cc Prontosil was given subcutaneously. Those which survived the second day remained alive indefinitely. With this treatment, four to five of a series of six mice injected survived.

3 This experiment was the same as experiment #2 except that three hours after initial injection, 0.7 cc of immune serum was given subcutaneously in conjunction with the 0.3 cc of Prontosil (2.5% solution). In these series of six mice, there were from four-six mice surviving.

In order to make sure that the infective dose is the same for all mice, the following procedure was carried out. The cultures were grown on chocolate medium in potato tubes (5½ in long, ¾ in wide) for twenty-four hours. Six loopfuls of the culture of such a tube were used for infecting three mice. If, say, thirty-six mice were to be injected, we used twelve tubes, six loopfuls from each, and the seventy-two loopfuls of the organisms emulsified homogeneously in salt solution and then enough salt solution added to

make 0.5 cc of this emulsion the infective dose. The 0.5 cc of this emulsion was then added to one cc of salt for each of the six mice for controls and 0.5 cc of the emulsion to one cc. of immune serum for each of the six mice used in experiments #2 and #3.

Identical results were obtained with this more accurate method as in the one where two standardized loopfuls were emulsified directly into the serum. There were from four-six survivals in each of the series of six mice, except, of course, in the controls where death occurred in one hundred per cent of the animals overnight. When the immune serum plus Prontosil were given three hours after the fatal infection, all mice were dead the next day. Perhaps the infective dose is too severe for a delayed treatment to be of help. Neither was the Prontosil plus serum effective when the initial dose of the serum was given subcutaneously instead of intraperitoneally. Although the immune serum should be given for the initial dose intraperitoneally in contact with the organism, the mice do better if the subsequent treatment with the serum is given subcutaneously. Mice as a rule cannot stand too heroic treatment. They did not do well when we tried to give three treatments a day instead of two.

We are therefore led to believe, as a result of our experiments, that Prontosil may prove the needed adjunct to immune serum in the influenzae meningitis clinical cases, when the infection is not too overwhelming. At the end of this study an article appeared written by Branham and Rosenthal² on the use of combined sulphanilamide and immune serum in treatment of meningococcus and pneumococcus infection in mice. These authors also feel that the drug may be a good adjunct to the serum treatment of these infections.

therapy to the breast after a local surgical excision of a tumor which proved to be a colloid malignancy without palpable metastases. She received a course of radiation therapy consisting of 1800r units applied to each of six areas as in the previous case.

Four weeks after the completion of treatment, she developed a marked hacking unproductive cough, a general feeling of

Fig 5

Fig 6

Fig 8

malaise and ran a slight temperature. Signs of infiltration appeared in the underlying lung. Roentgen studies two weeks after her symptoms and temperature had almost completely subsided showed (Fig 5) a coalescent infiltration very similar to Case 1 involving the middle third of the right lung held with surrounding patchy areas in the adjacent portions of the lung. The cusp of the diaphragm was raised and there

Fig 1

Fig 2

gen study made three months later (Fig 3) revealed some evidence of fibrosis in the upper lobe, some mediastinal retraction, and elevation of the diaphragm. The infiltration had entirely resolved. Her general condition throughout was excellent. The subsequent course was uneventful aside from an occasional sticking sensation in the right chest and an infrequent, slight, unproductive cough. She gained weight rapidly and there has been no recurrence of her breast

pathology. Over a period of eighteen months, since the above episode and almost two years after her mastectomy, this patient has remained perfectly well. Roentgen study at this time (Fig 4) showed slight residual fibrosis and some elevation of the diaphragm which was freely movable. The mediastinum was retracted.

CASE 2 A female, fifty-one years of age, was referred for postoperative radiation

Fig 3

Fig 4

Fig 11

The amount of radiation therapy given varied. In the third case, 1200r was administered to each of four areas and in Cases 1 and 2, 1800r was administered to each of six areas. In the patient receiving the least amount of radiation, the reaction on the skin as well as in the lung developed during the course of radiation therapy, and for this reason, the therapy was stopped. In Cases 1 and 2, symptoms developed three and four weeks later and in neither case was there more than a first degree reaction on the skin nor evidence of severe radiation sickness. The patient receiving the least amount of therapy volunteered the information that she vomited readily on the least provocation and was of a very neurotic temperament. It was very difficult to evaluate her symptoms in relation to the radiation therapy.

This observation corresponds with the experimental evidence that Davis² was able to obtain. He states that there was the greatest variance in the amount of radiation used to produce these intrathoracic changes. In his experimental animals, only 120 ma minutes were required in one case and in another, 730 before developing symptoms referable to the chest. As described in the first two cases, six portals of irradiation were used in all of the forty five cases from which this series was taken except in the one instance where only four portals of entry

were used. These areas were divided as follows: two to the breast area, one left and one right using tangential radiation as much as possible, the third area directly to the supraclavicular region, and three to the axilla, cross-firing this area, using one anterior and one posterior port, and a third directly to the axilla. The posterior port to the axilla was extended to include the posterior shoulder girdle region and the supraclavicular region posteriorly. One area was treated daily giving 300r units per treatment and using the following factors: 200 KV, four ma, fifty cm Std and one-half Cu plus one Al filtration. A first degree reaction was obtained in nearly every instance. No skin sequelae, except a faint tanning, resulted after the erythematous reaction subsided.

In making a differential diagnosis, several possibilities must be considered—metastatic malignancy, pulmonary tuberculosis and a nonspecific infectious pneumonitis. The appearance of the lesion is not characteristic of malignancy. It resembles more a pneumonic process of the exudative productive type of tuberculosis described by Ornstein and his coworkers. Repeated sputum examinations proved to be negative, and as previously stated, the studies made prior to the irradiation in each instance showed the lung to be entirely clear so that the possibility of light-

Fig 12

was a curvature of the spine with the concavity to the right. These changes had developed since the radiation therapy was completed, since a fluoroscopic study immediately after completion of therapy revealed the underlying lung to be clear. Restudy, five weeks later, (Fig 6) showed that a collection of fluid had developed at the right base. The infiltration had cleared somewhat. Studies made two and three months after the first examination and three and four months after the completion of therapy, showed gradual resolution of the exudate and the clearing of the pleural effusion with an irregularly elevated and peaked cusp of the diaphragm (Fig 7). During this interval, the patient's symptoms gradually subsided leaving only a slight throat irritation coming on at irregular intervals. Fig 8 shows the condition of the lung fifteen months later. There is a slight residual fibrosis in the upper lobe and the diaphragm though somewhat raised is more smooth and regular. The curvature of the spine has been overcome.

CASE 3 A white female, age forty-eight was referred for postoperative radiation therapy after a radical mastectomy of the right breast. The pathological report was adenocarcinoma with axillary metastases. Deep radiation therapy was given at daily intervals using the same factors and setup as in the previous two cases. This patient stood her treatments badly and it was necessary to prolong the intervals and decrease the quantity of radiation at each treatment. She received 1200r units to each of four

Fig 10

areas—two to the breast region, one directly to the axilla, and one to the supraclavicular region. She developed a rapid first degree reaction on her skin and a concomitant pulmonary infiltration (Fig 9) before the therapy outlined for her was completed. The infiltration, unlike in Cases 1 and 2 was of a diffuse, patchy type scattered throughout the entire lung. The diaphragm was elevated and there was some retraction of the mediastinum. These changes had developed entirely since the onset of therapy, as a previous fluoroscopic examination was negative. The only symptom during this time was a persistent unproductive hacking cough. Three and a half months later, a restudy of the chest showed considerable clearing of the exudate (Fig 10). Five months later or nine months after the completion of treatment, there was still an irregular, patchy infiltration and fibrosis throughout the right lung with the same elevation of the diaphragm. There was a marked retraction of the mediastinum posteriorly with emphysema of both the upper and lower lobes apparently compensatory in nature to the fibrosis present. This patient is now free of symptoms referable to the chest aside from a slight infrequent unproductive cough.

All three patients aside from the local malignant process, showed no other evidence of disease. All three were in the fourth and fifth decades of life. The arteriosclerotic changes stressed by McIntosh⁵ were not present in these patients.

MECHANICAL RESUSCITATION OF THE NEW BORN

According to D Ben Martinez, Pittsburgh (Journal A M A, Aug 14, 1937), the problem of a safe and sane method for the resuscitation of the newborn requires serious thought at the present time, owing to the fact that each day more women demand the use of various drugs to make "childbirth painless," with the natural sequela that the obstetrician has to deal with more narcotized babies.

This demand, as the obstetrician knows, is due to the unfortunate publicity given in the lay press about their uses. The staff at Magee Hospital has gone through the various stages in the development of resuscitation of the new-born, i.e., the old mouth to mouth method, the hot and cold tubbing, various forms of manual methods, and the use of oxygen or oxygen-carbon dioxide mixtures held over the baby's face by means of a funnel or a catheter placed down in the baby's larynx for it to receive the gas in a concentrated form. In 1930 the author imported a von Wachenfeldt respirator from Sweden.

This chamber type of apparatus, in which a definite (15 mm) positive and negative pressure is exerted on the baby's body with the head remaining outside the cabinet so that oxygen can be given directly to the fetus, seemed to be an improvement over previous methods.

However, since July 20, 1934, the E & J Resuscitator has been used at the Magee Hospital.

It is a positive and negative apparatus and the pressure is exerted by the oxygen over the baby's face through a mask similar to that used in administering gas anesthesia. The apparatus is equipped with two tanks—one of oxygen and the other a mixture of ninety per cent oxygen and ten per cent carbon dioxide, so that either can be used with ease. The reversal of positive pressure to negative pressure and vice versa is brought about by a tripping mechanism which operates when the intrapulmonary pressure of the patient's

lungs reaches either the predetermined positive or negative pressure.

This principle of operation enables the apparatus to adjust itself automatically to the proper volume and respiratory rate of any size lung regardless of how small or how large.

A very rapid tripping due to the diminished capacity, warns the operator when the airway is obstructed by mucus, the tongue or some foreign substance.

When spontaneous respiration has been established the respiratory efforts of the patient cause the sensitive mechanism to respond by tripping rapidly or irregularly.

At this stage the operator turns a lever and the apparatus is immediately changed from a mechanical resuscitator to a simple inhalator.

On the basis of observations on 500 cases, in all the obstetric services of the Magee Hospital in which the E & J Resuscitator was used the author concludes that this mechanical positive and negative pressure apparatus is a definite improvement over any other method, not only in resuscitating the babies that actually need it but also in aiding the babies that just do not cry vigorously.

The safety of this apparatus is certainly an important factor since any one (nurse or intern) with a little training can use it thereby permitting the obstetrician to devote his full attention to the mother when needed, as is very often the case in difficult deliveries in which asphyxia is apt to occur.

The resuscitator is almost fool proof, as the positive and negative pressures cease automatically when the child breathes of its own accord and allows it to breathe the oxygen from the bag, or, if desired, it may breathe the oxygen-carbon dioxide mixture through the inhalator attachment. The author believes that this is a definite lifesaving device and should be a part of the armamentarium of all hospitals that have obstetric patients.

ing-up of a previously inactive tuberculous lesion, is rather remote. The spontaneous clearing of the lesion rules against malignancy, and in all three cases followed—two years, two years, and two and a half years,—no recurrence in the lung has developed. A nonspecific pneumonitis developing in the area of diminished resistance following irradiation cannot be ruled out entirely. However, the occurrence of the lesion directly in the path of radiation and the increased frequency of this occurrence with the quantitative increase in the radiation administered, and the indisputable experimental evidence obtained by Davis² seems to prove that we are dealing with a definite entity.

Obviously very little pathological material is obtainable since these patients do not succumb to this pulmonary lesion. We have, however, excellent experimental evidence obtained by Davis, which establishes this finding as a definite pathological entity. He states that the lesion can be produced at will on experimental animals. Davis found that the experimental pathological picture at the onset is that of a marked edema and congestion of the lung followed by cellular proliferation, especially in the alveolar walls. The majority of cells probably are connective tissue cells. He feels that fibrosis undoubtedly plays a part in the latter stages but that atelectasis cannot be ruled out. He was able to produce a pleurisy with effusion in one instance. McIntosh cites one case in which she was able to obtain pathological evidence of the changes produced by radiation. This patient died of a lobar pneumonia involving the opposite lung. The lung affected by radiation in this instance was covered by a thick, yellowish green, fibrinopurulent exudate. The cross section revealed a firm consolidated surface. The pleura was thickened and the entire upper lobe was involved in a peculiar consolidation consisting of dense patchy white areas many of which were in close relation to the smaller bronchi. Definite peribronchial fibrosis was present throughout. Histologically there was intense thickening of the alveolar wall with some exfoliation of the lining cells into the lumen. Perivascular and peribronchial thickening were present in all sections.

Coryllos⁴ feels that atelectasis secondary to bronchial obstruction explains the pathological picture. Massive radiation in his opinion produces a marked edema and swelling of the bronchial mucous membrane causing obstruction. Adair⁵ has shown that the occurrence becomes more frequent with the increase in the amount of radiation used, and he was able to produce this change almost at will when the amount of radiation was increased above 1800r units of radiation per portal.

Leucutia and Evans⁷ have been able to develop pulmonary changes with stated percentages of radiation applied to the chest wall. The roentgen findings—the elevated diaphragm, retracted mediastinum, and narrowed interspaces—are strongly suggestive of atelectasis, and the lung changes can readily be explained in this manner.

These experimental studies point to a quantitative physical basis for the development of the pathology, and as such, favor atelectasis. Although this may not explain the entire picture, it probably plays a major part.

As stated previously, this complication occurred in three in a series of forty five cases treated by massive radiation to the chest wall. The complication should not be considered a contraindication to therapy of this type since the results in the treatment of breast malignancy, as far as we can judge at the present time, have been improved by this method of therapy. The morbidity is slight and when followed over a period of time, the lung findings cleared almost completely leaving only a slight residual fibrosis which causes very little if any embarrassment to the patient. In many instances, the condition is not recognized, because routine studies of the chest are not made during and immediately after the roentgen therapy is given. In some instances, the symptoms may be absent entirely. As a rule, symptoms develop a month or so after the completion of radiation and correspond to the height of reaction on the skin.

The importance of the subject lies in not misinterpreting the lung pathology as being due to metastatic disease, tuberculous or other serious pulmonary pathology but rather a transient pneumonitis.

RADIATION PLEURO-PNEUMONITIS

October 12, 1937]

which will clear, producing very few subsequent ill-effects. Once the condition is recognized as radiation pleuropneumonitis, the benignity of the lesion becomes evident and the prognosis as well as the treatment of the patient can be properly controlled.

CANCER OF THE BREAST

Present Status of Surgery and Irradiation Therapy

FRANK E. ADAIR, M.D., *New York City*

Attending Surgeon Memorial Hospital

Irradiation therapy has made enormous strides particularly within the past ten years due to two reasons. The first was the introduction of high and super-voltage x-ray equipment, so that more effective irradiation can be given in the depths of the tissues. The second advance was made by Coutard, of Paris, who introduced a new principle in the technical application of the x-ray dose. Coutard, instead of giving the massive doses which so commonly result in nausea and radiation sickness, divided the doses into smaller units, not only relieving the patient of so much radiation sickness, but also resulting in being able to give much greater and more effective doses. The second step, namely the fractionating of doses, opened up entirely new vistas in radiation therapy in general. A few types of cancer heretofore treated best by surgery or radium or a combination of both, now preferably came to be treated by high or super-voltage x-ray delivering the divided doses by the Coutard principle.

The modern conception of cancer is that it represents a wide variety of disease groups. It is therefore not reasonable to expect each type to respond similarly to the same therapeutic procedure. One variety of cancer may be more successfully treated by *surgery* alone, such as gastric or colon cancer, another type by *irradiation* alone, such as cancer of the cervix, uteri, another type, by a *combination* of surgery and irradiation, another type with external irradiation by x-ray with the added introduction of radium into the tumor.

We surgeons have reached that point, in cancer therapy, where we are being confronted with the duty of informing ourselves as to which type of therapy is more effective and preferable for a particular cancer group. No modern surgeon will maintain today that surgery is the *only* method, or the best method of attacking all varieties of cancer. Cancer of the breast

has usually been considered to be a resistant type of cancer in terms of irradiation therapy. However, there are many enthusiastic reports from various radiation clinics, bespeaking enthusiasm for this method of therapy for breast cancer as a single method of treatment. Some radiation clinics maintain that it is a preferable method, to the surgical approach. Over the years past I have made a careful examination not only of these clinics but also of the written reports, and what has always impressed me has been that definite statements are made without fully presenting the pathology or the end-results of treatment. The reports that I have recently examined which include five-year end-results, have failed to convince me to date that irradiation as a single form of treatment is preferable. However, irradiation therapy is slowly and consistently improving its results so that some well-laid plan of approach to this problem of breast cancer must be made, particularly because cancer of the breast involving the axillary nodes, is more or less of a failure treated surgically.

A cross section study of the end-results accomplished by surgery alone in the good surgical clinics of America reveals that when cancer involves the breast only, sixty-five to seventy per cent five-year cure is obtained and when the cancer involves the breast together with the axilla approximately fifteen to twenty per cent five-year cures are obtained. The results of the radical amputation followed by post-operative therapy in our hands at the Memorial Hospital is seventy-two per cent five-year cures when the breast is involved alone and twenty-three per cent five-year cures when the breast and axilla are involved.

By the term "operable" is meant that the disease as far as one can tell clinically is confined to the breast or the breast together with axillary nodes. Our impression is that postoperative irradiation ther-

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 26, 1937

apy has in all probability added about five per cent to the surgical salvage. The report of end-results by Dr Bloodgood, from Johns Hopkins, is seventy per cent five-year cures by surgery alone when the disease is confined to the breast and fifteen per cent five-year cures where the axilla is also involved. In other words, surgery alone cures approximately three out of four cases if the breast only is involved. This is fairly satisfactory, but surgery only cures less than one in six where the axilla is involved. The desperateness of the latter situation is good reason for undertaking to add something to the surgical accomplishment. As a matter of fact, the present surgical operation can hardly be any further developed. Only minor changes have been added to the radical amputation during the past forty years, since the great contributions to the subject by Halstead and Willie Meyer. The only possible further development of the surgical procedure would be that of an intrascapulothoracic amputation. This would unquestionably save a larger percentage of lives, but the operative risk involved would add materially to the deaths, this procedure probably cannot be justified at present.

In general, surgery is a satisfactory procedure and its results are fairly satisfactory in the treatment of this lethal disease, *if the disease is not in the axilla*. Unfortunately, however, in half of the cases of the operable group, the disease is in the axilla, and here surgery is far from a satisfactory procedure. What is surgery doing about it? What have we done in the past forty years to improve our results where the axilla is involved? The answer is that we are doing nothing new. In other words, if our results are to improve, we must look for help in some other field than surgery.

When one breaks away from established tradition one always subjects oneself to a certain risk. Aside from this, trying a new procedure always brings with it an entirely new set of problems. This has been the case in this report which I am presenting.

Those operable cases in which there is a failure to cure are, generally speaking, not so much the fault of the surgeon or his technic, if standard procedures are carried out, as it is the fact that we are unable to

tell when we are dealing with a case which has microscopic metastases beyond the operative field. Few of us ever stop to consider what may have happened to the carcinoma before the case came to us. Occasionally we see instances where the patient has been giving herself daily massages in an attempt to make the lump disappear. Colorful and unpleasant medicines have been rubbed in. The family doctor has palpated the tumor over a period to see if the tumor is not disappearing spontaneously and too often we see evidences of the black and blue area in the neighborhood of the tumor speaking eloquently of the criminal lack of delicacy in palpation. All in all there are several reasons to account for our failure to cure the operable breast cancer. Many of the twenty-eight per cent of failures to cure in those instances where there is no axillary involvement simply mean that the villain has escaped through the back door into the liver or chest and that neither surgery nor irradiation nor both had any opportunity for cure at the time that the patient came.

This report represents a study which we initiated three and a half years ago on only the operable breast cases. Every case here reported has not only had an aspiration biopsy but it also has had the pathological study made later. Our routine, in general is the following. First an aspiration biopsy is made when the patient first comes to the hospital. The patient, if the biopsy be positive, for cancer then starts on the preoperative irradiation program. This irradiation program has varied during the past three years. We have taken certain groups of cases giving them different amounts of high voltage x-ray or the radium element pack. In a good many instances it took from four to six weeks to deliver the entire amount of irradiation. In most instances the skin was not only well-red-dened but some cases went on to blistering and even ulceration. After the completion of the preoperative radiation therapy, we allowed from four to six weeks, sometimes even longer for the irradiation effect to take place and the skin to recuperate. At the end of this time a radical amputation was performed. This was followed by most careful studies in the pathological laboratory by Dr Ewing and Dr Stewart,

to whom I owe a great deal for their co-operation. As a result of the irradiation therapy, it was found that about sixty per cent of the cases showed *clinical* disappearance of the breast tumor, and about fifty per cent showed clinical regression in the axillary nodes. We found, however, that these figures do not represent an accurate condition, as many times Dr Ewing in the laboratory found signs of viable cancer in an area where the disease had entirely disappeared clinically. The microscopic studies showed that it was rather easy to miss the original site of the tumor, after the disappearance of the tumor in the gross. Dr Stewart found that there was a characteristic scarring in these cases where the tumor had completely disappeared which was helpful in locating the original tumor site. When we did the radical mastectomy we carefully measured and marked with a black thread exactly the site of the tumor so that it would be of assistance to the pathological department. As a result of the pathological studies we have found the following:

Breast Only Treated by X-rays

1 In 141 cases treated preoperatively by the x-rays, there were thirty-four, or twenty-four per cent, in which there was complete microscopic destruction by the preoperative irradiation. In this group no trace of cancer could be found in the mammary tissue.

2 In these same 141 cases, treated by the x-ray, there were twenty-four, or seventeen per cent, in which such a disintegration of the cancer tissues took effect that we doubt its capacity to survive or regenerate (REB 3) in which the destruction was so great as to make grading of the tumor impossible.

3 It may be improper to add groups REB 4 and REB 3 (time only will settle this point) but if it were proper it would result in a forty-one per cent sterilization of the tumor located in the breast. Dr Ewing maintains that what he classifies as group REB 3 is probably incapable of survival. Dr Stewart in the same laboratory takes the position, and I think properly so, that this group should not be added to REB 4 as examples of total destruction.

It is of interest to compare the results of therapy by the x-ray and by the radium element pack.

Breast Only Treated by Radium Element Pack

1 Fifty-nine cases were treated by the

radium element pack. In thirteen or twenty-two per cent complete sterilization was accomplished in the breast.

2 In ten, or seventeen per cent of the 59 cases, almost complete destruction took place (REB 3).

3 The addition of the groups REB 4 and REB 3 treated by the radium pack totals thirty-nine per cent, which is very close to the forty-one per cent accomplished by the x-rays.

Axillary Nodes Treated by X-ray

1 Of the radium pack cases with axillary were seventy-seven having axillary involvement. Of these, five had complete sterilization of the axillary nodes, which is 6.5 per cent.

2 There were seven cases, or nine per cent where the destruction was almost complete (REN 3).

Radium Element Pack

1 Of the radium pack cases with axillary involvement, three, or eleven per cent, had complete sterilization of the nodes.

2 There was one instance, or 0.4 per cent, in which there was almost complete destruction.

We therefore find of a total of 200 cases treated by irradiation therapy that we have forty-seven of complete sterilization or complete microscopic disappearance of the tumor from the breast. This is 23.5 per cent. This is lower for this large series than my previously published report of a smaller series where I obtained sterilization in thirty-three per cent when treated more heavily. When it comes to the axilla we have 104 cases with axillary involvement and obtained complete microscopic sterilization in only eight, representing eight per cent. Although these figures are impressive, as showing that we have another agent which can be employed in combatting this disease, still it presents a far from satisfactory weapon in our hands today.

There is renewed talk today of ovarian sterilization in cases of mammary cancer. Some reports are impressive but no large groups are reported which are very convincing of *permanent* cure. However, the laboratory studies, particularly those of Little, together with our clinical experience, would indicate that this form of therapy is more than justified. In my own

practice, I sterilize women who still menstruate, if the disease is *extensive* or even in cases of young women with axillary disease

Lord Monahan stated to a formal group at the Memorial Hospital a few years ago that he had lived to see the end of the radical mastectomy for cancer. He had been greatly impressed by the work of Geoffrey Keynes in London.

Dr. Carl Eggers stated in the December 1932 *Annals of Surgery*, "Various statistical reports dealing with the late results after operation of cancer of the breast make one feel that no real progress is being made. We are at a standstill and a feeling of pessimism regarding the entire subject may be noted. Perhaps the best reports come from those clinics combining radical surgery with post-operative irradiation."

One of the unfortunate complications of heavy irradiation is pulmonary pneumonitis or fibrosis of the lungs. Mild irradiation over the chest wall does not produce this condition. In this series the fibrosis was noted more particularly where our dosage went up from 1,800 roentgen units per port to 2,400 per port. Fibrosis is denied by some radiologists and by others it is stated that fibrosis will be obtained only where there is improper technical application. It is very difficult in certain instances such as a case of carcinoma in the upper inner quadrant of the breast, to keep from directing the irradiation beam into the depth of the lung. In certain instances of very thin women with small breasts flattened on the chest wall, it is difficult not to give irradiation which may cause fibrosis. In our series we have obtained fibrosis in about eight per cent of the cases. This is a condition which is very distressing to the patient. It produces coughing and a certain amount of discomfort and pain. Fortunately, many of the symptoms clear up at the end of four or five months as the x-rays will demonstrate.

The x-ray film shows that frequently there is a pulling up of the diaphragm with adhesion between diaphragm and lung. There may be a deviation of the trachea to the side which is irradiated. There is also rather a dense shadow in the lung which is commonly confused with metastasis. This appearance is one which

requires a radiologist of some experience to distinguish. In other words, x-ray therapy has produced a *new* disease of the lungs, about which the radiologist and clinician must now become familiar.

Another condition which may meet with great objection particularly on the part of the surgeons is that of delay. Many surgeons accept the view that on the day the definite diagnosis of cancer of the breast is made, the patient should be operated on. This study does not bear out this point because the tumor begins to diminish as a rule when the treatment is begun. However, as it is impossible to prove these points except by the passage of time, we must be content not to give this too important a place in our considerations. After all, the main effort involved in giving preoperative irradiation is to prove or disprove whether or not we have larger percentage of five year cures when we employ preoperative irradiation or whether we do not.

If the life expectancy in this group of cases could be improved by five or ten per cent, I assume that the unfortunate complications of preoperative irradiation would be justified and worthwhile.

There is another complication which has arisen in these cases where heavy irradiation has been employed. The wound healing is very much poorer than in unirradiated cases. There is a characteristic story that goes with these cases. The breast and surrounding tissues are fibrosed and there is much more bleeding and difficulty in doing the operation than in other cases where there is no preoperative irradiation. There has been such a marked endarteritis and such a cutting-down of the blood supply to the tissues, that capacity for healing is greatly diminished. The wound may pull apart and result in separation. This open wound may take weeks to heal. In this series we have had two instances in which there has even been necrosis of a rib.

Although lymphedema is encountered entirely too frequently even in those cases having no preoperative irradiation, it has more reason to occur and does occur more commonly in the irradiated case due to poor wound healing. This distressing complication should not be considered lightly. In those cases previously irradiated the muscles in the region of the shoulder are

often fibrosed so that arm function is diminished. There is an unknown factor which no one has yet measured. We know by experience that muscle tissue easily undergoes fibrosis as a result of irradiation. In many of our cases of breast cancer on the left side, the heart muscle unquestionably receives its full share of rays. It remains to be seen whether or not there is any cardiac damage of a permanent nature to be derived.

You may ask why we operated on the patient after such heavy irradiation. It is because we know that surgery produces a definitely known percentage of cures in mammary cancer, and we must not deny that patient his fair chance. But by the addition of preoperative irradiation, we will be able to soon compare the accomplishments of the two methods. The five year period will not be completed before eighteen months, then we can state facts.

There are those bolder than I am who are satisfied to give only irradiation for this rather resistant type of cancer. But to date their cases treated are too small to be of very imposing statistical value.

Conclusions

I repeat that this work has carried with

it many distressing complications. It has also proven that external irradiation given by the high voltage x-rays and by radium pack has capacity to entirely sterilize mammary cancer in about one case out of four. With the present technic as we have used it, it has sterilized axillary disease in only one in ten cases. This group of 200 cases is being reported to you as a piece of clinical research in the course of investigation. The main conclusions are yet to be drawn and it will not be possible to do that until the five year period has lapsed. I would like to emphasize here that preoperative irradiation is something which should be employed judiciously. Heavy irradiation should not be employed to large ports in the aged. The indications are that we will probably next turn our attention to irradiation of only those cases in which there is axillary involvement. In this instance both external irradiation with the addition of interstitial radium must be employed if radiation is to compete with surgery. Due to the fact that mammary cancer can be sterilized, if a proper technic be employed, I am still hopeful that irradiation will play a part in the ultimate treatment of this disease.

THREE DOORS FOR THE NEW M.D.

General practice, whether in town or country, is entered in one of three ways, says an English book called "A Guide to General Practice." The newcomer may take a house, put up a plate, and wait for work to come to him, he may buy the goodwill of a practice rendered vacant by retirement or death, or he may become a partner in an established firm. The first is more risky than the second, and the second than the third. A well-managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress of medicine. Success in private practice demands a great deal of knowledge beyond that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience as an assistant or deputy.

TRENDS IN OBSTETRICS

LESTER R. MELLOR, M D, Syracuse

To physicians interested in maternal and fetal welfare, I thought it very fitting to present a statistical resume of obstetric procedure and trends during the last eighteen years. This includes fifteen years, closing period at the University Hospital, and three years of data from the General Hospital of Syracuse.

The first fifteen years cover 7722 cases, while the last three years cover 1584, a total of 9306. Cases are grouped in from three to five year periods and are grouped into three tables to facilitate clearness (Table I).

From 1917 to 1921, a four year period of 1987 cases, 218 or nine per cent were forceps cases, forty versions were performed or two per cent with ten fetal deaths, mortality rate of twenty-five per cent, there were seventy-seven breech cases with twelve fetal deaths, a mortality rate of 156 per cent. Stillbirths numbered ninety-nine, a rate of 39 per cent, placenta previa showed eighteen with five fetal deaths, a mortality rate of twenty-eight per cent, there were two ablatio placenta and thirteen cases of eclampsia with two fetal deaths. Twelve sections were performed with one maternal death, a mortality rate of nine per cent.

You will observe that I have grouped these data in order to show the trend of procedure in modern care of obstetrical cases. Progress may or may not be observed.

The second period, 1921-1924, is a three year period showing 1186 obstetrical cases with 129 forceps, an incidence of about ten per cent. Fifty-four versions were done, an incidence of 45 per cent with seventeen fetal deaths, a rate of 315 per cent, an appalling figure. Inasmuch as the difficulty of labor for which version was performed is not evident, criticism should be withheld. Forty-six breech cases, nineteen fetal deaths, another startling figure of 413 per cent mortality. Again we must hold our opinion *sub judice*, remembering that all of this data includes the work of private physicians, obstetricians, general practitioners, surgeons, gynecologists, and interns more or less under the tutelage of attending obstetricians. Watch these same

statistical series in later years when specialism has become more assertive. There were fifty-seven stillbirths in this period, a rate of 45 per cent, three placenta previa with three deaths of infants, two ablatio placentas and eight eclampsics with three fetal deaths and one maternal death. Seven sections for this period with one fetal and no maternal deaths.

The third period (1924-1929) was a five year span showing 2835 cases with 547 forceps deliveries—about twenty per cent. One hundred and one versions, 35 per cent of the whole number with twenty-nine fetal deaths or about twenty-nine per cent mortality. Breech cases numbered 111 with twenty-one infant deaths, a much reduced mortality rate to twenty per cent, 117 stillbirths or 45 per cent, placenta previa was present in twenty-two cases with fetal deaths of thirteen or sixty per cent, maternal considered later. Three ablatio placentas, thirteen eclampsias with three mothers and fetuses dying. In this group were forty-nine sections, one maternal and three fetal deaths. Maternal rate of 17 per cent. This period shows improvement in all figures.

The fourth period (1929-1932) covers three years and 1714 cases. Forceps were used in 447 deliveries an incidence of twenty-six per cent or more than one in four. Seventy versions showing that this procedure was used in 45 per cent of cases with fourteen fetal deaths, twenty per cent mortality. Fifty-three breech cases with eleven fetal deaths makes a mortality rate of about twenty-one per cent. There were sixty-seven stillbirths or 39 per cent. Placenta previa claimed three cases, all babies dying, three ablatio placentas, and one eclampsia with fetal death. Cesarean section was performed sixty-six times, with three fetal and two maternal deaths, this rate being 38 per cent.

Averaging the total fifteen years with 7722 cases, we find 1332 were delivered with forceps, an incidence of 173 per cent. Versions claimed 265, of which seventy or 265 per cent were stillborn. 287 breech cases with sixty-three fetal deaths gives a rate of twenty-two per cent mortality. A total of 340 stillbirths gives a rate of 44 per cent, 136 postnatal fetal deaths or 17 per cent were later tabulated making a total

*Read before Maternal Welfare Meeting of the Onondaga County Medical Society,
April 22 1937*

fetal death rate of 61 per cent which includes the first ten days of fetal life. The forty-six cases of placenta previa with twenty-four fetal deaths, makes a tragic mortality rate of forty-nine per cent—a terrific toll of fetal life some of whom

might have been saved by section. Five maternal deaths occurred from this complication, eleven per cent maternal mortality. The ten recorded ablatals recorded ten fetal deaths, no maternal deaths. Thirty-five eclamptics with six maternal and nine fetal

Maternal deaths numbering 21 in 7 722 obstetric cases are included.

deaths. A total of 134 sections had four maternal deaths, three per cent rate of mortality, while the seven fetal deaths make a rate of 52 per cent. Placenta previa incidence is 1 in 166, ablatals 1 in 772, eclampsics 1 in 226, and section was performed once in 58 cases. The increased use of section in many of these complications has markedly reduced maternal and fetal mortality.

Table II covers a three year period, with resulting statistical data. You will notice the increase in relative use of forceps—as high as thirty-three per cent in 1936. Version incident although low is still high in fetal mortality. The same holds true with breech delivery.

In maternal deaths for these 1584 cases three might have been prevented, possibly the eclamptic and the infection cases.

The complications next shown demonstrate a reduction in incidence which also tends to reduce the incidence in stillbirth. In regard to sections, our incidence took a great jump, but without any maternal mortality it must be assumed that it saved some lives, inasmuch as all complications were reduced in incidence of maternal and fetal deaths (Table III).

Fetal deaths, stillbirths and postnatal, seem to indicate that better prenatal care might have saved the premature infants from fatality.

Hospitals associated as ours (Syracuse University and Generals), cannot help but have an increased incidence in the use and selection of section as a means of delivery in those conditions where any other method would increase the hazards of mother and child. A consultant's work requires the selection of the best method to be applied to the case in hand and he acts upon that theory. Naturally as true physicians, we all do likewise.

Episiotomies are shown in relative frequency together with first and second degree tears. This item, I believe, requires closer study in the practice of us all.

While the incidence of puerperal infection death is about doubled in these figures it only involves two deaths, but at the same time, they die from infection and that is where our technic should be faultless.

The total maternal deaths—26 in 9306, an incidence of 1 in 358, and a mortality rate of .28 per cent—compare very favorably with statistics elsewhere.

Can we as general practitioners and specialists set our sails in the trends of modern obstetrics and travel safely? Is it all clear sailing or must we always

use our best judgment with the case presenting? The latter surely.

What can we learn from these statistics of eighteen years in private and ward work at the University and General Hospitals?

We have learned that podalic version, a very necessary form of delivery at times, has been used considerably less. The incidence of this procedure having been reduced from 3.4 to 1.2 per cent, a reduction of about three hundred per cent and fetal mortality reduced from twenty-six and a half to ten per cent.

When version was at high tide, 1921 to 1932, the mortality rate of version deliveries was very high, but in later years, from 1929, when obstetrics became more of a specialty, the fetal death rate declined rapidly until at the present it is at ten per cent. This is still too high, as DeLee considers six per cent the proper rate.

The incidence of breech cases was reduced from 3.75 to 1.8 per cent but the fetal mortality rate is still very high—twenty per cent and according to DeLee, it should be about five per cent. While there is at present no procedure which can vary the incidence of breech, a better prenatal care of the mother may make these cases less frequent. Our technic should be improved by "watchful waiting" for complete cervical dilatation and maintaining flexion of the head in delivery.

One of the greatest trends in obstetrics has been the use of forceps, nine and one-half to twenty-six per cent in fifteen years (averaging 17.3), and increasing at the General Hospital from eighteen to thirty-three per cent, averaging twenty-three during the last three years. A discussion upon forceps could be very lengthy, but I will simply state that forceps have in many cases safeguarded the lives of both mother and child, but too often are used to save time for the hurried physician, endangering the patient with resulting lacerations or prompted episiotomies.

The incidence of episiotomy has greatly increased. Needless to say there are indications for this operation, but also there are cases where this operation should never have been done. One slit ahead of the baby, seems to be the slogan of some doctors, in handling para cases.

Stillbirth rates vary according to the

difficulty of the cases and the method employed in their delivery. This lowered rate is properly credited to a better selection of method of delivery in those borderline cases, requiring the best judgment in procedure—4.4 to 2.3 per cent with postnatal deaths from six to 3.5 per cent.

With world mortality rates as high as they are in section delivery, our increase in section procedure also must be looked upon critically. After such an examination of the records, we find a marked reduction in maternal mortality, from three to 1.7 per cent average for all sections.

The use of cesarean section as a method of delivery has come to the fore with great rapidity in the last few years. There is no obstetric procedure aside from the treatment of eclampsia about which so much has been written. Most of these papers state mortality rates which vary from fifteen to as low as one per cent in fairly long series of cases.

In 9306 obstetric cases, section was performed in 224 cases or 2.4 per cent. Of late this rate has risen to 5.7. The mortality rate fell from three per cent to an average of 1.8 and if we limited our count to the last 100 considered, the mortality rate would be nil. Section, when properly performed upon cases to safeguard the lives of mother and infant, loses the high death rate and becomes a very

valuable procedure in the saving of human life. Unquestionably there are too many performed where the method of delivery should have been otherwise and unquestionably there are too few done where there should have been section performed.

Poor results in obstetrics are not caused by the use, but by the abuse of obstetric surgery.

Watchful waiting is an essential virtue in obstetrical management, but look out for criminal procrastination just around the corner.

The number of eclampsia cases reduced in frequency from one in 226 to 264, the mortality severity, one death in 1544 compared to 1584.

The incidence of placenta previa was reduced from one in 166 to 518, the mortality rate disappearing almost entirely.

Ablatio placenta decreased from one in 772 to 792. Puerperal infection frequency increased from one in 1544 to 792, this being the mortality rate.

Voltaire has said, "Perfection is attained by slow degrees, she requires the hand of time." Herbert Kaufman made the trite saying, "If old ways were best, there would be no room for betterment. In an age of progress you can never be sure of yesterday's judgment and today is but a threshold. The land of promise is ahead."

123 WINDSOR PL.

TO AID DEAF CHILDREN

Governor Herbert H. Lehman July 5 appointed seven of the thirteen members of a temporary state commission, created by the last Legislature, as a step looking toward bringing about an improvement in the care of deaf children. The other six on the commission are members of the Legislature, appointed by Speaker Oswald D. Heck, of the Assembly, and Senator Jolin J. Dunningan, president pro tem of the Senate.

The commission is specifically authorized to examine, report on and recommend measures to improve facilities for the care of hard of hearing and deaf children and children liable to become deaf. The Governor's appointees include Dr. Edward S. Godfrey Jr., State Commissioner of Health, and Dr. Frank P. Graves, State Commissioner of Education, as ex-officio members. The other five appointed by the Governor

are Dr. Augustus J. Hambrook, of Troy, chairman of the committee for deaf and hard of hearing of the State Medical Society, Miss Estelle E. Samuelson, executive secretary of the New York League for the Hard of Hearing, Inc., and member of the board of managers of the American Society for the Hard of Hearing, Dr. Emily A. Pratt, supervisor of eyes and ears, State Education Department, Albany, Dr. Edmund Prince Fowler, director of research and clinics, New York League for the Hard of Hearing, and Captain Victor Skyberg, principal of the New York School for the Deaf.

The legislative members are Senators Livingston, Rogers, and Hastings, Assemblymen Miller, Black, and one Assemblyman yet to be appointed. The Legislature appropriated \$5,000 for the commission expenses.

Preventive Medicine

Preventive Medicine and Tuberculosis

CHARLES H. GOODRICH, M.D. Brooklyn

We are here to initiate among our fellows in the Medical Society of the State of New York, the campaign for Preventive Medicine, suggested to and adopted by the House of Delegates as a prime duty and effort for the current year. Here begins a series of talks to District Branches, each one of which will bring before our members a specific problem in prevention. We shall feel honored and encouraged if you will follow these addresses as published and lead your respective county societies into vigorous activities. May these efforts of yours awaken the profession and public to the advantages of prevention and early elimination of disease (which is realistic prevention) so that a new era may dawn. In this new day we have only to apply knowledge long possessed. However, the public must appreciate the advantage of preventive medicine, else how can we practice it? Directly and indirectly we should popularize this new type of practice largely by the written or spoken word and graphic illustration. Speak of it to lay audiences whenever possible—always *urgently* and *dramatically*!

In all this we will be giving new life to the work of State Departments of Health and Welfare. From the evidence in hand I can assure you that these departments will afford us enthusiastic cooperation.

We spoke of presenting specific problems. What practical value could evolve from generalization? One by one outstanding examples can be discussed with the hope that the massing of evidence, along a large front battle line, will some time render obsolete the desire to cure or be cured of an *advanced* disease, because of a *unified* desire to anticipate such occurrences.

We present a few remarks about the most protean disease extant. Old Proteus was a marine god who could assume any form or shape he chose. Hence he was variable, in form, color, and agility. Thus when we say most "protean disease" 100% of you have guessed "Tuberculosis." Known

to have existed five thousand years, probably longer, its pulmonary manifestations were described by Hippocrates (460-377 B.C.) under the name *Phthisis*.

That it was a communicable disease was believed by Isocrates, a contemporary of Hippocrates. The doctrine of infectivity was not well developed in the mind of physicians for centuries many holding the conviction that heredity was the cause. Sylvius (1614-72) described what he called "tubercles" in the lungs which gave origin to the term *Tuberculosis*. In 1700 Mag-netus gave a minute description of a military tubercle. Morgagni (1682-1772) wrote of his dislike in dissecting bodies of tuberculous persons because of "fear of infection." Thus was the way paved for Laennec (1781-1826) to unquestionably establish the beginning of the modern conception of the unity of tuberculous lesions. Laennec also considered it dangerous to do postmortem examinations and insisted upon precautions. He ultimately succumbed to the disease traceable to an injury at necropsy. Villemin in 1861 published proof that tuberculosis was specific and inoculable disease. Then can Koch in 1882 to demonstrate his tubercle bacillus.

Since that Red-letter day tremendous efforts have been made to cure, arrest, remove and prevent tuberculosis. Of all this you have knowledge stored and available upon demand. Reliable literature is massed in every medical library. Health departments of States, counties, cities, towns, and villages, serve capably. Their efforts, with the cooperation of practicing physicians, have resulted in the reduction of mortality and incidence. With our reduction in mortality we must remember that this is *not necessarily* synchronous with reduced incidence for persisting cases are much greater in number than the death rate indicates, especially under modern treatment and care. Despite zealous efforts tuberculosis remains the most insidious, universal,

Delivered at the Annual Meeting of the Sixth District Branch of the Medical Society of the State of New York, Oswego, September 21, 1937

kaleidescent disease, the focus or foci most commonly discovered in advanced degrees of degeneration or disintegration. Its ravages follow civilization especially where we are civilized in large massed groups. In proportion as men have dwelt on mountain or prairie, living largely out of doors, greater freedom from infection is found.

In organizing a renewal of the campaign for the prevention or early recognition of tuberculosis compare our "man-power" to that of a foot-ball team. The Health Departments, financed and directed by the state and local governments, furnish the runners who cover much ground, the half-backs and full-back, and the quarter-back who calls the signals. What can they do against the 5000 year old tubercle bacilli deployed all over the field, without a strong scrimmage line? With the general practitioner as center-rush, scent-genologists as guards, surgeons at tackle, and specialists on the ends we may have some chance of winning.

Heartly cooperation is therefore most desirable.

How *elusive* is the havoc wrought by tubercle bacilli has often been told. Twenty-five years ago when "nervous prostration" was a common diagnosis, a Minneapolis neurologist saw such a case with an apical lesion which proved to be tuberculosis and was successfully treated. Thereafter he found twelve cases of pulmonary tuberculosis in his next fourteen "nervous prostrations," and instituted rational treatment.

We are told, on exceptional authority, that over ninety different diagnoses have been formerly made to indicate cases of tuberculosis—all of them misnomers or errors. Perhaps the most outstanding is "pleurisy" which reminds us that all pleurisies in children or young adults should be suspected of tuberculosis.

We are prone to forget or have no opportunity to discover that tuberculosis is common among *elderly* persons. It usually remains unnoticed or is considered merely chronic bronchitis or asthma by the family. This fact is one which we should broadcast to the public. With physical signs, positive x-ray findings, and bacilli in sputum, these precious old people are carriers to all and especially to the children of the household. Let us examine the chests of the aged with extraordinary care and carefully classify and treat open cases as carriers menacing

others. Most old people are mellow and considerate enough to cooperate.

Regarding the environmental precautions routinely required in homes, factories, schools, offices, and all public places, it is unnecessary to dilate before this audience. It is enough to urge that discernment, courage, persistence, public spirit, and personal work be developed by all physicians in every community to secure these primary hygienic provisions for safety for all of our neighbors. The dangers in unregulated milk supply must also be overcome. Tuberculous cattle must be eliminated because infected meat is sometimes sold by unscrupulous butchers.

The positive preventive measures applicable to all children and adults alike are

1 Nutrition of the highest order sagaciously balanced

2 Rest in full doses every day

3 Air as fresh and pure as is possible with frequent deep breathing

To intelligently start on our campaign of prevention we must recall that most original infections are acquired in childhood. It has been established that most children of the working class in cities are tuberculized before the age of fifteen. This is where our hunt for early lesions should start. And while we are starting remember that wealth and luxury do not protect the spoiled or hot-house child. We must remember that tuberculosis in the child does not always appear first in the lungs. Bones, joints, tonsils, lymph-nodes, peritoneum, and gastrointestinal tract must be under suspicion. Even in adults the lungs may be uninvolved. Six years ago came a plump rosy, farmer's wife to the Methodist Hospital in Brooklyn for treatment of a tumor of the chest wall. Operation revealed tuberculous chondritis of costal cartilages. She was discharged cured after two generous excisions and there has been no local recurrence. Two years later she developed a tuberculous osteitis of lower cervical and upper dorsal spine. Immobilization with a tibial bone-graft and plaster jacket cured this lesion. She is still fat and rosy and three months ago failed to show any x-ray or other evidence of tuberculosis of lungs.

We all know that certain "losses" occur early in tuberculosis.

Loss of appetite—no hunger

Loss of color—no rosy pink skin

Loss of weight—no curves—only angles

Loss of energy—tired with little or no reason

Two or more of these subjective symptoms should lead us to suspect tuberculosis, especially in childhood. This holds also in adolescence and early adult life (at least up to thirty). This is the simplest, crude rule for discovering tuberculosis in its early stages—which is quite comparable to the prevention of most other diseases. Let us therefore, for our present purpose, broaden the definition of "prevention" in tuberculosis. The case detected in early stages and readily arrested (or cured) may reasonably be regarded as a prevented case—provided a competent follow-up scheme follows adequate treatment.

The general practitioner at present has the largest opportunity for discovering early tuberculosis. To his attention will be drawn loss of appetite, or of energy, or of weight or of color. Loss of appetite or energy may be reported by patient or by parents. Discovery of loss of weight or color will more often be left for the physician. Any combination of these "losses" should inspire careful, thorough, physical examination of the disrobed patient, not "just a tonic for you are run-down." If no definite cause can be assigned, even if lungs seem clear of physical signs, a *cutaneous tuberculin test* should be applied and an x-ray film of chest should be taken to "exclude" pulmonary tuberculosis. In the history taking of such a case, care should be taken to discover possible contacts with existing tubercular cases. This may require diplomacy but is important. However, the question of contact should begin at the known existing case radiating from this point.

Thus we arrive at one factor in prevention which we should emphasize professionally and publicly, the regular complete periodic examination of all persons who are or who have recently been in contact with a known open case of tuberculosis early or advanced, whether such contacts are in home, factory, office, school, hospital or elsewhere. This calls for an elaborate, expensive program and can only be assured by definite continuous cooperation among health departments, physicians, lay-organizations, and the public generally. Such examinations are of definite economic value and self-sustaining persons and families can look upon them as insurance reasonably priced when paid for in fees commensurate with those prevailing in the community. For those in the group who are able to pay partially, special office-hours can

be held for examinations at a moderated price. For the indigent, the state or community health department should pay the examiner a minimum price to be determined upon by conference between the department and the county or state medical organizations. We believe that the greatest cooperation can be obtained by engaging the active interest of the physicians of the state, and that ultimately, if this work at minimum fees be sent to their offices, there will be a greater advance in the prevention of tuberculosis than by any other method of examining contacts. That this *seems* to mean much self-sacrifice for physicians is unquestioned. However, we must here prove our devotion to the principles of altruism so long a feature of the average physician's life. Nor must we forget that some measure of success attends the business principle that large volumes of services at small returns often compare favorably with small amounts of service at standard prices. The havoc in mortality and morbidity attending free contacts without examination is well known to those who have studied long service of cases. In one instance cited by Sir Robert Philip—the original patient had fourteen family contacts who were infected, six of whom had died at the time of final record. That tuberculosis is a disease of households has long been known. The full significance of this has only dawned upon us in recent decades. Hence the logic of periodic examination of all contacts in the home of the patient, among visiting relatives and friends, and fellow-workers.

The next preventive factor to emphasize may overlap the examinations of contacts. So be it—as it is the *measure of greatest importance*. Intensive searching for early cases in the *minimal stage* has often been recommended. Methods to accomplish this have been suggested. Henry Vaughan's "Detroit Plan" patterned after the successful Diphtheria campaign of 1928 to date, but more intensive, extensive and expensive, seems the best thus far. He told us about this at Atlantic City and we hope that you will all read his article studiously. (This has been published in the *Journal of the American Medical Association*, September 4.)

Eight hundred physicians of the Wayne County Medical Society are cooperating by agreement to examine cases, make tuberculin tests, and provide x-ray films where cutaneous reactions indicate infection or physical signs indicate lesions. Many of the four hun-

kaleidescopic disease, the focus or foci most commonly discovered in advanced degrees of degeneration or disintegration. Its ravages follow civilization especially where we are civilized in large massed groups. In proportion as men have dwelt on mountain or prairie, living largely out of doors, greater freedom from infection is found.

In organizing a renewal of the campaign for the prevention or early recognition of tuberculosis compare our "man-power" to that of a foot-ball team. The Health Departments, financed and directed by the state and local governments, furnish the runners who cover much ground, the half-backs and full-back, and the quarter-back who calls the signals. What can they do against the 5000 year old tubercle bacilli deployed all over the field, without a strong scrimmage line? With the general practitioner as center-rush, scent-genologists as guards, surgeons at tackle, and specialists on the ends we may have some chance of winning.

Hearty cooperation is therefore most desirable.

How *elusive* is the havoc wrought by tubercle bacilli has often been told. Twenty-five years ago when "nervous prostration" was a common diagnosis, a Minneapolis neurologist saw such a case with an apical lesion which proved to be tuberculosis and was successfully treated. Thereafter he found twelve cases of pulmonary tuberculosis in his next fourteen "nervous prostrations," and instituted rational treatment.

We are told, on exceptional authority, that over ninety different diagnoses have been formerly made to indicate cases of tuberculosis—all of them misnomers or errors. Perhaps the most outstanding is "pleurisy" which reminds us that all pleurisies in children or young adults should be suspected of tuberculosis.

We are prone to forget or have no opportunity to discover that tuberculosis is common among *elderly* persons. It usually remains unnoticed or is considered merely chronic bronchitis or asthma by the family. This fact is one which we should broadcast to the public. With physical signs, positive x-ray findings, and bacilli in sputum, these precious old people are carriers to all and especially to the children of the household. Let us examine the chests of the aged with extraordinary care and carefully classify and treat open cases as carriers menacing

others. Most old people are mellow and considerate enough to cooperate.

Regarding the environmental precautions routinely required in homes, factories, schools, offices, and all public places, it is unnecessary to dilate before this audience. It is enough to urge that discernment, courage, persistence, public spirit, and personal work be developed by all physicians in every community to secure these primary hygiene provisions for safety for all of our neighbors. The dangers in unregulated milk supply must also be overcome. Tuberculous cattle must be eliminated because infected meat is sometimes sold by unscrupulous butchers.

The positive preventive measures applicable to all children and adults alike are:

1 Nutrition of the highest order sagaciously balanced.

2 Rest in full doses every day.

3 Air as fresh and pure as is possible with frequent deep breathing.

To intelligently start on our campaign of prevention we must recall that most original infections are acquired in childhood. It has been established that most children of the working class in cities are tuberculized before the age of fifteen. This is where our hunt for early lesions should start. And while we are starting remember that wealth and luxury do not protect the spoiled or hot-house child. We must remember that tuberculosis in the child does not always appear first in the lungs. Bones, joints, tonsils, lymph-nodes, peritoneum, and gastrointestinal tract must be under suspicion. Even in adults the lungs may be uninvolved. Six years ago came a plump rosy, farmer's wife to the Methodist Hospital in Brooklyn for treatment of a tumor of the chest wall. Operation revealed tuberculous chondritis of costal cartilages. She was discharged cured after two generous excisions and there has been no local recurrence. Two years later she developed a tuberculous osteitis of lower cervical and upper dorsal spine. Immobilization with a tibial bone-graft and plaster jacket cured this lesion. She is still fat and rosy and three months ago failed to show any x-ray or other evidence of tuberculosis of lungs.

We all know that certain "losses" occur early in tuberculosis.

Loss of appetite—no hunger.

Loss of color—no rosy pink skin.

Loss of weight—no curves—only angles.

Loss of energy—tired with little or no reason.

The "Detroit Plan" seems so important that in our Saratoga address to the Annual Convention of Health Officers and Nurses, we recommended an examination of its method and workings by a joint committee from the State Health Department and the State Medical Society "at the arena in Detroit." The Commissioner has appointed a Committee from the Department and ours was approved at the last Council meeting.

We have thus emphasized

1 Team work—the need for cooperation of our Society with the State Health Department.

2. The early tuberculization of children usually the primary infection

3 The unsuspected tuberculosis of the aged

4 The earliest symptoms—losses (W-A-C-E.) Weight, Appetite, Color, Energy

5 Thorough physical examinations of suspicious cases (Not of very great value)

6 Tuberculin tests All positive reactions should have x-ray films of chest at any age, especially ages fourteen to thirty years

7 Roentgenogram of lungs if symptoms, appearance, physical signs, or cutaneous test suggest possibility of tuberculosis

8 The significance of tuberculosis as a communicable household disease

9 Importance of control and management of cases Isolation of all open cases either in institutions or at home with rigid sanitary control

10 If there is no lung lesion look elsewhere especially in children

11 Suspect all chronic fluctuant or semi-fluctuant tumors in children or adults

12 Periodic examination of all contacts including x-ray examinations of chest

13 Intensive early case-finding to prevent and halt spread of tuberculosis—saving lives and private and public moneys

14 The importance of the Detroit Plan

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B. LIBER, M.D., DR. P.H., *New York City*

Editorial Note Under this title will appear short summaries of 'transition cases' from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

The Child Artist

Here is a story of a child artist which has its importance because it shows how conflicts can be avoided and mental health conserved—incidentally also how genius is developed instead of being ignored or hampered.

One evening, many years ago, long before I specialized, responding to a telephone call, I went to see a little girl of four who was suffering from measles. She also had a very sore throat and high fever. On account of the complete eruption which covered much of her skin it was impossible to distinguish her features. But that her complexion was brown could be seen by her very dark hair and vivid black eyes. The first impression was that she was good-looking—and this was fully confirmed later.

She was not in bed and although I endeavored to examine her as thoroughly as possible she paid but little attention to me. She was busy drawing. She knelt on a chair and did her work on the table. Several writing pads were piled up near her and as she filled one page after another, she threw them down on the floor which was littered with these white sheets covered with pencil pictures. Dwelling in another world, nothing seemed to awake her from her dreams.

Her mother felt very ashamed and apologized by saying that she allowed the child all this paper only because of her illness. Otherwise she would not let her spoil so much valuable material. If left alone this girlie would soil all the walls with her fancy and foolish stuff and carve the good furniture with her father's pocket-knife. Oh mother knew how to punish the little rascal for her sins.

Indeed, upon closer inspection, I noticed some wonderful carvings on the corners of the table. There were some heads full of life. And as I picked up the drawings from the floor I gasped. I saw extraordinarily well done works of great art. Some subjects were sad others gay or satirical. There was the street, alive with houses and peddlers and drunken men, children were playing—and so on.

There was no opposition when I put some of the papers in my pocket.

I came again—and I tried to convince the mother that her child was a real artist, a great and rare artist. But she was offended. She said "Please, do not make fun of us poor people."

Only after I had some of the pictures

dred and thirty public-health nurses are in the field visiting homes and referring all suspicious cases and contacts with known cases to their family physicians for examination. If there is no family physician the nurse presents a card giving names and addresses and hours of all of the physicians in the district (there are thirty-five districts). Solvent people pay the physician's regular fee. Poorer people pay less at a special hour noted on the cards. Indigents receive special cards which provide for free examination. When these cards are sent to the health department for record the physician receives one dollar for his examination including cutaneous test (materials furnished by department), three dollars for x-ray film, and one dollar for re-examination after film is examined and consultation completed with the roentgenologist. Except when the physician himself uses x-ray, all films are made by specialists in roentgenology, members of the Detroit Roentgen Ray Society, who cooperate with the department and the county society. "This society has appointed a committee to which are referred all doubtful and positive films by whomsoever taken, and the committee's judgment is transmitted to the examining physician" (Vaughan).

This campaign began February 1, 1937, following two months of front page newspaper stories and radio dramas. The City Council appropriated two hundred thousand dollars per year for five years to be used exclusively for case finding work. It is expected that this expenditure will save lives, lessen needs for hospitalization, and ultimately reduce the cost of tuberculosis for the taxpayer.

While it is true that there are many danger spots in tuberculosis it was decided in the program to limit the intensive case-finding efforts to three definite undertakings. Into every physician's practice come those individuals with a history and appearance which suggests tuberculosis. They may be considered the suspects for whom an examination is indicated as a possible means of revealing suggested signs of this disease. The tuberculin test will generally establish the presence or absence of infection with the tubercle bacilli. This, followed with an x-ray of the chest of the positive reactor, will reveal in detail much that cannot be detected by physical examination alone. Then, a special search should be made of the contacts to the active case of adult type tuberculosis. Household contacts come under immediate suspicion on two accounts—first, if the person

already found is a positive sputum case, one or more of the other members of the household may have acquired tuberculosis from him, second, if the person already found does not have positive sputum, one of the other members of the household may be the source of infection and should, therefore, be detected. There are certain groups in the community who may be regarded in almost the same light as household contacts. Such, for instance, as residents in those districts of the city in which the tuberculosis mortality is high. These areas should be well-known to the health department and information regarding same should be made available to all cooperating physicians. Thus, the immediate objective has been to reach these three groups, first, those in the practice of the physician whom they suspect of being tuberculous, second, household contacts of definitely diagnosed cases, and third, persons residing in areas in which the mortality from tuberculosis is excessively high (Vaughan).

The results of this work (to May 31, 1937) are most encouraging. Over thirty-five thousand tuberculin tests were done with twenty-two per cent positive. Sixty-nine per cent of those had completed x-ray studies and 242 new active cases had been discovered, of which forty-three per cent were minimal.

In one large mid-western county, two and one-half million dollars of public money is being spent annually to hospitalize tuberculosis cases. This cares for twenty-five hundred hospital beds,—more than twice the annual number of deaths. In the past few years only 13 per cent of cases reported to the health department by the family physician was minimal. When, to this, is added the follow-up of contacts and school examinations by health department, the per cent of minimal cases is raised to 20. There are but few American communities which report as high a per cent of early cases. Four out of five cases are already either moderately or far advanced. The average period of hospitalization for the early case is eight to nine months. The advanced and far advanced case requires twice that period of hospitalization. It is at once apparent that by increasing the per cent of minimal from 20 to 50, the hospital load would be proportionately reduced and the community would save more than one million dollars in annual hospital bills. In other words much, if not all, of the money being spent for hospitalization should never be spent. There should be no cause for its expenditure. Finding the early case will reduce the hospital load and expense, and save money. The diversion of a fraction of this saving in hospital bills to adequate case finding facilities would be good economy.

EDITORIALS

On Guard!

There was intense professional consciousness of the threat to high quality medical care prevalent among us in the Spring. Due to the summer vacation and the quiet that has resulted from the recess of the legislatures, and the paucity of articles on this topic in the news columns of both lay and medical press, this consciousness seems to have abated somewhat, and we fear the profession is lulled into a feeling that the issue is past.

The discussions and clarifying conceptions which emanated from the last meeting of our House of Delegates would, it seems to us, have been indicators of competent medical opinion. The reports of the A M A session gave additional evidence that the profession was unwilling to accept any scheme of compulsory health insurance or to invite the government to impose a general scheme of State Medicine upon us. The position we hold is not based upon political or emotional conceptions, but upon a comparative analysis and comparative studies of what we have in the way of delivering medical care to the financially underprivileged, with what is contemplated by measures that are soon to be placed before us for acceptance.

Apparently speaking as an Administra-

tion spokesman, United States Senator J Hamilton Lewis came before the A M A House of Delegates and invited consideration of a scheme of Federal State Medicine applicable to those of the public who are already government wards under the Social Security Law. Since then, irrespective of any comments or critiques of his proposals from the profession, the Senator has introduced as an amendment to the Social Security Law, a Federal medical scheme *not limited to the government wards under the present Social Security Law*, but applicable to the public generally. This scheme while introduced for its educational and propaganda value seems not to have much legislative support.

Meanwhile, reports coming from Washington seem to indicate that compulsory health insurance holds an important place on the legislative agenda of some Administration circles. This is both disturbing and discouraging to organized medicine which has held out its hand in an unequivocal gesture to be helpful in shaping new legislation if such is deemed necessary to bring medical care to the underprivileged and which has taken at its full face value the President's pledge that no drastic change will be made in the American system of practice without

framed and exhibited in a nearby church house, the St Mark's In The Bouwerie, and there was some beautiful comment in the press, did the parents believe that my praise was genuine

I encouraged the child to continue her work. I had her spend several hours daily in my house, in the company of my own child and of a few other children, with full freedom to do as she liked and, of course, without correcting their work in any way. Now the little artist had drawing and painting material at her full disposal.

Then came other events.

I sent one of her splendid drawings to a magazine and it was published, if I am not mistaken, on the front page.

I brought her and her work to Robert Henri, the celebrated painter who was my friend and he became her admirer. He was just then trying to gather nine other artists beside himself in order to exhibit

together with them at the MacDowell Gallery in New York. He had already his own pupil, George Bellows, who had achieved great fame, and some other well-known names. This seven-year old child was added and another, somewhat older one, a little boy with the name Burk, who was destined to become, in later years, a well-known cartoonist.

How I succeeded in getting a scholarship for her in an art school and what she did in her further career is another story which does not differ from the usual biography of professional artists.

What is interesting is that parents do not always recognize their children's gifts. It is in their hands to make them or break them. Also the humility of the parents belonging to the working class.

Although all children draw, most are swallowed by mediocrity in the future, when older. But, all should have a chance.

The Shadow

A South American woman had divorced her husband to whom she had been deeply attached and to whom she had given a child. He had become a drunkard and was not supporting the family.

Her second husband, with whom she had no offspring, was younger than herself and quite sober, but was more interested in his business than in sex intercourse. He was an expert in dresses and the first time he saw her undressed he mumbled "thirty-eight," a remark that gave her a thrill because she was several years older. But when she asked him "How old do you say I am?" he replied "I didn't speak about your age, but about the size of your waistline."

From then on she hated him.

On the one hand she was constantly afraid that this comparatively young man would leave her. On the other hand she was haunted by a terrible remorse concerning her first husband and by a desire to see him again, which she vainly tried to chase. Whenever she had relations with her spouse, which was not often, the image of her old love interposed itself between her and him. It was the feeling described by Zola in his famous *Therese Raquin*, in a reversed fashion. Instead of hating the delusion and being horrified by it our patient was thrilled with delight. She would close her eyes and see the other one, feel the arms, the chest, the body of her former husband. And she

fondled and kissed with such frenzy that her present partner was bewildered and returned the caresses with more excitement than he would have shown under ordinary circumstances and if left to his own unprimed feelings. She lay there thinking of happy scenes and pictures from her intimate life with her first mate. And now she disregarded his drunkenness and even the blows she used to receive once in a while which he regretted when not intoxicated.

She began her story with the words

"I have a bad gallbladder and a bad husband. Excuse me, I meant to say a good husband, a too-good one. I am rather bad. I am not coming for the gallbladder."

As the years passed she sank deeper and deeper into mental depression and self-accusation. Gradually hallucinations developed which tormented her and from which she could not escape. In the course of time she became certain that a definite shadow followed her—her first husband's shadow. She would have liked to be able to roll it up, tie it and put it away—much as it is done in the story by Chamisso, the celebrated French-German poet, I would add.

She was cured by a separation from her second husband, even though she never met the first one again and had to live alone with her daughter for the rest of her life.

EDITORIALS

On Guard!

There was intense professional consciousness of the threat to high quality medical care prevalent among us in the Spring. Due to the summer vacation and the quiet that has resulted from the recess of the legislatures, and the paucity of articles on this topic in the news columns of both lay and medical press, this consciousness seems to have abated somewhat, and we fear the profession is lulled into a feeling that the issue is past.

The discussions and clarifying conceptions which emanated from the last meeting of our House of Delegates would, it seems to us, have been indicators of competent medical opinion. The reports of the A M A session gave additional evidence that the profession was unwilling to accept any scheme of compulsory health insurance or to *invite* the government to impose a general scheme of State Medicine upon us. The position we hold is not based upon political or emotional conceptions, but upon a comparative analysis and comparative studies of what we have in the way of delivering medical care to the financially underprivileged, with what is contemplated by measures that are soon to be placed before us for acceptance.

Apparently speaking as an Administra-

tion spokesman, United States Senator J Hamilton Lewis came before the A M A House of Delegates and invited consideration of a scheme of Federal State Medicine applicable to those of the public who are already government wards under the Social Security Law. Since then, irrespective of any comments or critiques of his proposals from the profession, the Senator has introduced as an amendment to the Social Security Law, a Federal medical scheme *not limited to the government wards under the present Social Security Law*, but applicable to the public generally. This scheme while introduced for its educational and propaganda value seems not to have much legislative support.

Meanwhile, reports coming from Washington seem to indicate that compulsory health insurance holds an important place on the legislative agenda of some Administration circles. This is both disturbing and discouraging to organized medicine which has held out its hand in an unequivocal gesture to be helpful in shaping new legislation if such is deemed necessary to bring medical care to the underprivileged and which has taken at its full face value the President's pledge that no drastic change will be made in the American system of practice without

consultation with the medical profession

Such consultation implies more than a discussion by the profession of an Administration preconceived plan, or a debate on the announcement of a predetermined course. It implies a detailed discussion by Administration authorities on the one hand and representatives of American medicine on the other—to the end that a mutually acceptable plan be formulated by both groups *together* after discussion, and then presented to the general public and to the profession.

In this state Robert F. Wagner, Jr., is a candidate for the State Legislature on an announced platform to sponsor a compulsory health insurance bill in this state, and he is alleged to have already drafted it. While in Washington, his father, United States Senator Robert F. Wagner, is reported as planning a national drive for compulsory health insurance as a further development of the Social Security Law.

It is not our purpose here to argue any part of these proposals, but it is our purpose to put these indicators of the trends in public affairs before the profession for their serious consideration, and thoughtful efforts to protect the *high quality of medical care* which American medicine has evolved and protect it from the devastating influences which these proposals, if enacted into the law, will bring upon it.

Preventing Tuberculosis

Reduced mortality rates tend to lull the public into a false sense of security with respect to tuberculosis. As Dr. Charles H. Goodrich stated in an address before the Sixth District Branch of the Medical Society of the State of New York last month, fewer deaths do not necessarily indicate lower incidence. The large number of persistent cases should dispel spurious hopes that tuberculosis has been conquered. Prevention and early detection of this disease remain one of the primary tasks of modern medicine.

The physician's role in the prevention

of tuberculosis is essentially educational. He must instruct the public in the elements of hygienic living even though conditions beyond his control conspire to deprive many people of them. In private practice, before clubs and civic agencies, he must preach the doctrine of prevention in the hope that at least part of the seed will fall on fallow ground.

Parents' and teachers' associations are eager for knowledge which would help them to fight tuberculosis. Persuade them of the need for tracing and studying all possible contacts in newly discovered infections and prophylaxis will be immeasurably advanced. The same is true of workers' clubs, which are becoming increasingly health conscious and amenable to suggestions for the check of infectious disease in their ranks.

For practical purposes, the early detection and proper treatment of new lesions are inseparable from prevention. The results of organized activity are most striking in this field. The city of Detroit has shown that it is possible to combine the resources of health departments, private medical practice, and social welfare agencies in a drive on tuberculosis along these lines at relatively small cost.

The "Detroit Plan" for tuberculosis does not differ essentially from its anti-diphtheria campaigns. Suspicious cases discovered in the schools and elsewhere are referred to their family physicians for physical examination, tuberculin test, and x-ray. Well-to-do persons pay the regular fees for these services, poorer patients are examined at special rates, and the county pays a minimum fee for indigents. All known contacts are investigated and cases are hospitalized early. Wherever these or similar methods have been employed, the initial outlay for extra hospital beds has paid substantial dividends in early cures and ultimate reduction of the hospital load.

Besides humanitarian considerations, the social and economic consequences of tuberculosis reinforce the demand for a vigorous, permanent program of prevention. Any such project must embrace

public education in prophylaxis, prompt utilization of the best diagnostic and therapeutic methods by physicians, and friendly cooperation between the private practitioner and public health agencies

Fooling the Taxpayer

One of the most dangerous delusions disseminated by politicians in recent years is that the rich are paying and will continue to pay for relief, social security, and various other welfare projects launched by the government. Direct taxation tells only a small part of the story of governmental finance. By far the greatest part of all taxes is passed on to consumers (preponderantly small wage earners) in the form of concealed taxation and higher living costs. So far the country has "charged" its welfare program. When the time comes to pay, it will not be the DuPonts and Morgans who foot the bill, but the white collar man and his brother in overalls.

Like most schemes that promise something for nothing or next to it, compulsory sickness insurance is a vicious hoax, with the joke on those it purports to benefit. Instead of the promised "complete health service," its victims receive a limited amount of perfunctory care, the inferior quality of which is soon reflected in higher mortality and morbidity rates. Prevention lags, diagnosis is hasty and superficial, and therapy takes the form of standardized prescribing.

Let no one think that this inherently cheap service is cheap in price. Besides the regular weekly deduction from his wages, the worker pays the employer's share in higher commodities' costs and the government's contribution in a host of hidden taxes. A large class of employees pay without being eligible for any returns at all.

If the American worker could see panel practice in operation he would soon realize that its only beneficiaries are the political parasites who profit by every extension of bureaucracy in government. Compul-

sory sickness insurance is a game of political blind man's bluff in which the taxpayer (i.e., the worker) is always "it"

More About Sulfanilamide

As the use of sulfanilamide continues to spread, there is noted a corresponding increase in the number of untoward reactions encountered. True, none of these thus far observed has been of such serious import as to endanger life. Nevertheless, it is becoming more apparent that the administration of this drug must be attended by the close clinical observation of the experienced physician and we feel it incumbent upon us to call these side reactions to the attention of the profession as they are reported.

The mildest of the latest recorded reactions are urticarial lesions limited in distribution.¹ These are found upon areas of the skin which have been exposed to the sunlight for a short time. Longer exposure results in a progression in the severity of the lesion which then assumes the form of macular plaques that soon become confluent and result in a maroon-colored eruption.² Maculopapular eruptions have also been described and hemorrhagic spots have been noted.³ What apparently was a definite anaphylactic reaction following the use of sulfanilamide in a nonallergic person is reported by Salvin.⁴

Fortunately, all of these conditions rapidly disappear when the drug is discontinued. We do know, however, that it is essential to recognize the toxic manifestations attendant upon its use. At present, we can summarize these as photosensitization of the skin, the production of methemoglobin, the production of hemolytic anemia, and gastrointestinal symptoms which may result. Neurological manifestations have been noted and its

use in conjunction with any sulphate is distinctly contraindicated.

Eventually, the pharmacology of this chemical will be completely known, but until then, the scattered reports of its use and effects must be studied and given due consideration.

Immunity to Gas Gangrene

The ravages of the Welch bacillus are evident in all walks of life. The child-bearing woman, the farm laborer, the professional motorcar racer—even the patient in the sterile operating field—all are in constant danger of infection from this deadly organism.

It is encouraging therefore, that Penfold and Tolhurst¹ have been able to produce an effective immunity against the *Bacillus Welchii* in animals. Using formal toxoids of the organism which had first been rendered atoxic for mice, they achieved immunity in all their experimental animals. This immunity has been demonstrated to be both active and passive. Their research was primarily conducted to determine whether it was possible to immunize humans with the use of formal toxoids, but this phase of the work is not as yet completed.

If this should prove of value in rendering humans safe from gas bacillus infections, a new field of prophylaxis would be opened. The serum therapy of Welch infections would then largely be supplanted by preventive measures just as diphtheria immunization has almost replaced the extensive use of antitoxin formerly required. We await their further reports with interest.

CURRENT COMMENT

"EVERYWHERE THE MOVEMENTS WHICH BID for men's allegiance are hostile to the movements in which men struggled to be free. The programs of reform are every-

where at odds with the liberal tradition. Men are asked to choose between security and liberty. To improve their fortunes they are told that they must renounce their rights. To escape from want they must enter a prison. To regularize their work they must be regimented. To obtain greater equality they must have less freedom. To have national solidarity they must oppress the dissenters. To enhance their dignity they must lick the boots of tyrants. To realize the promise of science they must destroy free inquiry. To promote the truth they must not let it be examined.

"These choices are intolerable. Yet these are the choices offered by the influential doctrinaires of the contemporary world. Thus those who would be loyal to the achievements of the past are in general disposed to be fatalistically complacent about the present and those who have plans for the future are prepared to disown the heroic past."—A quotation from "The Good Society," a new book by Walter Lippmann. In *The New York Times Book Review* also, we found an interesting commentary on it by Harry Hazlit from which we quote in part "It is governmental coercion he (Mr. Lippmann) contends that is creating the very chaos it purports to conquer. He insists that a managed economy must only mean a censored and managed opinion. He dismisses a planned production to meet a free demand as a contradiction in terms. He ridicules the assumption that there are available omniscient and lovable autocrats to carry out the economic planning. He maintains that such planning is not properly possible except under a military State and for military purposes."—We are inclined to agree with Mr. Lippmann's contentions, and also with the summation of the paradoxical situation which confronts most of us, his opinions on which we have quoted above.

"WE HAVE RENOUNCED THE WISDOM of the ages to embrace the errors the ages have discarded. The road whereby mankind has advanced in knowledge, in the mastery of nature, in unity, and in personal security, has lain through a progressive emancipation from the bondage of authority, monopoly and special privilege. It has been through the release of human energy that men have lifted themselves above the primeval struggle for the bare necessities of existence, it has been by the removal of constraints that they have been able to adapt themselves to the life of great societies, it has been by the disestablishment of privilege that men have risen from the status of slaves, serfs and subjects to that of free men inviolate in the ways of the spirit."—*The New York*

Herald Tribune of September 26 quotes the above from Mr Lippmann's book, and we find it well worth quoting also

"GREAT BRITAIN NEXT THURSDAY begins a campaign for health and physical fitness without parallel in the history of the nation. More than ordinary interest is attached to this health drive. There is the coincidence that it comes at the same time as Great Britain's extensive rearmament program. It has been loudly proclaimed, including statements in the House of Commons, that the coincidence is entirely accidental"—An Associated Press item of interest in *The New York Herald Tribune* of September 26

"BEGINNINGS OF STATE MEDICAL SERVICE in Australia" are described in the *JAMA* of September 25 by its regular correspondent. "With the aim of providing all people, irrespective of the locality in which they are situated or their financial position, with the best medical attention and hospital accommodation when necessary with adequate supervision from a public health point of view, the government of Tasmania is appointing ten physicians who will be attached to the staff of the department of health. The most important duty of the medical officers will be to attend the sick and injured in their respective districts. Preventive medicine will also receive attention, and the duties of medical officers of health will devolve on the new appointees. They will enforce the public health regulations regarding sanitation, dairying, milk supplies, the isolation and treatment of infectious diseases and the control of quarantine. Provision for study leave is included in the terms of appointment. Medicines will be

supplied from a central dispensary with depots in each district"

"THE PHYSICIAN SHOULD HAVE A definite point of view on war which need have nothing to do with sentiment or emotional reactions. It seems to us that any kind of a war is not in keeping with the philosophy of the medical man. The medical man goes to a lot of trouble getting an education. He has to learn many things of a cultural nature that have nothing to do with medicine, and then he has to learn a lot of things both in theory and practice on how to heal people and prolong life. This does not seem to be in keeping with the ambitions and policies of those who make war. From all the information we can gather warfare tends to kill and cripple. That much property is destroyed in this attempt to annihilate and kill, we realize but we do not feel at the moment that this is our problem"—'It Is So Discouraging' claims a timely editorial in the *Medical Record* of September 15, from which we have quoted in part

"THE GROWTH OF SCIENTIFIC KNOWLEDGE has multiplied the number of things that can be done to prevent and cure disease, but it has also increased the cost of medical service, putting it beyond the reach of an ever-growing number of people

"Modern society everywhere accepts as an obligation the provision of the necessities of life for those who cannot provide for themselves. I don't think that any one will deny that medical service is a necessity of life, and it is only a small step from that to the fact that such service may be made available by the community to those in need"—The words of Dr Thomas Parran, Surgeon General United States Public Health Service in the *New York Times Magazine* of September 26

THE REWARDS OF MEDICINE

Medicine is a path to fortune only for the few. Yet if from the financial point of view medical practice offers to most men little more than a means of livelihood, in its social and cultural aspects the outlook is far brighter. A doctor's life need yield to none in the matter of sustained and varied interest, we read in *The British Medical Journal*. His lot is unlike that of many whose business gives little scope to the higher faculties for he lives in, and by, the exercise of intellectual powers. Gradual im-

provement in the education of the practitioner has added much to his influence with the public and has been a large factor in raising his social status. Medicine gives to those who follow it an honorable position. The well-educated doctor stands high among his neighbors, and is the friend and confidant of his patients. Many go further, and take part in the public life of their district and this is as it should be, because the doctor's training and outlook are such as fit a man for leadership.

use in conjunction with any sulphate is distinctly contraindicated.

Eventually, the pharmacology of this chemical will be completely known, but until then, the scattered reports of its use and effects must be studied and given due consideration.

Immunity to Gas Gangrene

The ravages of the Welch bacillus are evident in all walks of life. The child-bearing woman, the farm laborer, the professional motorcar racer—even the patient in the sterile operating field—all are in constant danger of infection from this deadly organism.

It is encouraging, therefore, that Penfold and Tolhurst¹ have been able to produce an effective immunity against the Bacillus Welchii in animals. Using formal toxoids of the organism which had first been rendered atoxic for mice, they achieved immunity in all their experimental animals. This immunity has been demonstrated to be both active and passive. Their research was primarily conducted to determine whether it was possible to immunize humans with the use of formal toxoids, but this phase of the work is not as yet completed.

If this should prove of value in rendering humans safe from gas bacillus infections, a new field of prophylaxis would be opened. The serum therapy of Welch infections would then largely be supplanted by preventive measures just as diphtheria immunization has almost replaced the extensive use of antitoxin formerly required. We await their further reports with interest.

CURRENT COMMENT

"EVERYWHERE THE MOVEMENTS WHICH BID for men's allegiance are hostile to the movements in which men struggled to be free. The programs of reform are every-

where at odds with the liberal tradition. Men are asked to choose between security and liberty. To improve their fortunes they are told that they must renounce their rights. To escape from want they must enter a prison. To regularize their work they must be regimented. To obtain greater equality they must have less freedom. To have national solidarity they must oppress the dissenters. To enhance their dignity they must lick the boots of tyrants. To realize the promise of science they must destroy free inquiry. To promote the truth they must not let it be examined.

"These choices are intolerable. Yet these are the choices offered by the influential doctrinaires of the contemporary world. Thus those who would be loyal to the achievements of the past are in general disposed to be fatalistically complacent about the present, and those who have plans for the future are prepared to disown the heroic past."—A quotation from "The Good Society," a new book by Walter Lippmann. In *The New York Times Book Review* also, we found an interesting commentary on it by Harry Hazlit, from which we quote in part: "It is governmental coercion he (Mr. Lippmann) contends that is creating the very chaos it purports to conquer. He insists that a managed economy must only mean a censored and managed opinion. He dismisses a planned production to meet a free demand as a contradiction in terms. He ridicules the assumption that there are available omniscient and lovable autocrats to carry out the economic planning. He maintains that such planning is not properly possible except under a military State and for military purposes."—We are inclined to agree with Mr. Lippmann's contentions, and also with the summation of the paradoxical situation which confronts most of us, his opinions on which we have quoted above.

"WE HAVE RENOUNCED THE WISDOM of the ages to embrace the errors the ages have discarded. The road whereby mankind has advanced in knowledge, in the mastery of nature, in unity, and in personal security, has lain through a progressive emancipation from the bondage of authority, monopoly and special privilege. Committee on Workmen's Compensation

STATE OF NEW YORK
DEPARTMENT OF LABOR
ALBANY

New York Office 80 Centre Street

New York
Sept 16, 1937

Dr David J Kaliski, Chairman
Workmens Compensation Board,
New York County Medical Society,
2 East 103 Street,
New York City

Dear Doctor Kaliski

In order to eliminate confusion at hearings on compensation claims which has existed, as to who was responsible for the payment of fees to physicians who are engaged by claimants merely to appear and testify on their behalf, the following rule has been promulgated (Rule No 21-A)

A physician who testifies at hearings or examines claimants or participates in examination for evidential material for compensation case hearing purposes only, may accept fees for such services from claimants

In order to clear up some confusion which has existed in the payment of hospital bills that included services rendered by salaried physicians on the hospital staff, rule No 22 has been amended and revised to read as follows

Hospitals shall render bills for Board and room accommodation, medical and surgical supplies and nursing facilities. Hospitals may render bills for x-ray physiotherapeutic, anaesthesia and pathologic services when rendered by or under the supervision of salaried physicians on the staff. The names and qualifications of all physicians and persons rendering service for which charges are made by hospitals must be included in all bills and all medical and x-ray reports shall be promptly filed with the employer or its insurance carrier and the Department of Labor

I am referring these matters to you for your information and dissemination

Yours very truly,

(signed) ELMER F ANDREWS,
Industrial Commissioner

Public Health News

Transiency—A Public Health Menace

Eradication of tuberculosis as a human epidemic can be brought about only through methods of precision. Recognizing the open case is highly important but it is not enough. Already that case has done his bit to keep the epidemic alive by spreading his disease to others. No passive measures will suffice. An aggressive hunt for the occult spreader is essential. To be productive, the search must be directed to those groups showing high rates of infection. One of these groups is our increasing army of transients

At least one type of citizen in the United States stubbornly defies regimentation, classification, or control. He is the tuberculous transient who has come west seeking a climatic cure, exhausted his resources and now wanders from place to place on foot, on brake rods, or in a dilapidated auto. In jungles, shacks and flophouses he pauses when he must. He has lost his claim as a resident of the home town he deserted, and is not welcomed as a resident elsewhere, since he is regarded as a "bum" without visible means of support, but with a very visible need of relief. He is not, in the main, getting well of his consumption

—salubrious climate notwithstanding. In many instances he is accompanied by his worried wife and half-starved children. Worst of all he is a prolific sower of the seed that causes tuberculosis, for even the respectable, cautious resident cannot escape contact with him directly or indirectly at the filling station, restaurant, tourist camp or lodging-house.

No census has been taken of tuberculous wanderers, but a conservative estimate, based on observations of transient officers, is that their number exceeds 1,000 in the states of Colorado, Arizona, New Mexico, western Texas and southern California. This number, however, includes only the obvious consumptives—obvious, that is, to the non-medical social worker. If a more

Reprinted by permission of *Tuberculosis Abstracts*, October 1937

thorough and precise case-finding search were made, including X-ray examinations, the army of indigent tuberculous in the Southwest would doubtless exceed 5,000.

Sooner or later these wanderers will lose their legal residence acquired in the communities whence they came and very many of them will not gain citizenship in a new locality. Opportunities to earn a livelihood are scanty or non-existent. Indigence is added to their invalidism and with no settled residence they are nobody's responsibility. This is calamity enough for the unfortunate victim, but it is very bad in another sense. In his extremity the patient moves on, perhaps crossing state boundaries, but surely spreading his disease in the new regions he visits in the hope of finding some relief.

The recent business depression has noticeably aggravated the problem of the migrant tuberculous. Failure to make a living at home has started a vast number of new transients on the road, many known and occult cases of tuberculosis among them. At the same time state and community resources for public health and welfare work have dwindled.

Recognizing the gravity of this situation the National Tuberculosis Association called a conference last year at Santa Fe to which public health and welfare workers from the Southwestern States were invited. The conclusion reached was that the problem was too great for solution locally and the recommendation was made that organized federal aid be requested.

Already the Emergency Relief Administration has provided its transient shelters, hastily constructed concentration camps set up in an effort to "freeze" the army of aimless wanderers. Provision was made for those who were ill, and of this number about a third were found to be suffering from tuberculosis. These were segregated and heroic service was rendered by local doctors and all available nurses working under serious limitation because of inadequate room and equipment.

Hard times will always emphasize the problem of the sick indigent, homeless transient, but the problem itself antedates hard times and will persist through prosperous ones as well. The menacing public health aspects of the situation are still to be faced. The medical profession can render incalculable aid toward lessening this evil by damming up the transient stream at its source. The advantages of certain climates in the treatment of pulmonary disease are readily admitted. But climate is only one of the essentials in recovery from pulmonary tuberculosis and by no means

the most important. Comfortable living, with rest, peace of mind, adequate nutrition and skilled medical care are the prior requisites. If physicians will preach these doctrines in their communities as well as to their patients the melancholy hegira of unsuitable cases will diminish. If they will with insistence point out the increasing provision of excellent sanatoria near at hand in their own localities, at the same time demonstrating the growing percentage of arrested cases discharged from these institutions, they will make a contribution to public health protection of genuine significance.

But the tide will recede slowly and meanwhile there is the army already enlisted in this great migration. How to prevent its continuing to spread disease is a question that is perplexing the most experienced health and social workers. Forcible detention is in bad odor—tuberculosis is not yet regarded by the public as seriously as leprosy for example. Deportation to point of origin would not solve the larger problem and for some patients who have the fixed idea that their very lives depend upon living in this or that climate, it would be inhumanly cruel to send them home, wrong though they might be. To erect sanatoria in resort areas would result in luring persons from all parts of the country, and thus aggravate the evil. Families would come with them and, not being eligible as patients, would be dumped upon the mercy of social agencies in cities and towns nearby, already swamped with appeals from their own people.

One proposal made is that colonies be established in the great open spaces for entire families. But the states where they would be most likely to settle are least able to support such an enterprise and the federal government can hardly be expected to finance it, at least not until the broad problem of transiency is tackled through sweeping legislation such as that proposed in the Trammell-Wilcox bill recently before Congress. Self-support of such a colony is a fatuous hope and it seems unlikely that many families would consent to be herded together in that manner. And if such colonies, because of good management and by providing attractive living conditions should succeed, we would again be confronted by the problem of preventing the influx of families from all over the country who had better remain where they are.

At present the United States Public Health Service is studying the situation to see what facilities are available. The situation is probably not as hopeless as it might have been a few years ago. One advantage

is that the country generally is now better equipped to care for its tuberculosis residents near at home. Another advantage not to be had a few years ago are modern weapons that are now used to combat tuberculosis. Isolation of the carriers in sanatoria is, of course, the crux of the situation, but there are also new developments in diagnosis and treatment which make the control of tuberculous transients, even in the absence of adequate beds, more workable than some years ago. For example, collapse surgery enables the otherwise bedridden patient to carry on light work, and this treatment also renders him bacillus-free which means that he promptly ceases to be a danger to others. Fifty per cent or more of all tuberculous patients can be successfully "collapsed," and so-called ambulatory pneu-

mothorax treatment is now an accepted procedure. There are furthermore better methods of case-finding. It would not be Utopian to propose that all transients be X-rayed, which would lead to the discovery not only of obvious cases, but also of those in the earlier stages who by prompt action could soon be restored to health.

"No home is safe until every home is safe," is an old slogan used by tuberculosis associations. Until we have come to grips with the tuberculous transient, we cannot hope to guarantee safety to the rest of American citizens.

Drs Van Volkenburgh and Stebbins Promoted

V. A. Van Volkenburgh, M.D., Dr.P.H., has been promoted to the position of Assistant Commissioner of Local Health Administration, and Ernest L. Stebbins, M.D., to that of Director of Communicable Diseases, effective September 16.

Dr. Van Volkenburgh, formerly Associate in Epidemiology at Johns Hopkins School of Hygiene and Public Health, was appointed on the staff of the New York State Department of Health several years ago and has since served successively as assistant

district health officer, epidemiologist and district health officer. For the past two years he has been in immediate charge of the Ithaca Health District.

Dr. Stebbins joined the Department staff in 1934 having had previous experience as assistant epidemiologist with the Virginia State Board of Health and as health officer of Henrico county, Virginia. Since March 1936 he has been in charge of the Rochester Health District—*Health News*, September 27, 1937.

A WIDER STUDY OF LEPROSY

The Leonard Wood Memorial announces the appointment of Dr. George M. Saunders as director of a department to make a special world-wide study of the environmental factors that affect the lives of lepers and that might assist in treatment. Dr. Saunders is a graduate of the University of Wisconsin and the Harvard Medical School.

In 1931 he headed an expedition to Yucatan to study malaria and amebic dysentery. For the last five years he has been director of the Yaws Commission in the British West Indies under the auspices of the Rockefeller Foundation.

The Memorial believes that nothing that has ever been done in the campaign against leprosy is so promising of results as the program now inaugurated. For several years, epidemiological studies have been carried on under the direction of Dr. Jose Rodriguez at the Memorial's leprosarium

at Cebu in the Philippines, but because leprosy exists in almost all parts of the world and under such differing conditions, it is not sufficient to work in one place only; scientific research should be carried on simultaneously in many places, widely separated to furnish comparative data.

The United States, with considerable leprosy in southern states, Puerto Rico, the Virgin Islands, and Hawaii, is the first country to create its local unit of study. The Public Health Service has appointed Dr. George W. McCoy as director of these studies.

As October 9 was the anniversary of the birth of General Leonard Wood, who was instrumental in starting this work, the Memorial felt that it is especially appropriate to ask all who can do so to help eradicate leprosy through the contribution of the additional funds needed to carry on their enlarged study.

Medical News

Cattaraugus County

DR ERLY HARRISON MADISON, of Olean, who died on September 15, had been City Physician for seventeen years. He would have been seventy on October 29.

Cayuga County

DR. LEO F SIMPSON was the guest speaker at a meeting of the Cayuga County Medical Society on September 16 at Auburn. Doctor Simpson gave an account of his visits during the past summer to hospitals in Norway, Sweden, Denmark, Germany, France, and England and the various methods and practices of physicians in those countries. Dr Donald Green presided.

Chautauqua County

THE ANNUAL FALL MEETING of the Chautauqua County Medical Society was held September 15 at Newton Memorial Hospital at Cassadaga, where the members were guests of the board of managers at dinner. A business and scientific session was held during the afternoon. Dr Werner J Rose gave a paper on "Conditions Above and Below the Diaphragm that Simulate Heart Disease." Dr W G Hayward is president of the county society, the other officers being Vice-president, Dr C E Hallenbeck, secretary, Dr Edgar Bieber, treasurer, Dr Frederick J Pfisterer.

DR. WARREN D WELLMAN, one of Jamestown's oldest practicing physicians, died on September 18, aged eighty-two. He had practiced medicine there forty-nine years.

Cortland County

AN INTERESTING TALK on some of the comparatively rare complications occurring in obstetrics was given before twenty-five members of the Cortland County Medical Society and visiting physicians by Dr Ward L. Ekas, associate professor of gynecology and obstetrics of University of Rochester school of medicine, on September 17. Dr Ekas' subject was "Management of Some Difficult Obstetrical Problems." A general discussion followed the talk which was given at the Cortland Free Library auditorium.

Dutchess County

A SCIENTIFIC DISCUSSION ON "Uterine

Displacements" by Dr Walter T Dannreuther, of the Post Graduate hospital, New York city, was the feature of the regular meeting of the Dutchess County Medical Society in Poughkeepsie on September 8.

Erie County

DESIGNED TO ARM PHYSICIANS to combat attacks on their profession, a comprehensive course in public speaking was launched by the Erie County Medical Society last month.

"Physicians usually are unwilling to express publicly their views concerning repeated attacks on the medical profession," explains Dr Harry C Guess, chairman of the society's educational committee, who arranged the course.

"The purpose of the course is to train them to become highly articulate and more fluent in speech, and to overcome their natural reticence that they may combat the arguments advanced by lay agencies seeking to foist their particular ideas of scientific medicine upon the public."

A score of physicians have signed up for the course, which opened September 23, under the direction of Stanley D Travis, assistant professor of English at University of Buffalo. Classes will be conducted each Thursday until December 2. The course is open to any member of the society.

THIRTEEN STATES AND THE province of Ontario were represented in the registration of thirty-one practicing physicians in the seventeenth annual post-graduate course in medicine and surgery, held at the University of Buffalo School of Medicine in September. The doctors enrolled were graduates of twenty-five different colleges and universities.

Kings County

THE WOMEN'S AUXILIARY TO THE Medical Society of the County of Kings, Mrs Edwin A Griffin, president, gave a bridge on October 6, at the home of Mrs Frederic E Elliott. Mrs Maurice J Dattelbaum was chairman.

THE ASSOCIATION of MILITARY Surgeons of the United States invited Dr William Z Fradkin, of the Jewish Hospital of Brooklyn, to exhibit his work on Colitis and the Diarrheas, at their Annual Convention in Los Angeles, October 14-17. This same exhibit was shown at the A M A Convention in Atlantic City.

THE ASSOCIATION OF MILITARY Surgeons of the United States invited Dr. William Z. Fradkin, of the Jewish Hospital of Brooklyn, to exhibit his work on Colitis and the Diarrheas, at their Annual Convention in Los Angeles, October 14-17. This same exhibit was shown at the A.M.A. Convention in Atlantic City.

Madison County

THE WOMAN'S AUXILIARY OF THE Madison County Medical Society held a dinner meeting at the Hotel Oneida, in Oneida, on September 9. Dr Otto Pfaff spoke.

Monroe County

THE ROCHESTER GROUP OF THE American Association of Medical Social Workers is sponsoring a series of eight weekly Wednesday lectures by physicians on "Social and Emotional Factors of Disease," first of which was given on September 22 in the assembly hall at Rochester General Hospital. The first lecture, on syphilis, was given by Dr John B. Laidlaw, assistant physician in medicine at Strong Memorial Hospital and instructor in medicine at University of Rochester School of Medicine and Dentistry. Other speakers and their subjects include Dr Charles B. F. Gibbs, attending physician, Rochester General Hospital, diabetes; Dr Wesley Pommerehne, assistant obstetrician and gynecologist, Strong Memorial Hospital, diseases of women; Dr W. J. Merle Scott, associate surgeon, Strong Memorial Hospital, cancer; Dr Libby Pulsifer, attending physician, General Hospital, gastrointestinal disorders; Dr William S. McCann, physician-in-chief, Strong Memorial Hospital, degenerative diseases; Dr R. Plato Schwartz, associate surgeon, Strong Memorial Hospital, orthopedic conditions; Dr Albert D. Kaiser, chief of pediatric service, General Hospital, diseases of children.

MORE THAN 600 PHYSICIANS of the city and county were guests of the officers and trustees of the Rochester Academy of Medicine at a dinner meeting in the Chamber of Commerce on September 9.

Dr Perrin H. Long, associate professor of medicine, Johns Hopkins Medical School, spoke.

Nassau County

DR LOUIS A. VAN KLEECK was guest speaker at a meeting of the woman's auxiliary to the Nassau County Medical Society, on September 21, at the Nassau hospital auditorium, Mineola.

Niagara County

THE NIAGARA COUNTY MEDICAL Society resumed its activities on September 14 with a dinner meeting, attended by seventy-five members. A paper on "Clinical Problems in Gall Bladder Disease," was read by

Dr Robert S. Dinsmore, of the Cleveland Clinic. A discussion was led by Dr James C. Sullivan.

THE NIAGARA COUNTY HOME BUREAU, with the cooperation of the Niagara County Health Association, the Niagara County Medical Society and the District Health Department of Buffalo, is sponsoring an educational campaign against pneumonia. Information will be given on "what pneumonia is" and "why it is a public health problem" to lay leaders from Home Bureau groups and any other interested community organizations at a training institute to be held October 29 by Dr Edward A. Rogers, director of the Bureau of Pneumonia Control, Albany.

Oneida County

THE UTICA ACADEMY OF MEDICINE speaker for the October 21 meeting will be Dr B. R. Kirklin of the Mayo Clinic. He will read a paper on "Gastrointestinal Diseases," which last year he presented to the Royal Society of Medicine in London.

THE ANNUAL DINNER MEETING and golf tournament for members of the Syracuse and Utica Academies of Medicine was held at the Yalmundasis Country Club, Utica, on September 16. The event has been held annually ten or twelve years, with Utica and Syracuse alternating as host. The dinner was followed by a scientific program. Dr Leon E. Sutton was guest speaker and the department of anesthesia of the College of Medicine, Syracuse University, gave "A Consideration of the Newer Developments of Anesthesia."

Onondaga County

A BOOTH FOR THE DISTRIBUTION of literature and for discussions on maternal welfare at the New York State fair was under the supervision of members of the woman's auxiliary to the Onondaga County Medical Society. A nurse and two women were in attendance each day of the fair. Miss Mary McGarry, district state supervising nurse, assisted the members of the auxiliary in arranging the booth.

Ontario County

VETERANS HOSPITAL STAFF members were hosts on September 9 to members and guests of the Canandaigua Medical Society at a meeting on the reservation. A chicken dinner was followed by a program by the hospital staff. Dr Hans Hansen, manager, read a paper on "The General Aspects of

the Treatment of Dementia Praecox by Means of Insulin Shock," after which the following staff members conducted clinics: Dr Louis V Lopez, on "Encephalitis," Dr Johnnie A Norris, "Neurosyphilis," and Dr Victor Goodside, "Chorea."

Dr A W Armstrong was host at a regular meeting of the Society October 14, with Dr J H Pratt as speaker

Oswego County

THE ONE HUNDRED AND SIXTEENTH ANNIVERSARY of the Medical Society of Oswego County was celebrated on October 14 at Oswego. The speakers were Dr Charles H Goodrich, President of the Medical Society of the State of New York—subject, "Preventive Medicine"—and Dr Norris Fishbein, Editor of the *Journal* of the American Medical Association—subject, "Medicine and The National Policies"

Queens County

DR J ARTHUR MYERS of Minneapolis, president of the National Tuberculosis Association praised the Queens plan to check tuberculosis, in an address on September 22, at the eighteenth annual meeting of the Queensboro Tuberculosis and Health Association, held with the Queens County Medical Association

"The Queens plan, about to be launched, to offer x-rays of the chest to the apparently well adult population for \$1 each by the rapid x-ray method," he said, "is one of, if not the very best, modern methods for discovering the many unknown cases of tuberculosis that are constantly spreading the disease."

At the meeting Dr Carl Boettiger was elected president, Dr George F Ryan, first vice-president, Mrs D W Thompson, second vice-president, and Harry V Hoyt, treasurer

Dr James J Reuling, president of the Queens County Medical Society, had explained that the society and the association would begin an extensive campaign soon to find the unknown cases of tuberculosis in the borough by offering x-rays of the chest with report of the findings for \$1 each

"This," he said, "will be another instance where the Borough of Queens has led the way in inaugurating a health project of far-reaching value in making this borough of ours a healthier and happier place in which to live."

THE QUEENS COUNTY CANCER Committee has announced the formation of a speakers' bureau for the 1937-1938 season

The following physicians, all members of

the Queens County Medical Society, have been appointed to the speakers' bureau

Dr Carl Boettiger, Dr William T Hoffman, Dr Ida Mintzer, Dr Irving Ponemon, Dr Francis G Riley, Dr Joseph S Thomas, Dr Albert L Voltz and Dr Joseph Wrana

The bureau sends out speakers to social, fraternal, political, school and church groups, whenever a request for such service is made

The Cancer Committee, in a statement said

We urge organizations throughout the borough to take advantage of our free speakers' service. We will be more than glad to send an interesting speaker on the topic of cancer to any group that communicates such a request to us"

St Lawrence County

DR D M MILLS AND HIS SON, Dr H L Mills won the championship in the fifth annual Northern New York Father and Son Golf tournament at the Jefferson County Golf Club on September 19. The pair turned in the low net score 83. They had a gross score of 95

DR F F WILLIAMS, eighty-year-old Canton physician, was named health officer of the village by the village board on September 13

Steuben County

THE STEUBEN COUNTY MEDICAL Society met in Hornell on September 9. Papers given were as follows: "New Uses of Oxygen," by Dr Clarence Durshordwe, "Surgery for Immediate Dentures," by Dr Amos G Stiker

Westchester County

DR MATTHIAS NICOLL, JR, Commissioner of the Westchester County Department of Health since 1930, will retire in the Spring, he announced on September 9. Dr Nicoll, former State Health Commissioner, will reach the age limit set by the State some time during next year. Announcement of Dr Nicoll's retirement comes on the heels of the retirement of Dr Richard Slee, First Deputy Health Commissioner, who left the department October 1. Dr Nicoll as State Commissioner, appointed Dr Slee District Health Officer for this part of the State before the County Department was set up

DR ALEXANDER O SNOWDEN, a practicing physician in Peekskill for nearly sixty years and the oldest physician there, died at his home on September 20, of a heart attack. He was in his eighty-fourth year

Hospital News

Should Interns Be Paid?

IT HAS RECENTLY BEEN POINTED OUT that 2,685 of the 6,923 interns in the United States, or more than one-third, receive no remuneration from the hospitals they serve other than board and lodging, and that the average cash allowance of the others was \$25.88 a month. In recent years there has been considerable agitation for a more adequate financial arrangement. Many questions are involved, says *The Medical Record*. Should interns be paid at all? If so, should their wage be commensurate with their professional status? Should they accept gifts of money from patients, or from attending physicians for some special services rendered? Or, as has been facetiously suggested, in view of the great rivalry for favorable positions in preferred hospitals, should not internships be auctioned off to the highest bidders?

One thing surely can be said in favor of paying interns. They will know the luxury, for a year or two, of financial independence. For a long time after leaving their well-protected intramural practice to climb the hills of private work, they will never feel as secure. The previous years of study and expense surely were trying enough. Who, then, would gainsay the poor intern his fleeting breathing spell, his temporary Arcadia, the busy, delectable days spent in seeing cases rather than

reading about them in books, and actually receiving cash for the privilege?

Of course the intern should be paid, declares *The Medical Record*. His professional pride calls for money in his pocket, money which he has earned by hard effort, by conscientious and servile attention to duty, by sleepless nights, by abuse as underdog from his betters. What if he does presume too much at times, in assuming a superior attitude towards his attending physician by flaunting his newly-won knowledge? What if occasionally a touch of superciliousness and brusqueness creeps into his manners? He is going through a trial by fire, he is being given authority in a heap, and he is learning to adjust himself to his new powers. Time will tame him, but for the present a superabundance of energy and a latent mass of power must expend itself, to the discomfiture of training school office, and the annoyance of staff physicians. When he has put off his white uniform for the last time, and his mind is on favorable locations, there will be more than a touch of tenderness throughout the hospital as he makes his final round of farewells.

He will be given his godspeed with tenderness and sincere regrets. What is more, if he is a paid intern, he may have his first month's rent in his pocket.

Unqualified Surgeons Barred Out

FOR THE FIRST TIME in its history the Cleveland Hospital Council has adopted mandatory regulations upon its member hospitals, we are told in *The Modern Hospital*. To safeguard surgical patients, a committee under the chairmanship of Dr. George E. Follansbee, president of the council, prepared the following minimum standards of qualification to practice major surgery:

1. Membership in a recognized local organization of doctors of medicine, the membership of which includes practitioners of both general medicine and the specialties and which has state and national affiliations.

2. Either, (a) two full years of hospital

training, at least one of which shall have been in general surgery in a hospital approved for the training of surgical residents by the American Medical Association (in the case of surgical specialties the training shall have been in a hospital approved for such special resident training by the A. M. A.), or (b) membership on the active visiting surgical staff of a member hospital of the Cleveland Hospital Council and classified to do major surgery, or (c) fellowship in the American College of Surgeons, or (d) not qualifying as above but having had sufficient surgical experience, when certified by a member hospital of the Cleveland Hospital Council that has adopted

these minimum standards, and on recommendation of the surgical authority of that hospital, accompanied by a statement of experience and training justifying the recommendation

The committee believes that the staff as a whole or its designated representatives is the authority best qualified to judge applicants

For the purpose of establishing the minimum standards, "major surgery" has been defined as

1 Operations within or upon the contents of the following cavities cranium, thorax and abdomen, including the pelvis

2 Other operations which, because of locality, condition of the patient, difficulty or length of time required to operate, constitute a distinct hazard to life.

3 In case of doubt or dispute, the surgical authority of the interested hospital shall determine whether an operation is major or minor

The committee recommended that these new regulations should not be retroactive but be put into effect Nov 1, 1936, and should govern all applicants from that date.

The committee further recommended that the classification of member hospitals be

restricted to those hospitals which meet present requirements and agree to adopt and maintain recommended standards for the practice of major surgery

In promulgating the standards, the committee stressed the fact that the standards were minimal and that any hospital could establish for itself a higher standard but no hospital "agreeing to cooperate may establish a lower standard"

The committee also stated that "an applicant having been approved to practice major surgery in a certain hospital has no right because of such approval to demand permission to practice major surgery in another hospital, whether with a higher or a lower standard. No hospital is obligated to accept an applicant because of the fact that he has qualifications herein set forth, but each hospital shall be its own judge within the restrictions herein set forth. Classification to practice major surgery in a hospital is revocable at any time at the discretion of the surgical authority of that hospital"

The council hopes, by these measures, to afford reasonable protection of patients against inefficient and inadvisable operation, to protect the reputation of the hospitals and to elevate the practice of major surgery

Liability Insurance

THE ATTENTION OF THE HOSPITAL world was directed recently by an article in *The Modern Hospital* to the necessity and, indeed, the fairness of providing liability insurance for members of the personnel

While it is hardly likely that employees in the lower brackets would ever be held personally responsible for mistakes of their own, this statement does not apply to physicians or even nurses as a group, it remarks in a later editorial. The head of the x-ray or the physical therapy department might easily, through no fault of his own, be accused of responsibility for a burn by x-ray, electrical contact or even for injury from other physical agents employed in the treatment of disease

To be sure, most physicians carry some form of liability insurance. They should, however, examine their policies carefully

to be sure the protection is adequate. There is at least one company, for example, which will defend the head of an x-ray or physical therapy department against suit for damages resulting from a real or supposed injury if he personally were administering the treatment. But this company stipulates that unless all technicians in these departments carry liability insurance it will not defend the head of the department if he is sued for damage resulting from the act of a technician. Were insurance companies generally to adopt this attitude the director of such a department would be in continual jeopardy from malpractice suits

The hospital should adopt a fair position toward the protection of its staff members against the depredations of unscrupulous persons seeking to profit through trumped-up liability suits

Improvements

MOUNT SINAI HOSPITAL (New York City) receives \$916,579 from the estate of

Marco Fleishman, leaf tobacco merchant, who died Feb 17, 1936, according to a

transfer tax appraisal filed recently Mr Fleishman's net estate, according to the appraisal, amounted to \$1,170,482. Under the provisions of Mr Fleishman's will the bequest to the hospital will be known as the Rosetta and Marco Fleishman Fund and will be used for the construction and equipment of a new building or extension of the existing buildings to care for persons suffering from tuberculosis in its early stages.

THE BOARD OF MANAGERS OF IOLA Sanatorium at Rochester has asked the Board of Supervisors to appropriate funds for enlarging the medical wing, housing the dispensary, laboratories, x-ray and surgical departments.

This request has been supported by the Tuberculosis and Health Association, by the Division of Tuberculosis of the State Department of Health, and by the Tuberculosis Subcommittee of the Monroe County Medical Society. The cost is estimated at about \$100,000.

Points particularly stressed are that dispensary facilities would be improved and delays in examinations reduced.

LEONARD HOSPITAL in Troy, has added a complete new x-ray department, costing \$5,000.

WORK ON THE HALF-MILLION DOLLAR addition to Rav Brook State hospital is progressing rapidly with the steel frame of one wing already erected and the foundations of the entire building finished.

A DECISION TO DROP the proposed plans for a fifty-two-bed hospital for Massena at an estimated cost of \$200,000 has been made by the Massena Chamber of Commerce. It was decided to attempt to finance a smaller institution at a cost of \$50,000.

THE NURSES' HOME AT THE Leonard Hospital in Troy, scene of a disastrous fire last winter, has been rebuilt and is now occupied.

A MILLION DOLLARS' WORTH of small, free, "poor-man hospitals" and clinics are being scattered about Louisiana by Governor Richard W. Leche.

"When people are too poor to pay for private medicine and hospitalization they are too poor to travel a long distance, so we are bringing new hospitals to the people," said Governor Leche recently in explaining the program.

"Free hospitalization for the destitute in many states is being conducted on a county or municipal basis, but we believe Louisiana is a pioneer in establishing a state-wide system."

The plan calls for a network of clinics and small five-bed to ten-bed wards in private hospitals under contract to the state. The cost of surgical and medical care, nursing and other services will be defrayed by the state on a fee basis.

THE CORNERSTONE OF New York City's new Welfare Hospital for Chronic Diseases was laid on Oct. 5. It will be the largest hospital in the world devoted exclusively to the scientific care of chronic diseases and will be affiliated with Columbia University's College of Physicians and Surgeons, Cornell University Medical College, and New York University College of Medicine. A carefully selected research staff has now been engaged in important investigations for more than a year and the first fruits of its studies will be made known to the medical profession through scientific journals during the coming winter. Studies are progressing in phases of such chronic diseases as rheumatoid arthritis, cirrhosis of the liver, chronic nephritis, pulmonary emphysema, arteriosclerosis, and hypertension.

Newsy Notes

AN INTERESTING EXPERIMENT is being tried in Oswego, where the doctors ceased caring for relief cases in the Oswego Hospital gratis in October 1936, and demanded that the Welfare Department pay them the same fees as they received in private cases.

Accordingly an allotment of \$6,228 was provided for this purpose for 1937, but by August \$5,595 of it had been expended for doctors' fees, leaving only \$633 to carry through to Jan. 1. The Welfare Department has asked for an additional \$4,000.

X-RAY DUPLICATES FOR THE PATIENT

THE VALUE OF X-ray pictures for diagnostic purposes has long been realized, but aside from its value to the physician it meant very little to the layman.

Some months ago Dr Courtenay I Headland, Director of the Department of Roentgenology of the Yonkers General Hospital conceived the idea of reproducing the X-ray films in miniature photographs for the patient, thereby giving him an accurate picture of the broken bone, the presence of gall stones or other pathological condition. Each patient was therefore presented with these pictures.

This service has proven of value also to the physician, making it unnecessary for him to burden himself with the bulky plates for outside consultation at compensation court etc., though the plates are as always available.

These pictures are only 3 1/4 by 4 1/2, but give accurate details and can be filed by physicians with the patient's record in their office. They may also prove valuable to patients leaving the community and having a recurrence of an old ailment far from their family physician.

So popular has Dr Headland's idea become that other local hospitals are finding it necessary to install the services as have several hospital and large laboratories in New York City.

Dr J J GOLUB, DIRECTOR OF THE Hospital for Joint Diseases in New York City, has coined a word to describe the profession of those engaged in the higher branches of hospital work. It is "hospitology." He says in an exhaustive and scholarly article in *Hospitals* that hospitology is derived from the Latin 'hospitium,' which means the place where a guest is received. It is defined as the art and science of (a) hospital service, (b) hospital administration, and (c) the special architectural and engineering features involved in hospital planning, construction, and equipment. He adds that

"Hospitology is concerned with those special features of hospital planning, construction, and equipment that give to the hospital completeness, unity, accessibility, flexibility, facility, and economy of operation. It recommends that consideration be given to community needs, sanitary and building codes, and the most desirable sites for hospitals. It suggests ways of properly grouping, orienting and planning hospital buildings and patients' wards and rooms, professional, technical and domestic services, nurses' residences, departments, and teaching and research facilities.

"All of the internal elements which make up a hospital and all of the external elements which affect the hospital are the concern of hospitology. The practitioners of hospitology are hospitologists."

At the Helm

THESE HOSPITAL OFFICIALS HAVE BEEN ELECTED

Frank Gulden, to be president of the Southside Hospital at Bay Shore

F Langdon Corwin, to be president of the directors of the Eastern Long Island Hospital at Greenport.

Charles H Lang, to be president of the board of managers of Ellis Hospital at Schenectady.

Prof E E Dwyer, to be president of the Mahopac Emergency Hospital.

Miss Edith M Lacy, to be superintendent of the Hudson City Hospital School of Nursing.

Mrs George H Miller, to be president of the Arnold Gregory Memorial Hospital auxiliary at Albion.

Milo Cleveland, to be president of the Brockport Hospital Association.

Mrs Rose Groening, to be president of the board of the united auxiliaries of the Mary Immaculate Hospital.

Dr Robert D Manning to be president of the Peekskill Hospital medical board.

DR IRVINE H PAGE, associate member of the Hospital of the Rockefeller Institute, has become director of clinical research at the Indianapolis City Hospital.

DR WILLIAM J TIFFANY, superintendent of the Pilgram State Hospital at Brentwood, and former member of the staff of Matteawan State Hospital in Beacon has been appointed state commissioner of mental hygiene to succeed Dr Frederick W Parsons resigned.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Responsibility of Surgeon for Acts of Nurse

Various attempts are made from time to time to fasten responsibility upon a physician for the acts of nurses, interns or other assistants who participate in the care of a surgeon's patient at a hospital. One such case, which resulted favorably to the doctor, was determined a few months ago in the Federal Courts*.

The case was one brought on behalf of an infant against the surgeon who had attended at his birth, the claim being that the doctor's negligence was the cause of injuries to the eyes of the plaintiff. The complaint was founded upon three separate claims of negligence. The first was that following birth the defendant had failed to give the child any personal attention whatsoever. The second charge was that defendant left the child in the care of assistants and servants who negligently inflicted injuries. The last claim was that after the negligence of the so-called agents, the defendant had failed to properly follow up the care of the infant.

There was upon the trial, it seems, little actual dispute as to what took place. The facts as developed will be summarized at some length.

The defendant was retained to care for Mrs. B., the infant's mother, during her period of pregnancy and to deliver her and render customary postnatal care. In due course Mrs. B. was admitted as a patient at a hospital of her own choice to give birth to her child. The defendant attended her and after efforts to bring about a normal birth, he elected to perform a Cesarean operation. Upon removal of the child the doctor patted him on the back and attended to the cord. The child cried, and appearing to be normal, it was handed by the doctor to the nurses, who swabbed the mouth and nose of the baby and took it from the operating room. The doctor then proceeded to devote his undivided attention to the mother, since there was profuse bleeding and the placenta had not yet been removed. The completion of the operation was satisfactorily brought about, following which the doctor washed and dressed, then went

to the mother's room to examine her before he devoted any of his attention to the infant.

It seems that the infant plaintiff was taken from the operating room by the nurse and carried immediately to the nursery on a lower floor in the hospital. Dr. H., when he first saw the child in the nursery after leaving the mother, found the child sleeping. He made an examination including an inspection of the cord and taking the pulse. He thereupon left the building.

A short time later, without the knowledge of Dr. H., one of the hospital nurses, a Miss M., undertook to administer to the child the so-called Crede treatment. She had available only a single tube of silver nitrate solution for the purpose which had been supplied by the Board of Health. Miss M. inadvertently wasted the contents of the tube, and had to obtain the solution for application to the infant from another source. She then requested another nurse to get her a quantity of two per cent silver nitrate solution from the drug department. A bottle of what purported to be such substance was supplied her, and Miss M. administered the treatment to the baby's eyes. An instant reaction was seen causing the eyes to turn white. She then applied some four ounces of a saline solution to the eyes. The result was that the eyes and eyelids were severely burned.

Later on that day, Dr. H. being told of the incident, ordered boric acid irrigations and other forms of treatment. The eyelids became inflamed and swollen and so remained for a long time. An eye specialist was brought in the second day after birth and he approved Dr. H.'s method of treating the child.

During the time that followed before the case came to trial various specialists were consulted. The child was for some time blind, but later improved greatly, so that at the age of three when the trial took place, he had regained substantial vision.

It was shown upon the trial that the custom was for the nurses to administer the Crede treatment as a matter of routine in all cases of normal delivery. It also was shown that in cases of Cesarean birth, although it was not bad practice to administer it, the Crede treatment was unnecessary.

* Harlow v. Bryant, 87 Fed. (2nd) 170

The evidence was that Dr H had given no orders that the treatment should be or should not be administered.

The hospital where the acts in question took place was established to be a charitable institution. The nurses who had participated in the matter were all employed by the hospital and paid by the hospital. The defendant's connection with the institution was as a member of its medical staff.

Upon such evidence upon the trial the case was submitted to the jury and a substantial verdict was awarded the infant plaintiff. The defendant thereupon took an appeal to the United States Circuit Court of Appeals, and succeeded in reversing the judgment.

The Appellate Court upon reviewing the case found that there was no possible basis upon the evidence for a recovery against the doctor on the first or third theories but that the plaintiff's case, if any, must necessarily rest upon the second theory, namely, that defendant was responsible for the negligent acts of the nurses. In holding that under the evidence the defendant was not responsible for what the nurses had done, the Court said, in the course of its opinion:

It cannot be said, therefore, that there was any duty or obligation on the part of the defendant to administer the treatment in the present case. He apparently had no intention of administering such treatment or of directing that it be done, as he gave no orders whatsoever at the time of birth to have it done, and after seeing the baby in the nursery a short time following the birth, he evidently deemed such treatment unnecessary as he left the hospital without giving directions that it be administered. The instillation was brought about by the nurse in charge of the obstetrical department of the hospital upon her own initiative and presumably in the performance of what she deemed to be her duty as an employee of the hospital. The treatment was administered out of the presence of the doctor, and after he had left the hospital, and he cannot be charged with the duty of foreseeing that the same would be undertaken without directions from him. We cannot accept as sound appellee's suggestion in his supplemental brief that the doctor, if he deemed the instillation unnecessary, should have instructed the nurses that it be omitted.

True he gave no orders that the treatment be not administered, but neither did he caution the nurse not to fall down and drop the baby and neither did he give orders that upon reaching the nursery they do not give the baby a cold shower. No inferences are to be had against the doctor under the circumstances here present for his failure to give any negative orders, and under the law existing at the time in question and under the facts present, there was no obligation on his part to administer the treatment, in fact, the assumption that he had formed a judgment to the contrary is justified. Such judgment is shown to have been in accordance with good medical practice. How can he, therefore, be held for the negligent act of another assuming to act, not under his directions, but acting in pursuance of an independent judgment—indeed a judgment contrary to his own? In the absence of a duty to act we think it cannot be said that he is responsible for another who acts without his authority with a resultant injury.

It might properly be said that the nurses assisting in the operating room at the time of delivery were the agents and servants of the doctor, for they were under his direct control and supervision and subject to his orders (although a contrary doctrine was held in the case of *Olander v Johnson* 258 Ill App 89), but to say that such relation continued in all postnatal treatment administered by them or by the hospital would cast too great a burden upon the surgeon. Even though there may be basis for the assertion that the relation of master and servant continued to the extent that they might undertake the performance of orders and directions of the doctor, yet the undertaking of a treatment not expressly or, as we think, impliedly, authorized, was beyond the scope of their authority as his agents.

A servant cannot create the relationship (of master and servant) by merely assuming to act. So far as appellant was concerned, the nurses in undertaking the instillation here made were mere volunteers. They cannot by their acts impose a duty upon the surgeon, not otherwise existing.

In assuming the care of the mother and child, the defendant impliedly contracted that he possessed and would use in the treatment of his patients a reasonable degree of skill and learning, and he thus owed a duty toward each to exercise such reasonable care and skill as a reasonably prudent and careful physician and surgeon would use under like circumstances. This was his burden and so far as the record discloses he fully and skillfully met it.

OUR OLD FRIEND, PAIN

Pain was cast in the role of a "blessing to humanity" by Dr Henry J Dowd, Buffalo nerve specialist, the other day.

"Hundreds of thousands of individuals now living would be dead had it not been for pain," Dr Dowd told members of the Gross Club, an association of medical men. "For," he explained, "it is pain which di-

rects the physician to the underlying source of disease.

"It must be remembered that a baby cannot speak before it is a year or so old. Its word for hunger is a cry or a yell. The same may be said for nerve cells, they cannot speak. Their word for irritation or undernutrition is pain."

Across the Desk

Shouting the Battle-Cry of Freedom

AMERICA IS THE LAND OF THE FREE, and the home of the brave. It is growing freer and freer, and braver and braver, all the time. If we may reword the redoubtable Dr. Coue, "everything, in every way, is growing freer, day by day." The new gospel of our age is that our organized minorities can have anything they want by demanding it and fighting for it. That is where the bravery comes in, or "nerve," as it is sometimes called. The subtle idea back of the socialized medicine drive is that medical treatment will be free.

If this seems incredible, scan the resolution passed by the Brotherhood of Painters, Decorators, and Paperhangers of America, at their convention in Buffalo last month, as quoted in the *Bulletin* of our Erie County society. It reads:

Resolved, That our Brotherhood and its delegates, assembled at Buffalo, N. Y., in September, 1937, recommend that our Federal Government, as well as all our States, provide for some form of socialized medicine, whereby our Brothers, as well as their families, will be protected in all cases of sickness, operations and hospitalization, free of charge, and be it further

Resolved, That our elected delegates to the American Federation of Labor Convention, to be held in Denver, Colo., in October, 1937, be instructed to introduce this resolution and fight for the adoption of same.

How About Free Wallpaper?

Not only ordinary medical care, but operations and hospitalization, are to be "free of charge." Yet what a laugh the assembled painters and paperhangers would have at some convention of doctors demanded free paint and wallpaper. True, wallpaper and paint do not have the sentimental appeal of medical care, but food, clothing and shelter are just as necessary to life and health as medicine, if not more so—why don't the decorators demand them gratis, too? The simple reason is that the professional propagandists who are advocating state medicine believe they can put the medical idea over and get lucrative jobs in running the machinery, but know that a drive for free hats, shoes, eggs and sausage would have no more

chance than a snowball in Satan's celebrated thermal resort.

Something Like a Black Eye

The pet argument of the socializers, that we ought to have health insurance because the British have it, received something very much like a black eye when Sir Henry B. Brackenbury, Chairman of the Council of the British Medical Association was over here last summer, en route to New Zealand, where he has been asked to act in an advisory capacity to the medical profession there. While in California, as guest at a dinner given by Dr. Clarence G. Toland, President of the California Medical Association, he was asked to tell how health insurance works in Great Britain.

It appears from Sir Henry's reply that some 18,000 of Britain's 50,000 practitioners are panel physicians, caring for about 18,000,000 citizens under employment. The yearly sum paid by the public authorities for each workingman is 13 shillings (\$3.25) of which \$2.25 goes to the physician to cover all costs of care, thirty-five cents goes to the pharmacist, and sixty-five cents is set aside for mileage and special expenses. Sir Henry had much to do, for the medical profession, with fixing the rates and rules, and says that the arrangement, on the whole, is satisfactory to both doctors and public.

But when asked how he thought such a system would work in this country, he proceeded to point out a few pertinent facts. The British doctors and patients are all of the same racial character and background, located in a small island. This is in contrast, he said, as reported in *California and Western Medicine*, for instance, to California, with its separate licensing boards for doctors of medicine, doctors of osteopathy and doctors of chiropractic and widely varying educational and other standards, or to the United States, where each of the forty-eight states, as an expression of police power in safeguarding the health and lives of its people, could set up systems of healing art licensure as diverse as exist today in some of the individual commonwealths. To be

noted also, in passing, is the fact that in the United States a national standard of licensure would be unconstitutional, because it would infringe upon those police powers guaranteed by the Constitution of the United States

The Peril of Party Politics

More important still, he noted, is the existence in Britain of the permanent civil service personnel, which has continuous and real authority to carry out the act and laws of Parliament, no matter what political group may name the nominal heads of the governmental departments

Without such expert, impartial and non-political supervision, he was of the opinion that a health insurance system such as exists in England Scotland, and Wales would in the United States from the beginning, be enormously handicapped in its organization, and prove practically impossible

of successful development. The distinguished speaker emphasized also, as his personal opinion, that it was doubtful, therefore, whether a successful health insurance system could be created here under conditions wherein political forces would be in major authority

Here, then, is a physician of the highest standing, in closest sympathy with the health insurance principle, visiting the only state in the Union where the state medical society has ever favored that plan, and he takes that occasion to declare that the very system he helped to frame would never work here. Could we have anything more conclusive?

Moreover, like the skilled diagnostician he is, he puts his finger unerringly on the sore spot—any such scheme would inevitably become the football of party politics here with disastrous results to physician and patient alike

Medical Editors and Homicidal Contributors

ANOTHER FEARSOME POSSIBILITY that has so far escaped mention in connection with state medicine is that the medical journals might have to print only the articles written by doctors who "stood in" with the "powers that be." Imagine the day when some smart young M. D. with political affiliations might stalk into the office, plank his article on boils on the editor's desk, and say, "Hey, you, the big boss says to print

this in the next number or you get the sack!" Such a picture, however, instead of being regrettable may seem highly desirable to some who have had their best efforts returned, with or without thanks. Perhaps they would sympathize with a character in J. M. Barrie's "My Lady Nicotine." He was a magazine writer who had had more than one MMS returned by unfeeling editors, and was in a homicidal mood.

As Barrie relates, he dreamed that he was witness in a murder trial. A magazine editor had been found dead on his office floor and one of his contributors was being tried for the murder. The dreamer on the witness stand told how he came up to the dead editor's office with an article for sale. He opened the door and saw the editor on the floor and the defendant kneeling on his chest and hammering at his head with the poker.

Q "What did you do then?" A "I said 'Oh excuse me,' and walked out, shutting the door behind me."

Without intimating at all that there is the slightest connection, your scribe takes the liberty of appending a little drawing that was the plate card of the Secretary of the State Society at the annual dinner at the recent convention in Rochester

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

Diseases of the Newborn By Abraham Tow, M.D. Octavo of 477 pages, illustrated New York, Oxford University Press, 1937 Cloth, \$6.50

This book is rather encyclopedic. If one is looking for direct advice on an individual case, he can find it, but more than that, it goes into the philosophy of etiology and conditions and is interesting to the student.

The bibliography at the end of each chapter is extensive, one chapter alone having 110 references.

It is recommended for those who are interested in covering the subject well.

WALTER D. LUDLUM

Clinical Laboratory Diagnosis By Samuel A. Levinson, M.D. and Robert P. MacFate, Ch.E. Octavo of 877 pages, illustrated Philadelphia, Lea & Febiger, 1937 Cloth, \$9.50

This book covers the subject for student, physician and technician, and has special chapters on such subjects as laboratory procedures in pediatrics and legal medicine which often are not emphasized. The book has been compiled from an outline which has been distributed for several years to the students in clinical pathology at the University of Illinois, College of Medicine. Sometimes a brief review of anatomy, physiology, biochemistry, or other previous study is added to aid the student in correlating the normal and abnormal findings.

There is a section on bacteriology, one on skin tests and other biological examinations, and one on histological technique. It is a large book containing a wealth of information, some of which will not be found so conveniently elsewhere. It deserves recognition as a standard work on the subject.

WILLIAM E. MCCOLLUM

Experimental and Clinical Studies of the Spine of the Dog By Geoffrey B. Brook, D.Sc. Octavo of 122 pages, illustrated Baltimore, William Wood & Company, 1936 Cloth, \$2.00

This monograph represents work of the author carried out under the fellowship of the Royal Veterinary College in Edinburgh. It is a decidedly thorough study on anatomy, physiology and pathology of the spine. The

author discusses the characteristics, hydrodynamics and circulation of the cerebral spinal fluid in a precise fashion. Especially commendable is his contribution on the use of ascending and descending lipiodol as applied to the spine of the dog. He appropriately deals with general and local effects following the subarachnoid injection of lipiodol.

The neurological surgeon reading this monograph is at all points impressed with the parallel characteristics of the spine of the dog and that of the human. The bibliography is well chosen, and serves as a satisfactory basis of discussion for veterinary and clinical purposes. The work represents a genuine addition to physiological literature.

RUSSELL MEYERS

Cancer and Diet. With Facts and Observations on Related Subjects By Frederick L. Hoffman, LL.D. Octavo of 767 pages Baltimore, The Williams & Wilkins Company, 1937 Cloth, \$5.00

There has been so much research upon the subject of cancer that it seems impossible to approach it from any angle that has not already been thoroughly investigated. In this volume the author reviews the various dietary theories of cancer from the time of Hippocrates to the present. The modern diet is discussed together with the metabolism of cancerous patients. Suggestions are made concerning certain foods, and diets are indicated. The author concludes that "over-nutrition is common in cancer patients to a remarkable and exceptional degree, and that overabundant food consumption unquestionably is the underlying cause of the root condition of cancer in modern life." In view of the fact that the present Cancer Commission has announced that diet and the cancer problem are not related, this presentation is most interesting. A careful study of this ably presented view point will repay the time given.

HENRY M. MOSES

Charterhouse Rheumatism Clinic Original Papers Volume 1. Quarto of 203 pages, illustrated New York, Oxford University Press, 1937 Cloth, \$5.25

This is the first volume of a new publica-

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

tion, one feature of which is the presentation of research work *in extenso*. There are three papers: Pathogen Culture and its Bearing on the Classification of Chronic Rheumatic Disease, by H. Warren Crowe, is divided into two parts, covering bacteriology and technique of selective culture of organisms supposed to be in etiologic relation to rheumatism. The Differential Sedimentation Test, by Harry Coke, is a highly technical investigation of the sedimentation of colloids in its bearing on infection. Spondylitis Adolescents with Associated Changes in the Sacro-Iliac Joints, by S. Gilbert Scott, is an exhaustive study of 200 cases of spondylitis in young adults, with associated pathological changes in the sacro-iliac joints. This first volume represents an enormous amount of highly specialized work, much of which is beyond the average practitioner, but all of which should be available to those making an intensive study of rheumatism. Illustrations are profuse, and bibliography is abundant. If the succeeding issues measure up to the present one, we may look forward to something unique in the history of medical research and writing.

J. M. VAN COTT

Memoranda of Toxicology. By Max Trumper, B.S. Third edition. 16mo of 304 pages. Philadelphia, P. Blakiston's Son & Co., 1937. Cloth, \$2.00.

This is a compact treatise of the diagnosis, mode of action and treatment of poisoning. The various poisons are classified, mostly, corrosives, irritants, and those acting on the nervous system. Methods of their detection are given. In this edition newer sources of poisoning and recent advances in toxicology are discussed. There is also a chapter on first aid and newly developed views on antidotes and methods of treatment.

EDWARD H. NIDISH

The Psychology of Eating. By Lewis R. Wolberg, M.D. Octavo of 321 pages. New York, Robert M. McBride & Company, 1936. Cloth, \$3.00.

The title of this book hardly discloses the nature of its contents. The reviewer was pleasantly surprised by its most interesting subject matter. Dr. Wolberg has succeeded in gathering from many sources a material from which he was able to write a fascinating history of the dietary habits of man. There are interesting references to the origin of cookery, descriptions of gluttons and gourmets, and some unusual notes about cannibalism. He goes on to discuss the physiology of metabolism in a manner that makes an interesting story. It is profusely

illustrated with many engaging anecdotes. The scientific aspect of the entire book is accurate, and is highly recommended as readable and instructive on the subject of diet. The physician could wisely recommend this book to those of his patients whom he plans to reduce.

WILLIAM S. COLLENS

High Blood Pressure. By I. Harris, M.D. Octavo of 132 pages, illustrated. New York, Oxford University Press, 1937. Cloth, \$3.75.

High Blood Pressure is a little volume detailing the results obtained in an experiment planned carefully and carried out logically upon a selected group of "human guinea pigs." A number of important observations are made regarding the care and treatment of hypertension cases.

The osmotic pressure in the blood is maintained at a constant level. Disturbances in osmotic pressure raises the arterial pressure. The kidney becomes affected early in hypertension. The elimination of nitrogenous end products is delayed, the impaired renal function showing itself only after gross structural changes have taken place. Malignant hypertension, with its resultant uremia, is an end stage of the ordinary hypertensive case. Polyuria is a constant sign of early hypertension. Nycturia is a sign of advanced hypertension. High protein intake increases the arterial tension. To replace the wear and tear of the tissues, a low protein intake with fats and carbohydrates in sufficient quantities to provide the calories for fuel is required.

The book is a valuable contribution to the problem of high blood pressure.

SIMON FRUCHT

The Avitaminoses. The Chemical, Clinical and Pathological Aspects of the Vitamin Deficiency Diseases. By Walter H. Eddy, Ph.D. and Gilbert Dalldorf, M.D. Octavo of 338 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1937. Cloth, \$4.50.

This is an excellent presentation of the clinical aspects of the vitamins in relation to human dietary. It brings up to date the conclusions of important studies in this field, particularly the clinical manifestations of vitamin deficiencies.

The profession in clinical work has not paid sufficient attention to, or perhaps does not know of, the factors in diseases, such as rheumatic fever, the anemias, diabetes, arthritis, and many states of "poor health" that are directly the result of lack of proper diet prescription to include adequate, much less optimum vitamin content.

This work would have wider distribution

among the profession, as the author's clinical conclusions should have, if the text were constructed as a monograph, the experimental discussions in an appendix or in an additional monograph

PAUL C. ESCHWELER

Hay Fever With Special Reference to Treatment by Intranasal Ionization By Olive Shields, B.M. Octavo of 57 pages, illustrated. New York, Oxford University Press 1937. Cloth, \$2.50

This book of fifty-seven pages gives a brief account of the anatomy, physiology and pharmacology of the vasomotor mechanism of the nose, and deals largely with the author's technic of intranasal zinc ionization in the treatment of hay fever. The author, achieving excellent results in seventy-two patients treated in 1936, emphasizes the fact that his technic of small current for a short time period produces no sloughing. He proposes, as an explanation of the effect of ionization, the hypothesis that it corrects the local ionic imbalance which he believes is the basic etiology of allergic conditions.

His results are more fortunate than those obtained by many workers in this country who have observed their patients over a longer period of time.

MATTHEW WATZER

Medical Urology By Irvin S. Koll, M.D. Octavo of 431 pages, illustrated. St. Louis The C. V. Mosby Company, 1937. Cloth \$5.00

Although this book comprises only about four hundred and twenty-five pages, it is quite comprehensive, covering the field of non-surgical urology in a thorough, painstaking manner. The book is well illustrated throughout. Dr. Koll has followed the newer and more popular method of listing references at the end of each chapter. He deserves credit for his useful contribution, and for the time and effort involved in its preparation. Practitioners and students should find it a useful and helpful guide having some advantages over the usual larger textbooks of urology. Perhaps its greatest usefulness will be to general practitioners located where urological advice and consultation are not always readily available.

AUGUSTUS HARRIS

Senile Cataract Methods of Operating By W. A. Fisher, M.D. Third revised edition. Duodecimo of 150 pages, illustrated. Chicago, H. G. Adair Printing Co., 1937. Cloth, \$2.00

This is the third edition of a book which originally was chiefly devoted to the intra-

capsular operation for cataract according to the method of Col. Smith. The book is now much broader in its purpose, and all methods of cataract extraction are discussed. The first chapter of 8 pages is by Ernst Fuchs and is worth the "price of admission." How so much wisdom could be packed in such a small space cannot be explained except by saying that it is typical of all the publications by that exceptional teacher.

The extraction by the method of Barraquer is explained by the originator while Dr. Holland of India explains the Smith technique. Dr. Wright of Columbus describes the regular method of extraction as it has been used for such a long time. The intracapsular methods of Knapp and Elschnig are briefly given and Dr. Fisher details the Homer Smith method of operating immature lenses. The author was one of the first to use the Smith technique and introduced his lid hooks that made this operation satisfactory and much safer.

In chapter VI the author gives advice from his extensive practical experience with the intracapsular methods and supplies many details of preparation of the patient and operating room as well as selection of instruments and training of assistants that apply to all forms of eye surgery. In such a small book the details must be limited but the plan of giving the technique by its originator is most praiseworthy. It is an excellent idea to collect the different operative procedures in one book so that beginners in ophthalmology can review the details of various methods.

RALPH I. LLOYD

Sexual Power By Chester T. Stone, M.D. Duodecimo of 172 pages, illustrated. New York, D. Appleton-Century Company, Inc. 1937. Cloth \$1.50

The reviewer is not in sympathy with the publication of this type of sex book for the laity.

We believe that possibly more harm than good may result, especially in sensitive neurotic individuals. Persons of average intelligence, with difficulties of sex function, would naturally consult their physician for confidential advice and proper guidance.

While it is advisable to bring the subject of venereal diseases into the light of day, it may prove disastrous psychologically to dwell upon the functional aspects of sex. This author, however, has manifested his sincere efforts in the preparation of the book. How much the average lay reader will gain is open to question.

THE USES OF PROTAMINE ZINC INSULIN

WALTER R CAMPBELL, M D, F R C P (C), F R S C, *Toronto*
Associate in Medicine, University of Toronto

*From the Department of Medicine, University of Toronto, and the Medical Service,
Toronto General Hospital*

The introduction in 1922 of the pancreatic hormone—insulin—has produced a great improvement in the condition of our diabetic patients. The earliest relatively crude extracts of pancreas, which often gave rise to irritation and even to sterile abscess formation, produced a prolonged effect on the blood sugar of man and animals, abolished ketosis, and permitted the use of more adequate diets for diabetics. More adequate control of infections and coma likewise followed. The use of these products, however, frequently sensitized the patients to the accompanying proteins or, due to their content of inorganic salts, caused an intense burning sensation, and methods of purifying them were therefore devised. With increasing purity of the product, however, the duration of action of the insulin was shortened, and at the same time its activity became more intense. For those patients capable of providing sufficient insulin for their own endogenous metabolism, but not sufficient to cope with the intake of carbohydrates following meals, a reasonable balance could be secured by using the unmodified insulin in two daily doses. It was found, however, that a steadily increasing number of patients required a greater number of injections per day, and hypoglycemic reactions became more numerous. The patients oscillated between hyperglycemia and hypoglycemia. The greater their

pancreatic insufficiency or the higher the level of carbohydrate in the diet relative to their natural tolerance, the more difficult it became to maintain such patients within normal limits. Indeed in many instances, through lack of understanding of the mechanisms involved, such unstable patients were placed in an insulin-sensitive or insulin-resistant class, and adequate treatment abandoned.

With the limitations of unmodified insulin in mind, numerous attempts to prolong the action of insulin have been made. Relatively little success attended these efforts until recently, when the investigations of two different laboratories produced improvements which, when combined, gave us the protamine zinc insulin now obtainable commercially.

Hagedorn and his associates have shown that the protamines, long known to cause precipitation when mixed with other higher proteins, would give precipitates with insulin. These precipitates varied in their degree of insolubility with the particular protamine, and with the hydrogen ion concentration to which they were exposed. A combination of the protamine obtained from *Salmo iridius* with insulin proved to be fairly highly insoluble at the hydrogen ion concentration of the body. A suspension of this precipitate of protamine and insulin injected under the skin is but slowly dissolved, thus slowly releasing the insulin to carry out its usual

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester May 25 1937*

function in the body. Hagedorn and his collaborators were able to show that the period of effectiveness of the insulin in diabetic treatment lasted two to three times as long as ordinary or unmodified insulin. Combinations of insulin with some other protamines were less effective however. Confirmation of these facts in animals and man, with protamine kindly furnished by Professor Hagedorn, was soon supplied by Joslin's associates, the group working in Toronto, and by others. It appeared that iroidus protamine insulin could be relied upon for effectiveness for some sixteen hours, and would therefore reduce the number of injections required by the patient to not more than two per day. Sometimes only one injection per day was required.

The most useful method of employing this compound was found by Hagedorn to consist in administering to diabetic patients on a controlled diet a dose of the quick-acting unmodified insulin in the morning, and a dose of the compound insulin in the evening. The advantages of this preparation besides the reduction in the number of doses required by severe diabetics, were reduction in the number of reactions encountered, a better control of ketosis, and a much more even course of the blood sugar throughout the day.

Replenishment of our supply of protamines was undertaken by Scott and Fisher working under Professor Best's direction in the Connaught Laboratories. A suitable protamine was produced from the spring or king salmon, *Oncorhynchus Tschawytscha* of the West Coast. The considerable advantage of being able to treat patients with a single dose of insulin rather than with two doses, early led us to attempt variations on Hagedorn's method. In *Oncorhynchus* protamine insulin we found a preparation which was highly effective for about twenty-two hours in man, and a residual effect lasting somewhat longer. Kerr, working in Best's laboratory, was able to confirm this in animals. Treatment with the single large dose was effective in a considerable proportion of our cases, and we were confirmed in this view by Joslin's and Wilder's groups, working independently. It was apparent, however, that the overlapping of the single doses was hardly

great enough in some instances, and the desirability of further prolongation of action was manifest. The attack on this problem then shifted to new ground.

Crystallization of insulin, it will be remembered, was accomplished by Abel in 1926. Many difficulties surrounded the successful repetition of this experiment until it was shown by Scott of the Connaught Laboratories, University of Toronto, that crystallization of insulin takes place only in the presence of certain inorganic salts, notably zinc, which is also present in the pancreas. Indeed Scott has shown that zinc is a constituent of the insulin crystal. Scott and Fisher were also able to show that insulin to which minute quantities of zinc were added produced a longer effect on the blood sugar in animals than insulin without this addition. We were able to duplicate this effect in patients with quantities of zinc far below those required to cause local injury, but the effect was much inferior to that of the protamine insulin compounds.

Rabinowitch and Wilder have had similar experiences. Scott and Fisher also showed that the effectiveness of the protamine insulin compound is materially reduced when it is uncontaminated by zinc, and, on the other hand, the addition of minute quantities of zinc to the mixtures of protamine and insulin produced a complex precipitate effective in their animals, and in those of Kerr, for much longer periods, besides conferring on it certain other valuable properties which make it possible now to dispense it in a single bottle prepared for immediate use. Other metals have a similar though less satisfactory effect. Clinically, in our hands, this addition has lengthened the effectiveness of insulin to more than thirty hours. In other words, today's breakfast, and even to some extent, tomorrow's breakfast, is metabolized under the influence of yesterday morning's dose of protamine zinc insulin, with some little effect from the injection immediately preceding the meal. In increasing degree, the carbohydrate load of lunch and dinner in excess of the natural insulin production of the patient is borne by the preceding dose of protamine zinc insulin. One can readily visualize how much more constant the blood sugar will remain

under these circumstances than when only unmodified insulin is used. The clinical advantages possessed by this modification of insulin have now been confirmed in several thousand cases of diabetes mellitus. Individualized treatment of diabetes is, however, no less necessary than heretofore, and one would not have you believe that the ultimate goal in diabetic treatment has been reached. Indeed, there still remain disadvantages in the treatment of patients

CHART I—CURVE 1 INDICATES EFFECT OF "PANCREATIC EXTRACT" IN LOWERING BLOOD SUGAR IN FIRST PATIENT TREATED. CURVE 2, EFFECT OF INJECTION OF EARLY INSULIN ON BLOOD SUGAR. CURVE 3 SHOWS FALL IN BLOOD SUGAR FOLLOWING INJECTION OF 20 UNITS OF A MORE PURIFIED INSULIN

with protamine zinc insulin, inherent in the properties of the substance, which will only be overcome by much further work. That many of these will be overcome in the near future is not to be doubted. In the meantime, however, it stands as a distinct advance in the treatment of the condition. I would also remind you that numerous compounds of insulin with dibasic amines, histones, tannin, iron, etc., are now known. Their properties are under investigation and it may be that, in the near future, treatment of diabetes will be better accomplished by a substance not at present in use.

Though it is probable that occasionally cures of diabetes do take place, in the main the condition must be regarded as a controllable, though incurable, disorder of metabolism. Adequate treatment must include rest to the injured organ, adequate food on which to grow, live, work, and play together with a restoration of the abnormal chemical state to a condition within physiological limits. Abolition of glycosuria, hyperglycemia, and ketosis must necessarily be accomplished if the patient is to receive maximum benefit from his treatment, not merely for the moment, but also for his future welfare. In recent years we have learned much about dietetic programs, but how far in any direction we may go with impunity is only slowly becoming apparent. It seems

CHART II

quite clear that where extremes are unnecessary they are also undesirable. It is also clear that early strict treatment and a continuous control of all cases of diabetes furnish the only satisfactory results. For a proportion of cases, readjustment of their dietetic regime will be adequate, for others, insulin to supplement that produced by the damaged pancreas may be required. Various means of determining which patients belong in which group have been recommended. I prefer, at the outset, to give to the patients a diet approximating their basal caloric requirement and subsequently raise it by successive increments to a maintenance level. Those whose natural tolerance or insulin production is adequate to furnish them with a maintenance diet do not need insulin, *per contra*, the others do.

What part shall the newer insulins play in the treatment of the diabetic? The answer lies in the properties peculiar to the different insulins. Unmodified insulin acts rapidly to restore serious metabolic derangements toward the normal, but unless carefully controlled, may easily expose the patient to the dangers of other metabolic derangements. Injected into the body it does not exactly imitate the normal secretion of insulin which becomes available in quantities adequate to meet the needs of the moment. Nor does protamine zinc insulin behave in a manner analogous to the normal insulin physiologically supplied. To meet some situations the ordinary insulin is too rapid, confronted with other situations the protamine insulin is too slow in its action. The endogenous metabolism of the individual is better supported by an insulin which is slowly released, as is the case with the combined insulins. A sudden influx of carbohydrate from the digestive tract is better disposed of by a rapidly acting insulin. For emergency purposes also, for quickly correcting the state of coma or precoma, for use during infections, for pre- and postoperative use, unmodified insulin is superior. We have, however, by the multiple dose method, been stretching the properties of unmodified insulin to cover the requirements of those diabetics most in need of support for their endogenous metabolism, and permitting those not so urgently requiring this support to carry through most of the twenty-four hours

without it. For both these latter types of cases protamine zinc insulin is the more valuable. In certain respects the protamine insulinate of Hagedorn was superior to the present protamine zinc insulin. But we have need of insulins with all the properties of both types separately, and also suitably combined together. Perhaps with a telescope to your mind's eye you can see such a combined insulin.

In the meantime there is an enormous psychological advantage in treating those patients who are producing too little insulin with a single dose in the early morning, thus leaving them free to plan their day without the further necessity of providing for additional insulin injections. This leads us to inquire whether we may reverse the procedure at present in use with unmodified insulin of treating the patient to counteract the peak loads produced by carbohydrate ingestion. May we, by using an insulin designed to control the endogenous metabolism of the individual, permit the pancreas to accumulate its own meager store of insulin for release during the period of the peak load after meals? Whether or not the explanation suggested holds good, there is adequate evidence that, by slightly overtreating the endogenous metabolism with compound insulin, a more successful maintenance of physiological conditions throughout the twenty-four hours may be accomplished. It would appear probable that most patients requiring insulin because of chronic insufficiency of their own insulin producing mechanism, fare better with the compound insulin than with the unmodified product. Some brief case reports will illustrate the type of results obtained. It is, of course, possible to begin the treatment with protamine zinc insulin by administering a small dose $\frac{1}{2}$ to $1\frac{1}{2}$ hours before breakfast and thereafter increase the dose until an adequate control is attained, and to many this plan will commend itself. In many instances, however, the time required will prove inordinately long since the development of maximum effect of the combined insulin is so slow. The same result may be attained more rapidly and an idea of the dose required may be obtained by making the patient sugar free with ordinary insulin and then transferring him to protamine zinc insulin later. Since a com-

parison between the effects of the two insulins was desired, the latter method has been adopted in the following cases

Charts I and II illustrate the difference in action of two insulins. The first chart* shows that the 1922 insulins had an effect on the blood sugar of diabetics lasting from twenty-four to twenty-seven hours, while in 1923 a purer insulin acted much more rapidly, the blood sugar reaching its low point in about four hours.

Chart II shows the effect of equal doses, twenty units, of present day unmodified insulin and protamine insulin on the same persons during fasting. With the unmodified insulin the maximum lowering of blood sugar is attained in one to two hours and the blood sugar lowering effect is over in three hours. With protamine insulin on the other hand the fall is less precipitous and may last for many hours. Larger doses in each case will tend to prolong the action, but this effect is more pronounced in the case of protamine insulin, while the probability of inducing overdosage symptoms is greater in the case of the unmodified insulin.

CASE 1 A fifty-eight year old male, admitted for hemorrhoidectomy, was found to have great thirst and loss of weight for the past year. Marked glycosuria and a fasting blood sugar of 0.166% were found, but his general physical condition was good. He was treated by diet and an increasing amount of insulin.

On a diet of P 50, F 197, C 54, he required twenty-five units of unmodified insulin twice daily to maintain normal blood sugars and freedom from glycosuria and ketosis. Curve 1 in Chart III shows a fairly successful control of the blood sugar with two sharp falls after the insulin was administered. Transferred to a single dose of thirty units of protamine zinc insulin the blood sugar was successfully controlled as shown by Curve 2. In each case a post-prandial rise in the blood sugar is seen following the noon meal, but this is within the normal limits.

He has remained free of glycosuria and ketosis on this program for the past ten months. Fasting blood sugars are normal. Saving of insulin, forty per cent.

CASE 2 A woman, aged seventy-two, had diabetes and pruritis vulvae. Eight years progressive diminution of vision, four years

Patient's weight, August 22, 150 lbs., August 29, 154 lbs., September 5, 150 lbs.

hypertension B P 175/100 Chronic degenerative myocarditis Cataracts Diabetes controlled on a diet of P 49, F 153, C 43, with thirty units of regular insulin twice daily

* The first curve is redrawn from one in *Can. Med. Assn. J.*, 12 141, 1922, and is here reproduced with their permission; the second and third curves are taken from the *Journal of Metabolic Research* 2 637, 1922

Curve 1 (Chart IV) shows the blood sugar remaining normal on this program through the twenty-four hours. One week after she was changed to forty units of protamine zinc insulin at 8 A.M. The blood sugar curve (curve 2) showed an unsatisfactory response after meals, but normal values were maintained after 8 P.M. On the tenth day on this program the morning fasting blood sugar fell to 0.059%, and the dose of insulin was reduced.

Curve 3 shows that on thirty-five units of compound insulin the blood sugar remains normal throughout the twenty-four hours.

CHART III—CASE 1

CHART IV—CASE 2

She has been successfully maintained on the same diet and insulin for the ensuing eight months. Saving of insulin, forty-five per cent. In this instance it seems apparent from curve 2 that an equilibrium had not been reached though the patient had been receiving protamine zinc insulin for a week prior to the test.

CASE 3 On admission a boy of fourteen years complained of polyuria and polydipsia for five months with weakness and numbness of both legs for the past month. Has lost considerable weight and feels sleepy and tired. Father and paternal grandmother, grandfather, and uncle have diabetes. General physical condition normal, except for loss of weight. Vessels soft. B.P. 118/70, reflexes normal. The numbness complained of was indefinite and uncertain. Blood sugar on admission 0.285%, glycosuria marked, no ketonuria. CO₂ C.P., 62 Vol %. On a diet of P 45, F 219, C 60, required twenty-five units of insulin twice daily to maintain normal blood sugars.

Curve 1 (Chart V) shows the effect on the blood sugar curve during the twenty-four hours. A slight rise took place after breakfast, followed by a rapid fall at noon, a rise following lunch, and a further fall commencing at the time of the second injection and slow rise during the night.

Curve 2 taken when but a single daily injection of twenty-five units of unmodified insulin was given indicates the need for the second injection, the blood sugar, though showing an initial fall, rose next morning to 0.160%.

He was then given thirty-five units of protamine zinc insulin and on account of low blood sugars (no symptoms of reaction occurred) this was reduced to twenty units. The urine remained sugar and ketone free throughout, curve 3 shows that he remained within the normal band throughout the twenty-four hours. Saving of insulin, sixty per cent.

CASE 4 Male, aged forty-five. Sugar found in urine ten years ago. Amputation right leg seven years ago (Buerger's disease?). Adhered rather loosely to a qualitatively restricted diet. Having struck his left foot with his cane two weeks before, he was admitted to this hospital with thrombosis of left popliteal and medial plantar arteries and impending gangrene. Treatment proved unavailing and Griggs-Stokes amputation was done. The stump healed well. He became aglycosuric on a diet approximating his basal caloric requirement composed of P 36, F 130, C 35, and remained so when 5 C and 20 F—200 calories—were added to this. When the diet was raised to P 44, F 150, C 50,—1726 calories

—intermittent glycosuria appeared and the fasting blood sugar was above normal. Transferred to a diet of P 44, F 110, C 140, isocaloric with the last, glycosuria and hyperglycemia became marked and insulin was required. As the glycosuria was of the postprandial type, not successfully removed by small doses of protamine zinc insulin, a combination of protamine zinc insulin and regular insulin was advised.

CHART V—CASE 3

Curve 1 (Chart VI) shows the results on the blood sugar of thirty-five units of protamine zinc insulin and ten of unmodified insulin at 8 P.M. The hyperglycemia following breakfast is not quite satisfactorily controlled though no glycosuria occurred. The remainder of the day shows a satisfactory control of the blood sugar. Placed on the approximate equivalent of these insulins—namely forty units of protamine zinc insulin only—for seven days, the second blood sugar curve was obtained. While controlling the blood sugar during the day reasonably well the dose is not so satisfactory since the blood sugar during the night is

continuously in the hypoglycemic zone. Correction of the latter by reduction in the number of units of protamine zinc insulin will not be satisfactory because postprandial glycosuria will result. The alternative procedure in such cases as object to using the two insulins is the reversion to a diet lower in carbohydrate.

CHART VI—CASE 4

CHART VII—CASE 5

CASE 5 Female, aged fifty-four, was admitted to Toronto General Hospital in February 1936, with adenocarcinoma of the body of the uterus. She was given very intensive high voltage x-ray and radium therapy with, thus far, very satisfactory results. Readmitted in July for re-examination, sugar was found in the urine, which, on previous occasions, had been sugar free. Questioning revealed the development of a

diabetic symptomatology in the interval and a blood sugar tolerance test was confirmatory. In May she had developed a paralysis of the right external rectus muscle. The patient became sugar free on a maintenance diet of P 46, F 169, C 43, by the aid of fifteen units of regular insulin twice daily. Curve 1 (Chart VII) shows the range of blood sugar throughout the twenty-four hours on this program.

Curve 2, obtained after a prolonged trial of a single dose of fifteen units of unmodified insulin daily, shows a failure of adequate control though the patient remained aglycosuric with moderately raised fasting blood sugar levels. The substitution of fifteen units of protamine zinc insulin for the regular type failed to show much improvement (See curve 3). It is not improbable that in this case a somewhat larger dose of protamine zinc insulin would have controlled the blood sugar adequately. That point will be determined on a later admission. The method adopted, however, was to use fifteen units of the combined insulin to control the endogenous metabolism with ten units of regular insulin to lower the postprandial blood sugar. Both doses were given before breakfast. Curve 4 demonstrated that satisfactory control was obtained. The saving of insulin in this case is comparatively small.

CASE 6 Female, aged seventy-three, was first admitted to Toronto General Hospital in 1924 with symptoms of diabetes dating back one year. Hypertension and chronic myocarditis and chronic glomerulonephritis were recognized at this time. She was rendered aglycosuric by diet alone but two years later required insulin. In 1930 her vision became impaired due to retinal changes. Two years ago hypertension increased and she noticed pain in the chest with dyspnea on exertion. The severity of this has been increasing. In April a more severe attack of pain lasting two hours with great shortness of breath was experienced. Nocturnal dyspnea then commenced. No edema of the feet. Readmitted in July 1936 with coronary thrombosis and acute pulmonary edema, she improved in an oxygen tent. On a diet of P 55, F 120, C 65, the diabetes was not adequately controlled by thirty units of regular insulin bid but greater success was attained by the use of twenty-eight units before breakfast and supper with twelve units of regular insulin at 11 P.M. The first curve shows however, that on this regime the blood sugar fell too low at night. Substitution of forty units of protamine zinc insulin proved a little more satisfactory in this respect but

failed to control the postprandial hyperglycemia as shown by curve 2 (Chart VIII).

From curve 3 it seems apparent that even fifty units of the slowly absorbed insulin was not available in sufficient amounts at meal time to deal adequately with the carbohydrate content of the meals. She was therefore given a combination of the two insulins—forty units of protamine zinc insulin and fifteen of the unmodified insulin proved adequate (See curve 4).

CASE 7 Male, aged seventy-five, diabetic four years, arteriosclerosis, gangrene right foot with Griggs-Stokes amputation. Diet was P 50, F 170, C 50. He was stabilized on twenty-five units of regular insulin twice daily and healing of the stump was well-advanced before this record commences.

CHART VIII—CASE 6

The dose of unmodified insulin was later reduced to twenty units bid. The first curve (Chart IX) indicates that an excess of insulin was being administered in the morning dose but the rapid rise in the blood sugar after 11 P.M. showed the need for a sustaining dose to assist in his endogenous metabolism.

Curve 2 taken on the fifth day after placing him on a single dose of twenty units perhaps indicates this more clearly. Though he remained aglycosuric during this time the morning fasting blood sugars likewise indicate the insufficiency of the single dose by a rapid rise to 0.200%.

He was transferred in the usual manner to thirty units of protamine zinc insulin in a single morning dose. As this dose lowered the fasting blood sugar to 0.051%, a change to twenty-five units was made, which proved to be adequate.

Curve 3 shows that his blood sugar rises slightly after the noon meal, but not more than that of a normal person and thereafter drops back to normal levels. We had an opportunity to observe him four months longer in the hospital, during which time his urine remained sugar free and the blood sugars normal. He was discharged to a home for the aged, having been satisfactorily controlled on twenty-two units of protamine zinc insulin for about three months. Saving of insulin, about fifty per cent.

Discussion

For the sake of clarity in the charts accompanying the case reports, the limits of the normal blood sugar levels, 80 to 120 mg per 100 cc of blood, have been emphasized. While temporary fluctuations of some considerable size due to excitement, pain, fear or other emotional causes may sometimes occur in the sugar content of normal blood, the most frequent variation from the normal band occurs following the meals during carbohydrate absorption. It may be entirely absent and seldom exceeds 140. Much less frequently, and usually following late after excessive carbohydrate ingestion, the blood sugar falls to hypoglycemic levels. The relative constancy of the normal twenty-four hour blood sugar curve may be used as one of the criteria for determining the effectiveness of a treatment in a case of diabetes mellitus. By this measuring stick, that is restoration of the diabetic to the normal physiological limits, it must be acknowledged

that many of our previous types of treatment fall more or less short of being satisfactory. Suitable application of protamine zinc insulin, with or without the use of unmodified insulin in addition now makes possible in all cases of diabetes the restoration of normal blood sugar levels throughout the twenty-four hours.

The twenty-four hour blood sugar curve establishes definitely whether or not the patient is being successfully controlled. It presents certain difficulties in the routine treatment of patients and is

CHART IX—CASE 7

no longer necessary for the majority of patients. It is reasonably certain in most cases that (1) if the patient is sugar free throughout the day, (2) has a low normal fasting blood sugar, (3) a blood sugar below 0.140% two and one-half hours after breakfast, and (4) no evidences of hypoglycemia in the late afternoon or evening, his blood sugar curve will fall within the usual limits. The question whether or not the diet prescribed is adequate is only to be answered by continued observation. It is, of course, no less important than with the unmodified insulin, that the patient should be adequately trained in dietetic measures, how to give insulin, the symptoms and dangers of hypoglycemia and how to cure it, elementary urinalysis, etc.

Modifications of the Single Dose Method

In a small group of cases it is obvious that many of the methods employed cannot be illustrated. With protamine zinc insulin it is not nearly so difficult to obtain normal fasting blood sugars as with unmodified insulin. In a sense this may

tion of the zinc modification permits an overlapping of the effects of two or more doses of insulin so that protamine zinc insulin controls hyperglycemia and glycosuria after breakfast decidedly more effectively than the earlier protamine insulin. It is, however, definitely inferior to unmodified insulin for this purpose. When necessary, a dose of both insulins may be given in the morning with good effect. This is particularly useful with the higher carbohydrate diets. Moving back the time of injection two or three hours before the expected meal in order that more insulin may be absorbed is of some value. It is not so effective as it was with the protamine insulin of Hagedorn, because the absorption rate is slower. Hagedorn's most commonly used procedure of administering a dose of regular insulin in the morning and a dose of protamine insulin in the evening is now seldom required. Because of the longer period of action of protamine zinc insulin, both insulins, if necessary, may now be administered in the morning. Likewise the use of a second overlapping dose of protamine zinc insulin given some hours after the first is now less frequently necessary, useful as it may prove on occasion. The use of additional meals late at night is a European habit of longstanding but one somewhat foreign to our custom.

Its introduction to cure or prevent an expected hypoglycemia during the night is a new and unnecessary complication in the routine of the diabetic's life which all will agree should be simplified as much as is practicable. It has been our experience that with a little more prolonged study of the individual patient and his reaction to diet and insulin combinations it is possible to avoid the introduction of this device. In a patient with low tolerance when the use of the two insulins before breakfast is to be avoided and the single dose of protamine zinc insulin is to be applied, possibly the most effective means of attaining success is, first, use a diet comparatively low in carbohydrate, next, give such a dose (about 1½ hours before breakfast) as will insure a low normal fasting blood sugar on the following day, then arrange the diet so that the least portion of the carbohydrate is in the breakfast and the

be regarded as equivalent to pushing the patients back into an earlier stage of diabetes since in the earlier or less severe phases only the ability to control postprandial hyperglycemia and glycosuria is lost. Too large a dose tends to produce an excessively low blood sugar during the night. The greater prolongation of ac-

The dose of unmodified insulin was later reduced to twenty units bid. The first curve (Chart IX) indicates that an excess of insulin was being administered in the morning dose but the rapid rise in the blood sugar after 11 P M showed the need for a sustaining dose to assist in his endogenous metabolism.

Curve 2 taken on the fifth day after placing him on a single dose of twenty units perhaps indicates this more clearly. Though he remained aglycosuric during this time the morning fasting blood sugars likewise indicate the insufficiency of the single dose by a rapid rise to 0.200%.

He was transferred in the usual manner to thirty units of protamine zinc insulin in a single morning dose. As this dose lowered the fasting blood sugar to 0.051%, a change to twenty-five units was made, which proved to be adequate.

Curve 3 shows that his blood sugar rises slightly after the noon meal, but not more than that of a normal person and thereafter drops back to normal levels. We had an opportunity to observe him four months longer in the hospital, during which time his urine remained sugar free and the blood sugars normal. He was discharged to a home for the aged, having been satisfactorily controlled on twenty-two units of protamine zinc insulin for about three months. Saving of insulin, about fifty per cent.

Discussion

For the sake of clarity in the charts accompanying the case reports, the limits of the normal blood sugar levels, 80 to 120 mg per 100 c c of blood, have been emphasized. While temporary fluctuations of some considerable size due to excitement, pain, fear or other emotional causes may sometimes occur in the sugar content of normal blood, the most frequent variation from the normal band occurs following the meals during carbohydrate absorption. It may be entirely absent and seldom exceeds 140. Much less frequently, and usually following late after excessive carbohydrate ingestion, the blood sugar falls to hypoglycemic levels. The relative constancy of the normal twenty-four hour blood sugar curve may be used as one of the criteria for determining the effectiveness of a treatment in a case of diabetes mellitus. By this measuring stick, that is restoration of the diabetic to the normal physiological limits, it must be acknowledged

that many of our previous types of treatment fall more or less short of being satisfactory. Suitable application of protamine zinc insulin, with or without the use of unmodified insulin in addition now makes possible in all cases of diabetes the restoration of normal blood sugar levels throughout the twenty-four hours.

The twenty-four hour blood sugar curve establishes definitely whether or not the patient is being successfully controlled. It presents certain difficulties in the routine treatment of patients and is

CHART IX—CASE 7

no longer necessary for the majority of patients. It is reasonably certain in most cases that (1) if the patient is sugar free throughout the day, (2) has a low normal fasting blood sugar, (3) a blood sugar below 0.140% two and one-half hours after breakfast, and (4) no evidences of hypoglycemia in the late afternoon or evening, his blood sugar curve will fall within the usual limits. The question whether or not the diet prescribed is adequate is only to be answered by continued observation. It is, of course, no less important than with the unmodified insulin, that the patient should be adequately trained in dietetic measures, how to give insulin, the symptoms and dangers of hypoglycemia and how to cure it, elementary urinalysis, etc.

Apart from infectious, acidosis arises from two sources—the use of too little insulin and an unsuitable ratio of body fuels. To detect acidosis is easy, it is much harder to remember to look for it and many times as hard to estimate justly its severity. Given sufficient time, protamine zinc insulin will of course control acidosis. Unless one is prepared to risk increase in severity and to neglect additional hours of discomfort, anxiety, and pain for the patient and his friends, it would seem advisable to use a more rapidly acting insulin.

Diabetic coma is an emergency and should be treated as such. Death from diabetic coma today comes most often from neglect to treat the patient early enough or vigorously enough, not from the metabolic disturbance itself, which can be abolished, but from circulatory failure caused by prolonged exposure to the metabolic disturbance. A slow-acting insulin is not absorbed sufficiently rapidly and does not begin to act before the patient should be well on the way to recovery if unmodified insulin were used in sufficient dosage. It is true that it will act if you can afford to wait, but this is a therapeutic *tour de force*. However, Wilder's suggestion that it be used as an adjuvant to regular insulin in such cases is a good means of smoothing out the irregularities in administration and action of the regular insulin. I must confess, though, that at present I pin more faith on early treatment with massive doses of regular insulin.

Though these situations can hardly be regarded as contraindications to the use of protamine zinc insulin, it would appear that it is less valuable than the unmodified product under these circumstances. Of true contraindications in diabetes mellitus there are none. In our first fifty cases we encountered no instances of generalized hypersensitiveness. Recently though, we have encountered two patients with rather severe local reactions which gradually subsided under continued treatment.

Hypoglycemia

Particular care should be taken to impress on patients that hypoglycemia is dangerous. It is true that in the stabilized patient, reactions are less frequent than

with unmodified insulin, but they may be severe and may return after temporary cure owing to the fact that insulin undissolved at the time of the initial symptoms is gradually released into the blood stream. Whether it is because the increased blood flow of exercise washes increased amounts of the hormone into the blood stream or not, is as yet unknown, but there appears to be a definite tendency for attacks to occur following, sometimes by several hours, unaccustomed exertion. For this reason it is desirable that the final suitable dose of protamine insulin should be fitted to the patient under conditions approximating his ordinary routine of living. The dose required at rest in a hospital is not that required on an ordinary business day. The liability to hypoglycemia increases as the day wears on, and sometimes occurs late at night. The business men's gym class and overindulgence in dancing have been responsible at times for unexpected reactions. Swimming races and other forms of strenuous sports should be avoided.

The blood sugar is normally maintained within a narrow band by a balance between the insulin release and adrenal release. This homeostasis is upset by an excess of unmodified insulin acting rapidly and the attempt at correction produces symptoms strikingly like those produced by a dose of adrenalin. Flushing or pallor, tremulousness, palpitation, tachycardia, pounding of the superficial arteries, sweating, loss of judgment, and anxiety or fear are symptoms common to both. They attract early attention and prompt relief is obtained by administration of a soluble, rapidly assimilable carbohydrate. It is known, however, that frequently hypoglycemic levels are attained without production of the usual early symptoms. These latter reactions more closely resemble those encountered when the compound insulins are being used. Rapidity of fall of the blood sugar, which excites the compensatory mechanism, is absent and the early symptoms of hypoglycemia are present only in mild form, if at all. Great fatigue, a desire to sleep, a fullness in the head, thick-wittedness, repetitiousness, contrariness, argumentativeness, loss of suavity or politeness, or even the exaggerated correction of these

greatest in the evening meal—and lastly, delay the evening meal

It should not be assumed that an accurate adjustment of a patient's dose of protamine insulin to one set of conditions will necessarily be suitable when those conditions are altered. While there is a considerable safe margin, gross changes in the proportions of rest and exercise or alteration in the time and composition of the various meals even though the total day's allowance of food remains the same, may cause either glycosuria or reaction. The margin of safety becomes smaller the higher the carbohydrate content of the diet or the harder the physical work performed, provided, of course, that these latter factors have not already been taken into consideration.

Economy of Insulin

The economical use of insulin is of some importance to the patient who must pay for it. The results vary with the carbohydrate level of the diet used, although this is apparently not the sole factor. Possibly total caloric intake may play a role, as with high carbohydrate undernutrition diets, this is less in evidence. With high carbohydrate high calory diets some economy may be demonstrated. With adequate maintenance diets, low in carbohydrate, an average saving of forty per cent of the former requirement of unmodified insulin is found. The change over from one to the other may be made on this basis always remembering to use sixty per cent (of the former requirement) of the unmodified insulin on the first day and thirty per cent on the second day along with the protamine zinc insulin to prevent a glycosuria appearing before the slow acting insulin has time to be absorbed. Subsequently when changes in the dose of protamine zinc insulin are required seldom is a change of less than five units productive of the desired result.

Infections, Acidosis, and Coma

It has been noted that protamine zinc insulin acts very slowly. This would seem to limit its usefulness to such conditions as do not require large amounts of insulin in the circulation at one time. It has been well-shown that during in-

fections the effectiveness of unmodified insulin is materially reduced. It is our impression that the general health of patients receiving protamine zinc insulin is materially improved and that infections are less frequent among them. It is very evident, however, that, once an infection has been acquired, the patient is much less effectively protected against acidosis than with unmodified insulin. Patients receiving the compound insulin should be warned to report to their physician on acquiring even slight infection. Because of its greater effectiveness, unmodified insulin in adequate dosage should be employed in those cases where the infection is severe. Similarly when an operation becomes necessary the rapid action of unmodified insulin contributes to its superior efficiency. Hypoglycemia is of course never encountered if the dose is suitably buffered by carbohydrate. The short duration of action of unmodified insulin tends to leave the night hours unprovided with the essentials for complete combustion of foods. Much of the carbohydrate has already been burned, the insulin effect is over, leaving a defective balance of the fuels, largely protein and fat, burning at this time. In consequence, ketonemia and ketosis may occur in the early morning hours. In the more severe cases of diabetes early morning nausea may be experienced unless provision is made for additional doses of insulin during the night. Mild acidosis may even result. The delay in the complete absorption of the protamine zinc insulin is effective in controlling such a ketosis, since not only is there insulin available during these hours, but a larger amount of carbohydrate may be placed in the evening meal for combustion during the night. For many patients a vague and indefinite awareness that they are not feeling quite well* is abolished by relief from "morning ketonemia."

* Wilder has recently suggested (*Annals Internal Medicine*, p. 13, July 1937) that the improvement in the sense of well being in patients taking protamine insulin is due to the prevention, by the combined insulin of intermittent periods of azoturia resultant on protein breakdown. This action he has beautifully demonstrated. There is as I read his article, no difference of opinion between us. He is there concerned more with the increased sense of strength and "fitness" over considerable periods of time, which undoubtedly results from the use of combined insulin, whereas the paragraph above is concerned with relief from a feeling of unwellness which gradually disappears during the day when carbohydrate and any type of insulin in sufficient quantities are supplied.

previous total dosage of unmodified insulin may be given in a single dose $\frac{1}{2}$ to $1\frac{1}{2}$ hours before breakfast. On the first day sixty per cent of the former allowance of unmodified insulin given in two equal doses, morning and evening, and thirty per cent given in a single dose on the second morning prevent a glycosuria which otherwise might take a week to clear. Still remembering its slow action, little reliance should be placed in blood sugar levels until a week of treatment with the new insulin has been completed. Glycosuria may likewise be an unsatisfactory guide at this time, although it may be said that glycosuria before breakfast or a fasting blood sugar of 0.140% indicates insufficient insulin or an unsatisfactory arrangement of the carbohydrate in the diet, postprandial glycosuria

coupled with hypoglycemia after midnight may have a similar meaning or may indicate the desirability of using a dose of regular insulin in the morning along with somewhat less protamine zinc insulin.

Freedom from glycosuria with hypoglycemia in the afternoon, evening or early morning hours indicates that excessive quantities of protamine zinc insulin are being used. But again, too hasty conclusions on these points are not advisable since they may rest on false premises. Insufficient observation of the patient and his reaction to diet and the insulins accounts for most of the unsatisfactory results in the treatment of diabetes with protamine zinc insulin.

MEDICAL ARTS BLDG

Discussion

DR. WILLIAM A. GROAT, *Syracuse*—In this matter of the improvement in the effects of regular insulin by combining it in some manner with a protamine, to have the value of the experience of the Toronto group following the original work of Hagedorn, is extremely valuable to all of us. While I realize that my experiences may be of little interest to you, they have been interesting to me and are the ones I know the most about.

Following the work of Hagedorn there was made available for clinical experimentation in this country nearly two years ago through the Eli Lilly Company a protamine insulin combination or mixture to be prepared extemporaneously. In starting out with something still in the experimental stage one must have a plan, a protocol, a basis on which to work. We postulated first that in order to be useful this new thing must be acceptable to patients, it must be within their comprehension and their ability to handle themselves, it must confer upon them distinct benefits. No matter how useful it might seem to be in the laboratory or in controlled experiments, unless it conferred the benefits upon the patient of reasonable ability and good training, it would not have much clinical value. We, therefore, started out with a group of ten patients selected on the basis of their training and experience as diabetics over a period of years with a demonstrated ability to show good results with such methods as were put at their disposal. We found that these were able to mix their own protamine insulin compound, the product at that time coming in two parts

—a protamine solution and an insulin solution—to preserve it properly, use it correctly and prolong the action and smooth the insulin effects. We rejected the plans of Hagedorn and others for giving two different kinds of insulin, either at different times of the day or at the same time of day, as not being practical and suitable for use by the average patient.

The next improvement was the combining of very small amounts of calcium or zinc with the protamine solution used for making the mixture extemporaneously. Our group of patients found a further prolongation and smoothing of the action of the protamine insulin mixture. We found little if any difference in our limited experience between the calcium and the zinc mixtures but in the consolidated experience it developed that the zinc mixture did work somewhat longer and smoother and, as Dr. Campbell has explained, there are good reasons why this should be so.

The next step was the ready mixed protamine zinc insulin and again our patients adapted themselves to it with considerable ease and found it more practical. Our results with this group continue good and with a still further experimental product it continues good although I question whether there is any particular advantage in this latest mixture, which Dr. Campbell has not referred to and which I will therefore say no more about.

The advantages to the patient are, speaking now of the protamine zinc insulin, a prolongation of the action for a period of over twenty-four hours, sometimes even

faults, in short, signs of waning cerebral control, are more frequently seen. Headache and slight nausea, even vomiting (prone to be attributed to "car sickness" if driving in a motor) are sometimes accompaniments. Convulsions or unconsciousness possibly terminating in death may result from prolonged lack of treatment. Patients receiving protamine insulin should carry glucose candies at all times, and should never attempt to "fight off" reactions. They should eat a candy each thirty minutes until some starchy food can be obtained. Bread and corn syrup or bread and honey are useful combinations for their immediate antidotal effect and for warding off a subsequent return of symptoms. When more seriously incapacitated an intravenous injection of glucose may be necessary.

More General Effects

The general health and the feeling of physical fitness of the patients has been improved by the use of protamine insulin in comparison with their condition on regular insulin. The more severe diabetics who tended to develop ketosis immediately previous to their next dose of insulin with a feeling of malaise or even of nausea, have remarked on their increased well-being. Infections are less frequently encountered. To the patient himself, apart from his increased sense of fitness and well-being, there is nothing of greater importance than the feeling of relief from numerous injections. It is not relief from the physical discomfort of the injections that pleases him so much as the sense of freedom from the continuous necessity for planning his life around a routine of meals and injections at specified times. "I get up in the morning, shave and take my insulin, then wander down to breakfast. That chore is done, and I feel free for the rest of the day," said one patient.

The progress of these patients after leaving hospital is of great interest. While it is true that an improvement of tolerance did take place in some of our patients receiving unmodified insulin, we have been glad to find that, as time passed, many of the patients taking protamine insulin required smaller and smaller doses, several patients whom we

could not maintain sugar free without a combination of both regular and protamine have gradually accommodated themselves in some unknown way and are now able to dispense with the unmodified insulin. Not all cases show this improvement however, and it has been impossible to predict with any certainty which patients will improve in this manner. It is usually a slow process extending over months, possibly over years. It will be of great interest in this connection to observe whether or not patients not absolutely requiring insulin gain tolerance by continued administration of small doses of protamine zinc insulin over a considerable period of time.

The fact that intense hunger is seldom a symptom of protamine insulin hypoglycemia does not augur well for its success in relieving obstinate anorexia. With regard to improving the nutritional state of emaciated patients it will be remembered that carbohydrate is burned by preference when sufficient insulin is available and that its protein sparing action was demonstrated in some of the earliest work on insulin. Combinations of unmodified insulin to induce hunger with protamine zinc insulin to "spare" protein throughout the twenty-four hours may possibly prove more effective than the use of unmodified insulin alone.

Application to Patients Now Receiving Unmodified Insulin

From the previous discussion it would appear desirable to treat all patients requiring insulin for daily use with a compound variety because of the reduction in the number of doses per day, the economy of insulin effected the improvement in the blood sugar levels, the superior control of ketonemia throughout the twenty-four hours, and the improvement in general health of the patients. The patient already established on regular insulin has considerable to gain by changing to the new variety. The level of carbohydrate in the patient's diet supplies some guide as to what reduction in units of insulin may be expected. For the higher carbohydrate diets there is often little economy. When the carbohydrate content of the diet falls below 100 gm per day, protamine zinc insulin equal to sixty per cent of the

PROTAMINE ZINC INSULIN

Number 213

protamine zinc insulin from day to day to obtain any very consistent results. It is our opinion, after making these studies, that it is better to calculate the dose of protamine zinc insulin corresponding to the dose of the regular insulin that the patient has been taking, and give it as one dose in the morning, providing it does not exceed forty units, and continue this treatment for about a week or ten days. If the total insulin requirement exceeds forty units, it is then advisable to give an additional dose of the regular insulin along with the forty units of the protamine zinc insulin. These two doses are given separately, and in different locations, but at the same time. It is our observation that after one or two weeks, it may be possible to reduce or omit the regular insulin, and in some instances, reduce the dose of the protamine zinc insulin after two or three months.

This has led us to believe that due to the effect of the protamine zinc insulin over a period of months, the diabetic patient shows a tendency to improve in carbohydrate tolerance. It is true that patients who are difficult to regulate and control with the regular insulin are going to be difficult to regulate and control with the protamine zinc insulin. This is particularly true of patients who are subject to insulin reactions. Too much should not be expected of the new insulin, but one should not despair of its use because striking results are not obtained in the first few doses. Frequently patients appear to show loss of tolerance, and are annoyed at the appearance of sugar in the urine and elevation of the blood sugar. After persistence, however, these signs disappear, and the patient is most grateful because of the simplicity of his treatment and the improvement in his general well-being.

DR. HARRY G. JACOBI, *New York City*—When regular insulin was first made available to the profession, the results of its use in diabetes was so striking that very little question arose at the time regarding its indications or contraindications. With the increased improvement and refinement of the preparation, a more rapid action was noticed. This rapidity of action has sometimes been a distinct problem, especially where a more sustained lowering of the blood sugar was desired. In these cases it was found that a certain amount of the insulin was actually wasted because of the rapid action. We have all felt that if insulin could be so modified to insure a slow and uniform rate of absorption, such action would closely simulate the insulin production of the normal pancreas, and thereby eliminate this waste. Various attempts have been made to accom-

plish this result by combining such substances as cholesterol, protamine, calcium, etc. with the insulin. The most practical combination thus far evolved seems to be the protamine zinc insulin. In discussing the various observations reported by different investigators, one notices a certain confusion and disagreement regarding the results obtained. On careful examination of these observations, one notices that unfortunately observations were reported on three distinct preparations, each one of which has a different time reaction. Thus for example, the original investigators reported their results with ordinary protamine insulinate. Later, calcium was added, and a series of reports were made with the protamine calcium insulin. Finally the zinc was substituted for the calcium, giving rise to the present protamine zinc insulin.

The failure to recognize this difference in action of the various preparations can only lead to greater confusion.

The very fact that protamine zinc insulin is absorbed slowly, excludes its use where rapid insulin action is desired. If for example, one expects protamine zinc insulin to effect a raise in the blood sugar, following a meal, one will be disappointed. The planning with the use of protamine zinc insulin is a long-ranged one, where balance is not expected for at least three to four days. During this trial period a certain amount of glycosuria is inevitable and attempts made to eliminate it by giving large doses of protamine zinc insulin or more frequent injection will soon result in hypoglycemia. I think that where immediate action is desired, or becomes necessary as in such diabetic conditions as acidosis, coma, infection or gangrene, regular insulin should be employed. Recently, however, Wilder has reported the effectiveness in using protamine zinc insulin in diabetic ketosis where the long range action of protamine zinc insulin is modified by the more frequent injection of regular insulin with very excellent results, and with a marked diminution in the amount of required total insulin.

Naturally if the error is made of giving protamine zinc insulin at too frequent intervals, or too large doses in an effort to rapidly reduce the blood sugar in a patient with severe or moderately severe diabetes, a condition of prolonged hypoglycemia may result which may cause a fatal outcome, especially in advanced heart disease.

From our experience, we cannot help but feel the following distinct advantages that the use of protamine zinc insulin has over that of the regular insulin.

- 1 It is especially effective in the so-called insulin wasters.

thirty-six or more. This results almost universally in reduction of the number of doses of insulin to one daily. We have found protamine zinc insulin particularly useful in that group of middle aged adults requiring from forty to fifty units daily, which dose may be taken before breakfast as a single injection. We then find that the rearrangement of the diet on what we call a 1-2-3-4 plan works well as a general layout. Dividing the carbohydrate as such into ten portions, one portion is given as a light evening supper about 10 P M, two portions at breakfast, three at lunch, and four at dinner. For example, believing that about 200 gm of carbohydrate as such is best for the average adult diabetic, the division would be twenty gm at 10 P M supper, forty at breakfast, sixty at lunch, and eighty at dinner. This feeds well from the dieticians' standpoint, gives a light breakfast which modern Americans usually would choose to have, a suitable lunch portion, a good dinner arrangement, and an evening meal which fits into the social amities of most of us. Furthermore, it meets the peak of the insulin effect with the maximum amount of carbohydrate. Rearrangements should be made to suit individual conditions and to the individual responses to the protamine insulin mixture causing variabilities in the duration of its action.

We believe one of the most persistent errors in the dietetics of diabetes is the failure to realize that a definite amount of carbohydrate from some source is necessary to a properly balanced metabolism and the production of a sufficient number of calories to carry on the ordinary activities. Furthermore we believe the diabetic is entitled to such a diet and mode of living as will permit him to take his place in society, to follow his occupation, to mix with people, and to eat with his own family the sort of food other people eat. There is no longer need for abnormal types of diet for the diabetic. In fact, such abnormalities are in the end detrimental. Anything that makes for his comfort and inconspicuousness adds to his general well-being and prolongs his life. To withhold carbohydrate like a conscientious objector, then feed excessive amounts of protein and fat with the guilty knowledge that the patient will pull the carbohydrate fraction out of some of this other food stuff, throwing away the degraded balance, is begging the question. Protein that serves to supply carbohydrate cannot also serve as protein. If it were better to feed that amount of carbohydrate which must be had that he may have it from the normal, least expensive source—least expensive in food cost, least expensive in metabolic effort—

then he need not take it by wasting his own body unless it has been deemed necessary that he should do so, and only such amounts of protein and fat need be supplied as should be in any ordinary diet. When such a diet is pursued even with the regular insulin, a smoothing and a cushioning effect is obtained. Should the patient temporarily need more carbohydrate, he may obtain it by breaking down the protein or the fat temporarily just like any other individual. Ordinarily, however, he obtains the necessary carbohydrate for fuel purposes from carbohydrate as such.

The combined effect of all these is to give a reasonable diet through the feeding of ordinary foods including all the carbohydrate the ordinary person would choose to take except for the elimination of sweets. With protamine zinc insulin in the morning before breakfast, the exact timing of meals and their burdensomely meticulous apportionment becomes unnecessary, the accommodative powers are increased, and the diabetic closely approaches ordinarily correct living, consuming a dietary any healthy person might accept comfortably and profitably.

DR. WILLIAM WALLACE HALL, *Watertown*—My part in this discussion is to report on the use of protamine zinc insulin in regulating diabetic patients, who are insulin sensitive, that is, those patients who are subject to insulin reactions while using the regular insulin.

Two cases have been carefully studied. The first, a woman forty-seven years of age, who gives a history of diabetes for twelve years, the other a woman of fifty-nine, who has been a diabetic seven years. On several occasions these patients have had severe insulin reactions, especially at night, at times being unconscious. The former was taking twenty units of the regular insulin in the morning, and fourteen units of the regular insulin at night. The latter was taking twenty-eight units of the regular insulin in the morning, five of the regular insulin at noon, and twenty of the regular insulin at night. Blood sugars continued to be found above 250 mg %, when the blood was examined at 11 A M. While in the hospital for this study, the urine was examined every three hours for sugar and acetone, and the blood sugars made at 8 A M, and 4 P M.

The findings in these two cases were quite similar.

The lesson we learned in studying these two cases over a period of ten days, is that the patients tend to run high blood sugars in the late afternoon, and low blood sugars during the night and early morning, and that it is difficult to regulate the dosage of

IRRITATIVE THERAPY OF SCHIZOPHRENIA

Practical Application and Theoretical Considerations

EMERICK FRIEDMAN, M D, M S, Ossining

The interest of the psychiatric world in the Camphor-Metrazol therapy has been mounting steadily since the original work of Meduna.¹ The increasing number of mental hospitals employing this biotherapeutic method of attack on the schizophrenic disease process will attest to the fact that this procedure has become indeed a fascinating and absorbing study. It is the purpose of this paper to present, aside from statistical material,* certain directions for further intensive, cooperative research in neurophysiological and psychological interrelationships. It is felt that as time goes on, there will be brought forth much more data on this score, reinforcing or even reintegrating a correlated approach on the problem physiologically and psychodynamically. In view of reports now in preparation at Stony Lodge, only a skeletal survey is possible in the scope of this presentation.

Since the rendition of the first paper on the subject of the irritative therapy of schizophrenia,² certain interesting, and, it is believed, pertinent data has accumulated. It was brought out at that time, that it is possible to think, theoretically, of schizophrenia as a correlate of a sluggishness of general body metabolism.³ There was also brought out the presumption that in schizophrenia, there might be (again theoretically) a physiological barrier to certain associative pathways, that would tend to become more and more impenetrable as the disease progresses. If, however, a regime were set up that would cause a stimulation—irritation—of the whole central nervous system, these so-

called barriers might be broken up, allowing proper thought processes to emerge and take their place in the carrying on of thought volitional-motor activities.

Through objective observations of therapeutic remissions in cases of schizophrenia, it was noted that those patients who underwent deeper states of delirium, confusion as well as grandmal reactions, best retained their apparently recovered mental status. It was furthermore mentioned previously, that the chief reactions to camphor were delirium and confusion, with but relatively infrequent major convulsive reactions. On the other hand, Metrazol produced active convulsions at the desired intervals, but it usually took some time to develop any degree of delirium—some cases never actually reaching that stage. It was felt, that if the two drugs were combined, both of the objectively desired effects could be produced. Two further points that might be mentioned are

1 If the confusion which developed under camphor were deep enough, the terror which usually besets the patient receiving Metrazol might in a sense, be muffled, if the Metrazol injections followed a course of camphor.

2 It was noted that camphor had a more profound and more prolonged effect from the standpoint of the patient—the patient suffered more from the intoxication of camphor, while the Metrazol reaction, even though more dramatic and conclusive, was of short duration. The following technic was therefore adopted

I Technic

A Alkalinization It is preferable to place the patient on a standard alkaline diet for about a week preceding the therapy proper. This must, furthermore, be kept up throughout the entire treatment. Sodium bicarbonate, two tablespoonsful three times daily, or its equivalent, is administered throughout the treatment. The urine should be tested daily for alkalinity.

* Cases treated on the Neuropsychiatric Services of the Buffalo City Hospital, Buffalo. The author wishes to express his acknowledgment and sincere appreciation to Dr Alfred L. Ulrich, Resident Neuropsychiatrist of the Buffalo City Hospital for his aid in compiling the case material and carrying on the prescribed therapy since July 1, 1937.

2 It avoids the necessity of the patient taking a regular dose of insulin at an early hour of the morning as 3 or 4 A M

3 Severe diabetes with marked fluctuations in the blood sugar are more easily steadied by that combination of therapy, because of the fact that the carbohydrates are more completely oxidized than by a similar dose of regular insulin

4 There usually results after a varying period of use, a marked reduction in the total number of insulin units necessary for the control of the diabetic condition together with an increase in the well-being of the patient

5 Surgical wounds as well as infections seem to get along better with the combined form of therapy

AUTOMOBILE INJURIES

To emphasize the need of studying the modern surgical problem of automobile injuries Claire L. Straith, Detroit (*Journal A M A* Sept 18, 1937), points out that during the past year, 38,500 deaths resulted from automobile accidents alone. The total number of nonfatal accidents was 1,340,000, of which 110,000 resulted in permanent disability. Present figures indicate a twenty-eight per cent increase in deaths for the present year. If these figures are compared with those showing the progressive decline, year by year, in mortality and morbidity from diseases and other hazards, the contrast is startling.

What a hue and cry would be raised if typhoid or smallpox were to bring a similar epidemic of death or disability, or even a much lesser one! In its most destructive years, the "white plague" was hardly more devastating.

Despite the physician's best efforts, it must be admitted, unsightly scars will occasionally develop. These should later be carefully excised. The time for secondary plastic procedures is at least two months after healing has taken place. The subcuticular suture is recommended for closure to obtain minimal scar formation. Crushed noses and depressed cheek and frontal bones also require attention. Transplants of rib cartilage may be used to fill in these defects.

Severed noses, especially in males, are distressing deformities. Attempts should be made to reconstruct missing portions. Complete nasal losses provide even more urgent indications for restoration. If a good lining is present or easily provided, Wolfe grafts

may be used to good advantage if the loss is not too extensive. Larger losses can be replaced only by pedicle grafts. The forehead flap method is best suited to women because it provides hairless, well matched skin. The resulting scar on the forehead is readily concealed by the hair-dress. In men, however, the scar on the forehead is almost as obnoxious as the nasal disfigurement itself. Hence a flap formed from the skin just below the ear and overlying the sternocleidomastoid muscle is preferable. This is generally quite free from hair and closely matches the facial integument. The graft is brought to the face via a tube pedicle attached primarily to the region of the sternal notch. From this point it is secondarily attached to the nose.

Many other medical aspects of the problem of motor car accidents need earnest consideration. One of the most pertinent of these concerns the mental and emotional health of the many victims. Above and beyond the physical suffering which they must endure as a result of horrible injuries is the mental agony which lasts throughout life in the presence of facial disfigurements, however slight. Complexes and near psychoses brought about by brooding over facial disfigurements have removed many of these unfortunates from active social and business activities. That their worries are not unfounded, on the whole, is borne out by the fact that employers place a high premium on good appearance in selecting employees who must meet the public.

"How large a part these injuries have in contributing to the ranks of the unemployed and unemployable can only be conjectured."

'HELPING THE SUCKER RACKET'

That is the comment of the *Ohio State Medical Journal* as it notes that in an opinion handed down July 22, the Supreme Court of New Jersey held that blood pressure is not a disease and that its determination is not restricted by law to physicians, sustaining a decision of the Atlantic County

court, acquitting one Max Plager, who takes the blood pressure of his customers in a concession on the Boardwalk at Atlantic City, and who had been prosecuted by the State Board of Medical Examiners on the charge that he was practicing medicine illegally.

IRRITATIVE THERAPY OF SCHIZOPHRENIA

Practical Application and Theoretical Considerations

EMERICK FRIEDMAN, M D, M S, *Ossining*

The interest of the psychiatric world in the Camphor-Metrazol therapy has been mounting steadily since the original work of Meduna¹. The increasing number of mental hospitals employing this biotherapeutic method of attack on the schizophrenic disease process will attest to the fact that this procedure has become indeed a fascinating and absorbing study. It is the purpose of this paper to present, aside from statistical material,* certain directions for further intensive, cooperative research in neurophysiological and psychological interrelationships. It is felt that as time goes on, there will be brought forth much more data on this score, reinforcing or even reintegrating a correlated approach on the problem physiologically and psychodynamically. In view of reports now in preparation at Stony Lodge, only a skeletal survey is possible in the scope of this presentation.

Since the rendition of the first paper on the subject of the irritative therapy of schizophrenia,² certain interesting, and, it is believed, pertinent data has accumulated. It was brought out at that time, that it is possible to think, theoretically, of schizophrenia as a correlate of a sluggishness of general body metabolism.³ There was also brought out the presumption that in schizophrenia, there might be (again theoretically) a physiological barrier to certain associative pathways, that would tend to become more and more impenetrable as the disease progresses. If, however, a regime were set up that would cause a stimulation—irritation—of the whole central nervous system, these so-

called barriers might be broken up, allowing proper thought processes to emerge and take their place in the carrying on of thought volitional-motor activities.

Through objective observations of therapeutic remissions in cases of schizophrenia, it was noted that those patients who underwent deeper states of deliriform confusion as well as grandmal reactions, best retained their apparently recovered mental status. It was furthermore mentioned previously, that the chief reactions to camphor were delirium and confusion, with but relatively infrequent major convulsive reactions. On the other hand, Metrazol produced active convulsions at the desired intervals, but it usually took some time to develop any degree of delirium—some cases never actually reaching that stage. It was felt, that if the two drugs were combined, both of the objectively desired effects could be produced. Two further points that might be mentioned are:

1 If the confusion which developed under camphor were deep enough, the terror which usually besets the patient receiving Metrazol might in a sense, be muffled, if the Metrazol injections followed a course of camphor.

2 It was noted that camphor had a more profound and more prolonged effect from the standpoint of the patient—the patient suffered more from the intoxication of camphor, while the Metrazol reaction, even though more dramatic and conclusive, was of short duration. The following technic was therefore adopted:

I Technic

A Alkalinization It is preferable to place the patient on a standard alkaline diet for about a week preceding the therapy proper. This must, furthermore, be kept up throughout the entire treatment. Sodium bicarbonate, two tablespoonsful three times daily, or its equivalent, is administered throughout the treatment. The urine should be tested daily for alkalinity.

* Cases treated on the Neuropsychiatric Services of the Buffalo City Hospital, Buffalo. The author wishes to express his acknowledgment and sincere appreciation to Dr Alfred L. Ulrich, Resident Neuropsychiatrist of the Buffalo City Hospital for his aid in compiling the case material and carrying on the prescribed therapy since July 1, 1937.

to litmus The fluid intake is set at a minimum of two liters per day No sedatives should be given for the period of treatment

B Camphor This phase is kept up from one to three weeks (It will be shown in a subsequent paper that three weeks' time is better) The camphor is administered in the form of the freshly prepared, sterile, twenty-five per cent oily solution Injections are given intramuscularly twice daily The usual technic for antiluetic bismuth therapy is adequate, with the additional skin preparation with tincture of green soap, iodine, and alcohol The dosages are regulated according to the following protocol The initial dose is four gm of the amorphous camphor, and the subsequent doses are increased at the rate of one gm per day, so that each injection per day is increased by 0.5 gm If convulsions occur at any given dose, the injections are omitted the following day, and if the convulsion occurred after the first injection, the second injection is omitted likewise, on that day In this manner, the medication is given at the most, to provoke only one convulsive episode every other day The injections are resumed with the lapse of a day, as directed above, starting, however, with the convulsive dose The maximum dose of camphor is set at fourteen gm twice a day This might be more clearly understood in outline calendar form

COURSE OF INJECTIONS

Day	8:00 A M Dose	Reaction	5:00 P M Dose	Reaction
1	4.0 gm (16 c.c.)		4.0 gm. (16 c.c.)	
2	4.5 gm. (18 c.c.)		4.5 gm. (18 c.c.)	
3	5.0 gm. (20 c.c.)		5.0 gm. (20 c.c.)	
4	5.5 gm. (22 c.c.)	Grandmal	Omitted	
5	Omitted		Omitted	
6	5.5 gm. (22 c.c.)		5.5 gm. (22 c.c.)	
7	6.0 gm. (24 c.c.)		6.0 gm. (24 c.c.)	
8	6.5 gm. (26 c.c.)		6.5 gm. (26 c.c.)	
9	7.0 gm. (28 c.c.)		7.0 gm. (28 c.c.)	Grandmal
10	Omitted		Omitted	
11	7.0 gm. (28 c.c.)		7.0 gm. (28 c.c.)	
12	7.5 gm. (30 c.c.)		7.5 gm. (30 c.c.)	

It may be found that not even a single convulsion will occur throughout the duration of the camphor therapy This is not to be regarded as a source of wonderment because most individuals will rapidly develop a type of tolerance to the drug It is well, however, in these cases, to make a thorough check-up of the alkalinization and the fluid intake It has been found by the writer that if, for example, the fluid intake and the alkali ingestion were brought up to the required amounts, con-

vulsions would ensue within one or two days, whereas previously, there might have been some laxity and these factors were not noted, and convulsions had not occurred Whether or not convulsions occur with camphor, the therapeutic value is still prominent as will be taken up later

C Metrazol Metrazol is employed in a ten per cent aqueous solution and given intravenously once every other day This phase of the therapy may be started within a day or two after the camphor The initial dose is 0.5 gm Subsequent doses are increased at the rate of 0.1 gm each injection, depending upon the occurrence of grandmal or so-called petitmal attacks following injections If a typical, violent convulsion occurs after a given injection, the next injection does not need to be increased It is well to point out again, that a constant check-up of the alkalinization and fluid intake is necessary to produce as many grandmal reactions as possible without too rapidly increasing the dose Another point to be emphasized is that for purposes of standardization of each dose, the Metrazol should be injected as rapidly as possible

A block of therapy may be considered as having been completed when a total of twenty-five to thirty grandmal reactions have been obtained This includes the grandmals that have occurred during the camphor therapy

Although the contraindications were mentioned in the previous paper, it would be well to list them again for the purpose of emphasizing that the procedure may not be conducted without any fear of danger (1) Evidence of cardiovascular disease (2) Acute febrile infections (3) Menstruation (4) Abnormalities of the laboratory findings (5) History of head trauma with subsequent unconsciousness A point that may be brought up in this connection is that if a patient displays unilateral or asymmetrical motor phenomena in the convulsive reactions *per se*, a very careful neurological re-estimation of the patient should be made, in order to rule out the possibility of a neurologic disease

II Rationale and Observations

It is only too apparent that the regime consists of inducing a toxic delirium, punctuated by convulsions It was noted

previously, that in all likelihood, this is not merely "shock therapy," but that a continuous irritation of the central nervous system is brought about, starting even with alkalinization and hydration, and kept up to a relatively high degree with camphor and Metrazol. The analeptic nature of the two drugs has been known for some time, but the therapeutic application of the "epileptic state" in schizophrenia was first employed by Meduna. However, the originator himself has expressed doubt whether or not the actual convulsive reaction is the real agent in producing the remissive changes in the psychosis. With added experience, this point will no doubt, be cleared. It has been found that remissions will occur after a course of camphor, even without a single convulsion of any type, and that remissions will occur after Metrazol without any deliriform manifestations, but these remissions are not as stable as those that have shown both reactions. The concurrence of epilepsy and schizophrenia, although of relative infrequency, has been reported⁴ and since this subject has been presented, many individual workers have informally described their experiences on this matter to the writer. It becomes more evident that the real effectiveness of the therapy does not rest entirely upon the biological antagonism expressed by Meduna, but upon a more subtle and deeper set of factors, for which one will probably have to seek in the neurophysiological, metabolic, and endocrine make-up of the individual, with all of the respective psychocorrelaries. The descriptions which follow will point out certain prominent events occurring during therapy. An appraisal of these will be given later.

1 *The camphor reaction with grandmal.* The patient usually complains of the pain of the injection and subsequent massaging. The pain wears off in about one hour. He looks around, the expression of ecstatic or distant preoccupation soon changes to one of increasing anger or anxiety. Restlessness increases, if the patient is allowed, he will pace up and down the room, or sit down only to jump up at frequent intervals. It is soon sensed both by the physician and the patient that something unusual is going on. If the patient is in mild restraint, he begins gradually to look at the bands and to pick at them. Agitation mounts and then a feverish pulling and twisting are noted. Within

an hour or so, the patient may make a sudden impulsive dash for the window or wall, even attempt to burst through them, head first. He will strike out at the attendants or tug at the restraint, pounding on the bed with his fist and bouncing up and down. Nausea, emesis or retching are frequent, and may be kept up at intervals throughout the time of treatment. The speech undergoes changes from a whining or pleading to a demanding roar of protest, becoming more and more incoherent, bringing out usually a mass of delusional data. Extreme fear is soon portrayed in the facial expression, and this mounts to a visage of terror. The patient may actually remark that he is under diabolical influences. Isolated twitchings of the extremities, facial muscles, or trunk are then noted. These increase in frequency and intensity in the space of a half hour. At times, a tonic element is intermingled with these twitchings, giving a picture of a type of athetosis. Suddenly, the patient appears as though transfixed. His eyes open wide, a more terrified expression than before appears, the mouth is opened wide and at this time, the watchful attendant has an opportunity to place a firm, cotton gag into the mouth between the molar teeth. The skin blanches and then flushes, an inspiratory scream is emitted and at the same time, the extremities are tonically extended, the trunk undergoes a severe sudden tonic spasm, resulting in an opisthotonos or orthotonos.

This, the tonic phase, is so intense that the bed as well as the body vibrates. The clonic phase ensues usually in one-half minute and assumes one or two patterns. The first is that of a so-called "release" type in which the tonus paroxysmally diminishes, allowing partial relaxation, only to appear again. The second type is that of a so-called "discharge" clonus in which there is apparently a sudden change in the two phases and the clonic movements assume patterns of sudden nerve excitations. This phase lasts one-half a minute and subsides either suddenly or gradually. All of the visible muscles of the body seem to be involved in both the tonic and clonic phases. The skin displays prominent goose-flesh through the tonic stage, but becomes lividly cyanosed or assumes a ghastly pale color at the end of the clonic stage. The respiration which has been practically suspended during the above phase, is resumed at the most, within a minute, and invariably begins with a harsh stertor wherein much foaming saliva is expelled. At times there may be a brief period of coughing, also at this time sinus arrhythmia is present and lasts for one or two minutes. The pulse gradually becomes more forceful and regular. The general pic-

ture that the patient presents, is one of thorough exhaustion. He is usually covered with perspiration and is panting for as much as five minutes. During this time, the phase of automatic restlessness begins and is kept up for as much as an hour. The patient slowly begins to lift up his extremities in the flexed position and may assume postures and maneuvers of fetal positions, coitus, and masturbation. Picking movements with the hands in various locations of the body are frequently encountered. Various stroking or "washing" movements are likewise noticed. Gradually, the hands encounter the face and the protruding gag. This is picked at for a short while and then incoordinated attempts are made to pull the gag out of the mouth, keeping the mouth closed, resulting in a peculiar gesture wherein the patient is tugging at the gag with both hands, ripping it with his teeth, and even uttering guttural growls at the same time. Very often, the gag is torn to shreds and the patient will chew at these shreds, actually swallowing them. If the attendant forcibly extricates the gag, the chewing movements will be kept up, the patient mumbling all the while.

Another series of movements that is often encountered, is that of attempts to run while in the supine position, at the same time thrusting out the hands. If the patient's feet encounter the wall, a picture is soon presented of attempting to crawl up the wall, head down. Many similar movements have been observed, all of which are indicative of a type of vertiginous activity. This is further evidenced by nystagmoid movements, rolling of the head and definite ataxia in all attempts to grasp at objects or to touch various parts of the body. Another interesting phenomenon observed in this respect, is that, if the patient were to be called by name at this time, his gaze in response would be turned in an entirely different direction. This phase gradually subsides and the patient will apparently fall asleep for a half to several hours. The status of the reflexes may be outlined at this point:

(a) *Tonic phase* The pupils remain dilated, the corneae are anesthetic, there is a permanent Babinski. Tendon jerks are impossible to elicit.

(b) *Clonic phase* The pupils become more contracted, the corneae are still apparently anesthetic. The Babinski becomes paroxysmally positive with the clonic jerks. Tests of tendon jerks are unreliable. The pupils do not react to light in either of these stages.

(c) *Automatic phase* The pupils show great lability but are reactive. The corneae are rapidly sensitive. All tendon jerks are greatly exaggerated, positive signs of pyramidal tract irritation persist for as long as an hour after the clonic phase. There may be found definite myotatic irritability after the clonic phase, and

this subsides within a few minutes. At the end of the automatic phase, the tendon reflexes are frequently hypoactive, or absent. Upon awakening, the patient is dazed and confused for a length of time. The amnesia may include the entire foregoing treatment procedure. Repeated convulsions occasionally occur with camphor, but these usually begin a few minutes after the clonic phase of the preceding reaction.

2 *The camphor reaction without a grand-mal* The picture of this closely resembles the foregoing. The pattern of mounting anxiety is, however, frequently so severe that at times, it may amount to a real fury. The duration is usually longer. Certain individual and characteristic differences, are noted in that instead of a fury, the patient will undergo an uncontrollable episode of agitated weeping. In all cases, however, there is given the definite impression that the patient is transferring his preoccupations with accessory symptoms to a serious consideration of what is happening to him. Obviously, certain delusional elements of torture by the injection and medication are verbalized.

3 *The Metrazol grand-mal reaction* This reaction is entirely similar to the grand mal reaction under camphor. The process, however, takes place with almost lightning rapidity. The patient is usually given the injection before a meal. He is placed in bed without a pillow. Frequently, if the patient has had several of these injections before, he will begin expressing his fear of the treatment, or else he will be so frightened that he will not be able to talk nor even to perform such simple acts as undressing. He will usually be pale and have almost a cold, clammy skin even before the injection has been started. The administration of the drug usually takes about a second or less for five c c. The patient is almost instantaneously transfixed with terror. There is practically always an aura of olfactory, visual or auditory character. The patient (as found later by personal interview) experiences a suffocating odor and taste of some aromatic substance, "something like chloroform" which makes him cough and snatch at his throat. His head begins to feel light, or else there is a pounding or expanding sensation. Varicolored visual hallucinations of rapidly moving objects and often a torrent of auditory hallucinations rush at him. These features are, of course, colored to a great extent by vertiginous symptoms in which the people in the room, or the patient himself, seem to vibrate, multiply in number or whirl about. The auditory picture changes rapidly to a roaring in the head and the patient loses consciousness at the onset of the tonic phase. The remainder of this picture is very similar to that de-

scribed in the camphor reaction. It is noted that incontinence is more frequent in the grand mal reactions produced by Metrazol as well as ejaculation without erection. Both of these phenomena occur usually at the end of the clonic phase. The automatic phase usually is of shorter duration than that observed under camphor. It is very rare to find repeated convulsions under Metrazol, although they are known to have occurred. Infrequently, there is noted a very severely restless automatic phase accompanied by screaming and attempts at self-mutilation.

4 *Metrazol petit mal reaction.* This reaction, upon superficial observation, may almost be said to consist of an extended *aura*. Immediately upon receiving the injection, the patient undergoes the same premonitory symptoms as described above. He will display tremors, or slight twitchings of the facial muscles—especially the eyelids—and extremities. He may suddenly sit up and wave his arms and hands in front of his face as though in an effort to protect himself. Upon being placed in the reclining position again, repeated attempts to sit up might be encountered. The twitchings and flutterings of the eyelids may continue for an hour. There might be the same subjective sensations as noted above. It is with great difficulty that the patient can be made to express his sensations at this time. If urged to talk, he frequently replies gruffly or beseechingly to be left alone, or to be allowed 'out of this'—giving the impression that he felt as though he were hemmed in or tied down.

A very interesting finding, frequently encountered after the Metrazol petit mal, is one in which the patient will assume almost typical catatonic postures even in spite of the fact that he may not have been at any time catatonic during his illness. These postures may be maintained for several hours. Again during this time, the patient might cry out "get me out of this." In most instances, the patient will be more deeply confused and for a longer period of time than after the grandmal. Most patients display more irritability and greater sulkingness, or even become more aggressive after a petit mal.

It is desirable to emphasize the fact that all sedatives should be excluded during treatment, no matter how violent a picture the patient presents.

III Results and Clinical Course

The following data are compiled from the therapeutic results observed in forty cases admitted to the Neuropsychiatric Service of the Buffalo City Hospital dur-

ing 1936-1937. The first twenty cases were reported in the previous publication. In these cases, follow-up data of longer duration are herewith presented and twenty additional cases reported upon.

In the first twenty cases, illustrated in Table I, the duration of illness ranged from less than one month to over six years. The types of cases as noted were varied. The fifteen cases from the first group which had been designated as "much improved" in the previous publication, to this date, display the following favorable characteristics of what might be called true remissions, good social adjustment, sound financial adjustment, and no evidences of psychosis. The follow-up data in these cases cover at least a period of four months. In seven cases, this follow-up amounts to a period of almost one year. The fate of the five cases which were regarded at the time of the previous paper as either "unimproved" or "but moderately improved," i.e. as regards behavior, shows no particularly remarkable change in reference to our subject. It may be said that the writer has had intimate and social contact with several of the remission cases during this time of follow-up, and a very eager rapport was in evidence.

In the second twenty cases, (Table II) whose duration of illness ranged between less than a month to as high as twenty years, in one case, ten years in another, and whose follow-up covered a period of less than three months, display a maintenance of the ratio of successful treatments. In view of the short time of follow-up, it cannot be stated with certainty what the outcome will be. Taking this into consideration, the results were found to be as follows. Sixteen of the second group of twenty cases, displayed normal behavior, good social and financial adjustment, and no evidence of psychosis. Two cases were entirely unimproved, two cases showed a great improvement in behavior, a reasonable enough social adjustment so as to be permitted to remain at home, but still revealed latent evidences of psychosis. Of the two cases which remained unimproved, one definitely did not have enough treatment in proportion to the duration of his illness, the other had well-recognized psychopathic constitutional traits which had been apparent

SCHIZOPHRENIA

Number 211

throughout his life. Also, it was learned from the state hospital to which he was committed, that no evidence of actual psychosis could be demonstrated.

From the foregoing results in both groups of cases, it was found that thirty-one out of the forty treated cases, showed definitely remissive changes which we must wait upon before calling them true remissions. Of the thirty-one cases, three suffered relapses which in all sincerity, might be attributed to insufficient treatment.

Two brief case reports follow which point out the general clinical events which transpired in the arbitrarily designated two major types of the psychosis.

CASE 1 (The so-called active, agitated or furious type) N A, female, age thirty, Latin descent. For the past three years or more, the patient has had increasing difficulty in adjustment to home and social conditions. During all of this time, she has expressed fears of dying, imminent danger to her family, and diabolic influences. Ideas of reference about visitors and relatives were apparent. Many noisy, excited reactive episodes had occurred in which she was rather aggressive. She was admitted during one of these episodes. In the hospital, her condition was found to be as aforementioned. Reactive agitation, however, was a prominent feature. A diagnosis of the paranoid type, predominantly of the paranoid type. Under irritative therapy within four grand mals, her agitation and reactivity to accessory symptoms ceased. Instead, the patient expressed extreme fear of the injection and on the "free" days, she gradually became interested in what was going on around her, becoming rather attached in a friendly way to the other patients receiving treatment. After ten grand mals, she became less alert and seemed constantly bewildered, upon questioning, her recent memory showed evidences of fragmentation with some attempts at confabulation to fill in the gaps. Here her entire demeanor underwent a transition from activity to stolid confusion. She was released in about six weeks, even though displaying this confusion. Two weeks after her release, she telephoned and maintained a spontaneous, alert, and pleasant conversation. Reliable reports from close relatives reveal that the patient had adjusted herself very nicely at home, was eager for social encounters, planning to go to work, and displayed no evidences of psychosis.

CASE 2 (The so-called sedentary, quiescent, stuporous type) S L, female, twenty

years of age, Teutonic descent. For about three weeks prior to admission, the patient had appeared depressed, had become progressively uncommunicative, undesirable eating and for several days before admission, assumed a mute, negativistic, catatonic posture, refusing all food and drink. She remained in this state for three weeks after admission, and the usual measures for the administration of nourishment and fluids were instituted. With the second grand mal reaction, the patient got up, immediately occupied herself with personal care, and talked to her fellow patients and nurses as though nothing unusual had happened. From that time on, she was very cooperative in ward routine, mingled very well with all the other patients, and frequently begged that we stop the injections because she was not "sick" any more. Between the tenth and fifteenth grand mal reactions, she displayed flagrant signs of memory disturbance and became quiet, almost sedentary in her behavior, although if she were requested to perform a task, she would immediately execute the order. She was released while still confused. Within the next two months, she was seen and her family contacted. The reports and impressions were definite that she was well-adjusted socially, gave no evidence of psychosis, and had obtained work.

Discussion

In the foregoing two cases, the average clinical course is demonstrated. In the quiescent or stuporous variety which includes the sedentary, preoccupied, paranoid patient as well as the catatonic, the first change under therapy is that of awakening and becoming aware of environmental conditions. It has been noted that these changes might be dramatic and be associated with a considerable amount of excitation and aggressiveness. In any event however, after about ten to fifteen grand mals the patient will become dull, confused apathetic and prone to display confabulation or silly witticisms to cover up memory defects which invariably occur with this amount of treatment. In the excited types which include the furious catatonic varieties, the outstanding change at the beginning of treatment is that of pacifying the behavior. During this stage the patients will frequently state that they will "behave themselves" if they do not receive further treatment. A quiet, worried picture is presented. From this point

on, there develops progressive confusion and apathy

IV Theory and Comment

From the foregoing, many ramifications of theory are possible. The only distinct and definite starting point lies in the fact that we are treating the disease entity, schizophrenia, whose etiology and morphology are still enigmatic with a regime which produces profound irritation of the central nervous system. The physical picture brought about by this procedure consists essentially of a toxic delirium, punctuated by convulsions.

Certain phases of this problem may be held as responsible for bringing about remissive changes. It cannot be stated which part of these reactions is the real factor. Certain it is, that much work is laid out for the future. It is known that the drugs employed have their primary action as medullary irritants.⁵ In this way, practically all of the vital centers are stimulated, or irritated.

Suspension of respiration causing deep cyanosis of the entire visible portions of the body may have profound bearing upon the immediately apparent improved clinical picture in many cases. There has been some work on the problem of oxygen status with reference to certain mental states.⁶ From a survey of this data, it is found that not only does diminished oxygen tension of the respired air change the mental picture of a psychotic patient, but also will produce many phenomena in the normal individual that may at times mount to a condition of hallucinations and delusions with disturbances in association. Furthermore, severe anoxemia will produce violent psychomotor excitation. Certain parallelisms may be drawn between the deep cyanosis during therapy and the rapid improvements often observed in schizophrenic patients undergoing anoxemia.

The rapid changes in blood pressure and volume as well as pulse rate, are only too apparent in the entire reaction picture. These changes in the vascular bed and nutritional supply to the brain cells may cause just enough variation in the existing metabolic equilibrium to reverse whatever tendency there existed in the schizophrenic condition. Another fea-

ture that is brought to bear is that of the gross disturbances of vestibular function during the reactions. These, as have been pointed out above, are recognizable from many signs presented subjectively and objectively. The factor of giving violent motion to a stable set of accessory symptoms and the addition of vivid symptoms from neurogenic excitation, must have a profound effect upon the schizophrenic individual.

Many of these sensations are not forgotten, the patient may recall them if he attempts to reorganize his schizophrenic pattern of behavior. The apparent subjective sensations of various stages of dysequilibration brought on by actual neurogenic excitation, may provoke a strong attempt on the part of the organism to reintegrate associatively healthy motor patterns—a neurologic redirection, as it were.

The picture of vegetative nervous system responses presented by the patients undergoing camphor and Metrazol therapy, is distinctly problematic. There is evidence from the clinical description given, that the entire system is stimulated for example, rapid changes of skin color, cutis anserina (goose flesh), profuse sweating, changes in the cardiac rate and blood pressure, stimulation of the entire alimentary tract, bladder incontinence, and ejaculation. How much, and which of these phenomena have any bearing on the remissive changes can only be a matter of conjecture. It is true that vital processes are involved in this, and that when the organism receives stimulation here, the response calls forth every conceivable and available defense mechanism. Perhaps the result assumes the characteristics of an effort of readjustment of the vegetative nervous system (which has been dormant?) to meet actual needs and to protect the organism in reality, whereas previously the needs of the organism had been fulfilled in an autistic state which necessitated no autonomic responses.

The other responses elicited are likewise problematic. The automatic assumption of fetal postures—even associated with infantile speech—the enactment of various movements of coitus, masturbation, and other maneuvers indicative of various lower erotic levels, undoubtedly

SCHIZOPHRENIA

November 1, 1937]

play a significant role. Similarly, the stroking, picking, washing or running movements—often preceded by a brief period of actual rigidity at the very end of the clonic phase—are of importance. There is presented to us a picture of what might be termed decerebration which gradually passes through one developmental level after another and then arrives at consciousness. The reappearance of reflexes parallels this. One would surmise that a type of developmental momentum were going on, and that this would

proceed in the more natural directions of neurophysiologic integration. The intrinsic biochemical changes under therapy were found to be without any special characteristics as far as ordinary laboratory findings were concerned, but this will undergo further investigation. Time and space are not sufficient for a proper estimation of the psychodynamic or psychobiologic correlates of the foregoing events, but these are now prepared and will be brought forth in another presentation.

TRACING SYPHILIS THROUGH COMMON AILMENTS

A Benson Cannon, New York (*Journal A M A*, July 31, 1937), points out that the present study was originally conceived as a part of a larger one dealing with the accomplishments of arsphenamine in the treatment of syphilis of all stages. For this purpose a systematic record was kept of all adult patients admitted to the department of dermatology from the spring of 1935 to the spring of 1937 whose ultimate diagnosis was syphilis.

In the course of this study it became increasingly apparent that a large proportion of the patients so admitted arrived in this department by accident rather than by design, having presented themselves originally for some complaint totally unconnected with syphilis—at least in their own minds and frequently also in the opinion of the admitting physician. The approximately 600 cases of syphilis recorded to date are unselected, then, as regards latency and represented all syphilitic patients who were treated with arsphenamine during any or all of this period. It leaves out of account those who received only intramuscular injections and/or silver arsphenamine. Among these 600 cases there were 300-odd admissions in whom active syphilis was not at first suspected.

Not until commonplace injuries failed to heal after weeks or months of treatment

by ordinary measures were some of these patients discovered to have a positive Wassermann reaction and some a history of a previous infection, overlooked or passed by as irrelevant to the present complaint. The mystery of the slow healing operative wound—even after the extraction of a tooth—is often solved by the simple procedure of taking a blood test.

It was found that a surprisingly large proportion of these patients had presented as their chief complaint some ailment commonly encountered in general practice under the names of gastro-intestinal disorders, chronic disorders of the respiratory tract, urinary symptoms, gynecologic ailments and miscellaneous arthritis, diabetes, hernia, goiter and the like. The present report attempts to describe, in a selected group of cases, the methods by which other causes were eliminated, and the symptoms were traced to a syphilis heretofore either unsuspected or supposedly inactive.

Symptoms which brought patients to the clinic, the diagnostic procedures, including laboratory tests, x-ray examinations and pathologic changes, the evidence for syphilis and the treatment and its results are described by the author in the hope that this approach, by symptoms rather than systems (the usual textbook method), may prove of considerable interest and practical value.

COMBATING SYPHILIS AND GONORRHEA

The New York City Plan

JOHN L. RICE, M D, *New York City*
The Commissioner of Health, New York City

Soon after I took over the duties of Commissioner of Health of New York City, I began to consider the problems of syphilis and gonococcus infections in the huge population committed to my care by Mayor LaGuardia. These diseases have been considered special problems for large cities. Whether or not the prevalence of syphilis is greater in large cities than in smaller towns and rural districts, it cannot be doubted that great centers of population such as Chicago and New York offer exceptional opportunities for a scientific attack on this health problem. If we can devise means successfully to combat syphilis and gonorrhea in New York City, we would, under one plan and one jurisdiction, solve the problem for seven and one-half million people, or more than six per cent of the whole population of the United States.

I would like to mention three special studies which contributed to the development of our program in New York City, studies which helped us to find a sound scientific foundation for a practical program.

Since the construction of a scientific program for combating syphilis in a city as large as New York was in many ways an entirely new undertaking in America, it was our desire to profit by the practical experience of other cities and countries. For this reason, His Honor, Mayor LaGuardia, appointed a commission to study and report on the methods now employed in the Scandinavian countries and Great Britain. I had the honor to serve as chairman of this commission with representatives from the New York City and New York State Medical Societies. The present Surgeon General of the Public Health Service joined the commission and participated in its studies. The commission spent the summer of 1935 in the Scandinavian countries and Great Britain, and returned to the United States very much

impressed with the work which has been done in the countries visited. I regard this study as so important that I would like to give you a brief resume of our findings.

Syphilis has declined markedly since 1920 in each of the four countries studied. In the Scandinavian countries it has become almost a rare disease. In these three countries, with a total population of 13,700,000, health authorities were notified of less than 1,600 cases in 1933. Careful inquiries and corroborative evidence convinced the Commission of the accuracy and relative completeness of the reports.

In Great Britain the recorded prevalence as indicated by clinic admissions is now one-half of that recorded in 1920. In 1920, 42,805 cases were admitted to treatment centers for the first time. In 1934 the total was 20,692. In contrast, the prevalence of gonorrhea continues high and has not declined proportionately.

The essential forms of the Scandinavian plan may be summarized:

- 1 Free and universally available diagnostic and treatment services of high quality.
- 2 Adequate hospital facilities for infectious cases.
- 3 Compulsory treatment for uncooperative cases.
- 4 Thorough epidemiologic work.
- 5 Confidential relationships absolutely maintained.

In Great Britain the plans for combating syphilis and gonorrhea provide for:

- 1 Free and universally available diagnostic and treatment facilities of high quality.
- 2 Complete protection of confidential relationships.

There is in Great Britain no provision for compulsory treatment, no reporting of cases, and little or no epidemiologic work.

It is generally agreed that the splendid results obtained in the Scandinavian countries and Great Britain are due mainly to the provision of treatment

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 26, 1937*

SYPHILIS AND GONORRHEA

Number 211

facilities, and that the spectacular reduction in the prevalence of syphilis has been achieved by the simple process of rendering infectious cases noninfectious.

At my request, in 1935, the American Social Hygiene Association made a survey of New York City to learn, as far as possible, the size and nature of the venereal disease problem, the facilities then existing in the city for dealing with this problem, and to outline a program for combating syphilis and gonorrhea under the conditions known to exist. Among the important findings of the American Social Hygiene Association in this study were the following:

The prevalence of syphilis in New York City was estimated at approximately five per cent of the whole population. There are probably twice as many cases of gonorrhea in New York City. Based on the size of the city and the need for diagnostic consultation, treatment, epidemiological and educational activities, it was estimated that at least \$500,000 per year should be available for combating syphilis and gonorrhea, as compared with \$131,000 which was available in 1934. The experts of the Social Hygiene Association strongly recommended the creation of a separate bureau in the Department of Health and suggested that to this bureau should be assigned all Health Department functions for dealing with syphilis and gonorrhea as public health problems, and to this bureau should be appointed a full-time medical director and adequate subordinate personnel. Finally, the report of the Social Hygiene Association recommended a program which would bring private practitioners as fully as possible into the campaign against syphilis.

Last I would mention a special committee appointed by the Academy of Medicine of New York City to consider the problems of venereal diseases, and to make such recommendations as the committee saw fit. This committee, composed of very distinguished medical men, after careful study made a recommendation of which the principal ones are as follows:

- 1 Popular education
- 2 Availability of ambulatory and bed treatment facilities, especially for infectious cases

- 3 Postgraduate instruction of physicians
- 4 Free diagnostic service.
- 5 Free drugs for physicians
- 6 Adequate reporting of cases
- 7 Case finding and case holding activities for patients of hospitals, clinics, and private physicians
- 8 Special attention to prenatal syphilis

The information and advice presented in these three studies and in certain other surveys, provided the basic facts and a program of action against syphilis and gonorrhea in New York City. In a word, this plan called for (1) widespread popular education, (2) diagnostic facilities where all could reach them, (3) treatment facilities for every infected individual, those who can pay going to private physicians, the poor or indigent being treated at public expense, (4) assistance to private physicians in caring for individuals on the economic border-line between indigency and independence, (5) follow-up for cases that have ceased treatment while still infectious, for finding sources of infection, for persuading families of infected persons to be examined, and instructing patients regarding the prevention of the spread of infection.

On October 1, 1935, I created a new bureau in the Department of Health and placed in charge of it Dr. Walter Clarke, loaned by the American Social Hygiene Association. To this bureau I assigned responsibility for the practical development of activities in this field of public health.

In the nineteen months since starting this bureau, I am able to say that substantial progress has been made. Principles of action have been established, personnel have been assembled and trained, services made available throughout the city, and the cooperation of official and voluntary groups have been obtained.

In 1936 about 67,000 cases of syphilis and about 13,000 cases of gonorrhea were reported to the Department of Health. Weeding out the duplicates we find that about 40,000 of the cases of syphilis were reported for the first time, and of these 27,000 were discovered by the clinics of the Department of Health. It is believed that at least 12,000 fresh infections of syphilis occur each year in New York City, judged on the basis of the total cases coming under medical care.

The first objective of the New York City Department of Health is to aid private physicians in discovering, treating, and controlling syphilis among patients who go to private practitioners. The practical aids which the Department of Health offers may be briefly described as follows:

1 Diagnostic services. The Department of Health laboratory performs serologic tests for syphilis without charge (345,000 specimens tested during 1936). At every one of the sixteen diagnostic centers blood specimens are taken for private physicians on request. Expert darkfield examinations and diagnostic consultations are offered in these centers, the reports being sent directly to the physicians. These diagnostic aids are available for all types of syphilis, and physicians are invited to use this service freely without fear of losing their patients.

2 Treatment services. In order to enable private physicians to care for a larger number of patients having syphilis, especially that large body of individuals who cannot pay the full regular fee, the Department of Health using Social Security funds provides nearsphenamine, bismuth or mercury in amounts sufficient for one year of the treatment in accordance with modern therapeutic methods. These drugs are supplied free upon request without distinction as to the patient's ability to pay the physician a full fee or any fee for his service. This enables private physicians to give medical care to many patients who can pay only a small fee—fees comparable with those charged by many so-called "pay clinics." Because the funds for this purpose are limited, drugs are provided to private practitioners only for the treatment of early syphilis, syphilis in pregnancy, and congenital syphilis. Later it is hoped that the same assistance may be extended to all cases of syphilis found under private medical care. Physicians willing to cooperate with the Department of Health in the diagnosis and treatment of syphilis are asked to report their cases at the time of requesting drugs, if they have not already done so, and supplies are furnished in four allotments—each sufficient for three months of continuous modern treatment. Physicians are utilizing the drugs provided by the Department of Health, and about 180 private physicians per month apply for 2,500 doses of arsphenamine and bismuth for the treatment of private cases.

Upon request, the services of especially selected and trained nurses are available to follow-up lapsed cases reported by physicians, the nurse for the time being work-

ing under the direction of the physician reporting the lapsed case. This is an important feature of the plan, since by sufficiently sustained treatment, syphilis may be rendered permanently noninfectious, and in many cases a clinical cure may be achieved.

3 Epidemiological service. In early syphilis, syphilis in pregnancy, and congenital syphilis, we have our best opportunity for epidemiologic work and many physicians in their daily practice are doing excellent case-finding work with patients of these types. The Department of Health offers its services to aid the physician in finding the source of infection of the patient having early syphilis, syphilis complicating pregnancy or congenital syphilis. For this service a group of specially trained physicians are employed. The Department makes their services available to any physician who wishes the cooperation of the epidemiologist in finding sources of infection and in bringing them under treatment, but in no cases will action be taken without the approval of the physician with whom we are cooperating. Where this plan has been in operation, about twenty-five per cent of the sources of infection have been brought under medical care, through the cooperation of the private physician and the epidemiologist.

4 Educational activities. The New York City Sanitary Code requires that every person found by a physician to have syphilis or gonorrhea shall be given a pamphlet of instruction with regard to his infection and the protection of contacts. The Department of Health furnishes this pamphlet to physicians and clinics. New editions in appropriate foreign languages have been prepared. The Department also cooperates in making postgraduate instruction available to physicians, bringing to their attention the most accepted modern ideas and methods of diagnosis and treatment of syphilis. During April 1937, for example, thirty-six lectures were given to lay and professional audiences, and our motion pictures, stereopticon slides were shown sixteen times. Hundreds of thousands of pamphlets are distributed, and our exhibits are shown to tens of thousands of seekers after information.

5 The Reporting of syphilis. In reporting a case of syphilis or gonorrhea or other communicable diseases to the Department of Health, a physician renders a valuable public service. The least that the Department of Health can do, it seems to me, is to make reporting convenient and free even of the cost of postage. A plan to that effect has been placed in operation in New York City. Reporting by initials and ad-

dress is permissible but not encouraged and I wish to emphasize that all reports are strictly confidential, and are kept under lock at the Department of Health

The forty-eight clinics of voluntary hospitals in New York City should play a more important part in the fight against syphilis. Many of these clinics would be willing and able to provide treatment without charge for a larger number of poverty stricken patients if drugs were supplied by the Department of Health. To clinics which charge only low fees—fees that cannot possibly compete with those of private physicians, the Department of Health now provides drugs to enable them to care for indigent luetic patients. During the month of April twelve hospitals received drugs for the free treatment of 540 patients. The total number of doses provided to these hospitals was 2680. In this manner, facilities are increased and brought closer to those who need them.

The Sanitary Code regulates the conduct of these clinics and requires the maintenance of certain standards including adequate personnel for the follow-up of cases. After clinics have exhausted their resources in endeavoring to return lapsed infectious cases to treatment or to bring sources of infection under control, the Department of Health now employs its legal authority to seek out such uncooperative individuals and bring them under medical care. This interesting and permanent feature of the work of the Bureau of Social Hygiene has received emphasis during the past year, thus in the first quarter of 1936, 114 lapsed cases, sources of infection, and other individuals requiring follow-up were referred to the Bureau by the hospitals, clinics, and private physicians. In the first quarter of 1937, the total number of individuals referred to the Bureau from the same sources was 3406, an increase of almost 2980% over the corresponding period last year. These cases are given very special attention by the social workers, nurses, and physicians of the Bureau of Social Hygiene.

The provision of treatment for syphilis in indigents and others who cannot pay, whether this treatment be ambulatory or inpatient, is primarily the function of the various tax supported hospitals of the

city. In spite of the best efforts of the Department of Hospitals and although progress has been made in 1936, the facilities are still very far short of the needs of the city, especially in respect to bed accommodations. The greatest single need in New York City, it is believed, is more bed accommodations for infectious cases of syphilis and gonorrhea whether they be voluntary admissions or legal removals by the order of the Health Department. In the New York City fight against syphilis, scarcely any more important development has occurred than the provision of funds for the payment of physicians rendering medical services in the syphilis and gonorrhea clinics of the city's hospitals. This will result, it is believed, in much more and much better service for the infected poor.

The relation of the health authority to the City Hospital clinics is defined by the provisions of the state law and of the Sanitary Code. They provide for the follow-up by the Department of Health of lapsed infectious cases and sources of infection and give the Department power to require examination and treatment if indicated. Certain City hospitals receive and give medical care to infectious cases of syphilis and gonorrhea removed to them by the authority of the Health Department. Neither the private physician nor the hospital whether voluntary or official has the authority to detain forcibly a case of infectious syphilis or gonorrhea. But by bringing such a case to the attention of the Department of Health appropriate action can be and is promptly taken for the full protection of the public health, and such cases are received by a city hospital designated by the Board of Health. More use should be made of this authority vested in the Department of Health, but more bed accommodations are needed before the laws can be used to the fullest extent for these quarantine procedures.

The Department of Health has primarily the duty of promoting, directing, and aiding the attack on syphilis as a communicable disease. As a matter of sound policy it may work through other agencies both official and voluntary to gain its ends. It must supply deficiencies. Thus for the present it is obliged to supply a part of the treatment facilities for

the very poor and it now maintains ten treatment centers, all of which are crowded to capacity with the unemployed and other very poor infected persons. Still more treatment facilities are badly needed, though it is hoped that the larger participation of private physicians, voluntary hospitals, and the increased service of the Department of Hospitals will partly meet this need. When the Department of Health can properly close its treatment clinics, it will do so, believing that treatment of poor patients can eventually best be administered by hospitals.

A few figures are necessary in order to indicate the growth of our control activities and the reaction of the public to our efforts. In 1933 the Health Department was spending about \$119,000 for all its work in combating syphilis and gonorrhea. This was limited to the operation of several clinics. In 1937 our city budget provides \$275,000 for combating syphilis and gonorrhea. In addition, we have for 1937, about \$70,000 Social Security Act money and about \$204,000 in personnel and supplies allocated by the WPA. About \$12,000 is available from private funds. This total of over \$500,-

000 is being expended on a well-rounded, complete plan of attack on syphilis and gonorrhea. In 1933 we administered 122,000 treatments in seven centers. In 1936 treatment numbered 328,000 in sixteen centers. Comparing the first quarter of 1937 with the first quarter of 1935, that is, before the bureau was organized, we find that in the first quarter of 1937, eighty-two per cent more persons were examined, forty-seven per cent more persons were treated for syphilis, 321 per cent more patients were treated for gonorrhea, and 126 per cent more visits were made for treatment. The personnel assigned to this work, including doctors, nurses, social workers, and others increased from eighty-six in 1935 to 289 at the present time.

The response of the public to our efforts in New York City has been most encouraging. This feature of the Health Department's program has been thoroughly presented to the public and has received enthusiastic public support. The medical profession has cooperated willingly and has undoubtedly shared the benefits of the program.

125 WORTH ST

FRANCE'S 'SECRETARY OF LEISURE'

We have a Secretary of Labor, why not a Secretary of Leisure? In France the 40-hour week law has given the worker an extra day of rest and recreation, so the government has created an Assistant Secretary of Sports and Leisure. We are told by the Paris correspondent of the *Journal of the AMA* that the first occupant of this office is an energetic young man, Mr. Leo Lagrange, who has announced his program in one of the Paris evening journals, the *Soir*. He stated that it was his ambition to do all in his power to encourage the creation of a strong, healthy and happy people by having them spend two days a week in the open air. A branch of the central bureau will be formed in each of the eighty-six departments of France to encourage the development of physical education. Mountain climbing and skiing enthusiasts will find shelters in every one of their favorite regions. A large park for all kinds of sports is being planned now, within an hour's ride from Paris, at Montlhéry. Similar recreation parks will be created

within a radius of thirty miles from Paris in all of the metropolitan areas. The problem of building special paths for cyclists, as now exist in Belgium, will not be an easy one in France, where there are more than ten million people who prefer bicycle riding to any other form of outdoor exercise. Mr. Lagrange is also thinking of the season when inclement weather interferes with all outdoor sports except skating and sking. He is planning to encourage workers to utilize their extra day of leisure (Saturday or Monday) to visit the museums or the cinemas and to plan to take their annual vacations (with full pay) in winter instead of in summer. Special excursion rates will be arranged so that the worker will benefit by visiting other parts of France and also foreign countries. More than 500,000 persons engaged in sking and other mountain sports during the past winter. The program to encourage the intellectual and physical condition of the workers is an ambitious one and it will be interesting to watch such a policy

PNEUMONIA

From the Standpoint of Preventive Medicine

JOHN H. MEHRLING, M D, *Brooklyn*

The pneumonias should be considered as a closely related group of acute, constitutional diseases, all having in common as a local manifestation, an acute, inflammatory process in the lungs, although the pathogenic causative factors may be multiple.

Pneumonia is an endemic disease practically everywhere in the world, people in temperate and tropical climates suffering at all times from it, although not in all countries to the same degree. The virulence of the endemic pneumonia is not the same in all countries, nor in all parts of the same country. It varies from year to year. Pneumonia is a seasonal disease and the morbidity increases in the cold or wet seasons. It has also been found that it is more common and claims about a fifty per cent higher mortality in urban than in rural sections. Hippocrates is credited with pointing out the experience that cold northerly winds seemed to be a cause of disorders of the chest.²

The contagiousness of pneumonia was noted as early as 1497 by Savonarola, and in 1592 an English physician, Dunns, commented on the fact that he observed that it attacked many members in the same family.

Records of epidemics of pneumonia have been handed down from ancient times, being mentioned as early as 1613 by Ravicio. In our own country many epidemics of pneumonia are recorded. Perhaps the earliest of these was one in Waterbury, Conn., in 1712 followed in 1719-20 by another in Hartford, Conn. Pneumonia ranked high as a cause of morbidity during the World War afflicting some 13,393 soldiers in the American cantonments during the winter of 1917-18. It carried with it a mortality of twenty-three per cent.

In the United States pneumonia has ranked chief among the infectious diseases as a cause of death for many years. From a public health point of view it makes no difference whether the pneu-

monia be due to pneumococcus, streptococcus or any other pathogenic micro-organism, for in all cases the organisms are continually thrown out by the patient chiefly by cough, sneezing, and expectoration. When they reach the body of any well person, either by direct or indirect contact they are potentially capable of and frequently do cause that individual to develop pneumonia. Pneumonia should, therefore, be considered a communicable disease and classified with the infectious fevers.

Despite the gaps that may exist in our knowledge of the environmental, personal, and climatic factors in pneumonia, the data on hand warrant one definite step in the control of this group of diseases— isolation of the patient and a modified quarantine of the premises. While quarantine alone cannot be expected to eradicate pneumonia (any more than it can any of the other infectious diseases) it is of great value in decreasing the spread of the disease by contact infection. This measure would have a secondary effect of great benefit in arousing the interest of the general public and of the medical profession regarding the subject of pneumonia prevention. Finally it would encourage earnest, scientific research into the unknown factors of the problem. It is only when a given community knows the number, time, and place of its pneumonia cases that it is likely to be in a proper position to study the subject advantageously. Unless pneumonia is both reportable and quarantinable in that community, it is not likely to have such necessary information.

This proposal is not just a theoretical consideration. It has been worked out satisfactorily in Pittsburgh, Pa. The regulation covering reports of cases of pneumonia was made to include all forms (to avoid any loophole for failure to report any case). Actual quarantine in certain types of cases was made optional with the Department of Public Health.

From the Department of Internal Medicine, Long Island College Hospital

The quarantine regulations were made very moderate. It consists of placarding, isolation of the patient, prohibition of all visitors, but no restriction on other members of the household. Complete sanitary cleaning of the premises is added, as an appended regulation, before release is granted.

This plan has met with the enthusiastic support of the general public, medical profession, and hospitals of the city of Pittsburgh. It has yielded substantial reductions in the pneumonia death rate, a reduction of 245 in the number of deaths from pneumonia being recorded the first year the plan was in operation.

The problem of pneumonia resolves itself into two phases: (a) the medical aspect and (b) the engineering problem. In regard to some of the medical problems in pneumonia, such variables as exposure, excesses, fatigue, overwork, and lowered bodily resistance have been mentioned as playing an etiological role in this disease. Just what the mechanism is and how it can be counteracted constitute pertinent parts of the medical problem. From the engineering standpoint we may mention such conditions as bad housing, badly ventilated and crowded rooms, overheated living quarters with improper humidity as factors in the production of pneumonia.

It will be noted if one studies the past personal history of many pneumonia patients that a large percentage will reveal a history of a preceding common cold, "flu" or grip just prior to the onset of the pneumonia. Furthermore, climate ranks high in the contributing causes to respiratory diseases. It is not so much the general mean temperature or moisture rate but the relatively quick changes in the temperature that matter. Alternating cold rains and sunshine, snow and sleet, dry cold quickly changing to moderate temperature with slushy, wet streets are widely considered as predisposing factors in the production of common colds and thus secondarily of pneumonia.

There are many unsuspected factors that enter into the spread of pneumonia. These can only be hinted at. They include exclusion of beneficial bactericidal sun-rays through fogs, smoke, air pollution, climatic data, etc. Another factor

of great importance too easily overlooked is the common practice of handshaking. This was considered a sign of security centuries ago, proving there was no weapon concealed; today the extension of the right hand frequently spells sickness and death through a mutual exchange of saliva with its ever-present luxuriant flora of pathogenic bacteria. It has been well said "if saliva were colored blue, we would all have blue fingers continuously."

Statistical study of lobar pneumonia morbidity has proven unsatisfactory chiefly because the report of morbidity required the attending physician to sign his name to a statement regarding the positive differential diagnosis of the case as between lobar and bronchopneumonia, a diagnosis that is often difficult to establish. This encouraged delay awaiting developments and all too frequently failure to report the case morbidity at all. Likewise pneumonia mortality statistics are unreliable, many deaths being charged to this disease that were basically due to other syndromes.

The most satisfactory advance in our knowledge of lobar pneumonia has come in recent years with the discovery of type specificity of the pneumococci.⁴ While all pneumococci appear similar under the microscope, it has been discovered that they differ antigenically. Of chief importance in the line of type specific components are the glycoside (a complex carbohydrate) and the nucleoprotein of their capsule. At present there are some thirty-two verified specific types of pneumococci. The importance of this discovery is not merely in its academic implications, but of even greater importance is its thoroughly practical application in epidemiological diagnostic and therapeutic procedures. These type specific components are dissociated from their normal residence in the capsule of the pneumococci and are found in the serum and body secretions of the patient and the infected animal. Furthermore, since the nucleoprotein is specifically antigenic, it is productive of specific antisera in experimentally inoculated animals. This led to the work of Avery, Cole, and Dochez in which they first produced effective horse antiserum for Type I pneumonia. In order to be effective, huge

doses of this serum (80-90 c.c.) were given intravenously by the gravity method. In time modifications followed, chief among which was the development of a refined antiserum by Felton. Experimental work had shown that the specific pneumococcus antibodies were to be found in the euglobulin fraction of the horse antiserum. Felton therefore set about to eliminate the large portion of ineffective horse serum which did much to encourage or intensify allergic reactions but little, if anything to abate the pneumonia, or precipitate a crisis. By a simple method of precipitating the euglobin fraction in one-third saturation of $(\text{NH}_4)_2\text{SO}_4$ he had concentrated the effective fraction into a small volume indeed. This is then resuspended and standardized in units (rather than by volume). A unit has been defined as the least amount of serum which will protect a standard white mouse against 1,000,000 lethal doses of pneumococci.

However, this is but one phase of the story. A type specific antiserum is of little or no value unless the specific type of invading pneumococcus for a given patient can be determined. Furthermore clinical results show that success in the treatment of pneumococcic pneumonias with specific antisera is dependent to a large degree on the early administration of the serum. This postulates a reliable method of rapid identification of the infecting organism. Several methods have been used with reliable results but always the element of time has tremendously detracted from their practicability. Chief among these was the mouse typing in which the peritoneal cavity of a white mouse was used as a differential culture medium. The mouse has so little resistance to the pneumococcus, that although it is planted with many contaminants in its peritoneal cavity, after eight to twelve hours a practically pure culture of pneumococci can be obtained. Agglutination tests are then done on suspensions of this pneumococcus and the results reported. The factor of time is indeed a great obstacle to the use of this method.

Of late a much more simplified and just as reliable a method has come to enjoy widespread usage.¹ The method is not new, having been described by Neu-

feld in 1902. In his original article he reported that the capsules of pneumococci in contact with specific antiserum became swollen (hence the descriptive title *Quellung* phenomenon) and more distinctly outlined, the capsule itself taking on a ground glass appearance. In 1931 he added that he had found specific rabbit antiserum to be much more potent (antigenically) and productive of a more definite reaction than the usual horse antiserum. In 1932 Armstrong et al. reported that the reaction could be applied practically to the determination of the type of pneumococcus directly in sputum. In testing the reliability of this procedure as a diagnostic method, Sabin in 1933 applied it to one hundred cases of lobar pneumonia, using rabbit antisera. With Type I and Type II antisera he was able to identify one or the other of these types in fifty-three cases and obtained no reaction in forty-seven, which were subsequently shown to be caused by other types.

As was noted above some thirty-two authenticated specific types of pneumococcus have been identified (and an equal number are now in the process of identification). This presents a real practical problem for the laboratory diagnostician which has been met in a simple yet ingenious way. The sputum is first mixed with a drop of each of three polyvalent antisera (containing ten or twelve specific types each). If the *Quellung* phenomenon is observed in Drop A, the sputum is subsequently mixed with a drop of each of two polyvalent antisera containing six antisera which were also present in A. If now a reaction occurs with Drop E the sputum is tested with a drop of each of its component sera. Chart I simplifies this wordy explanation. The use of this rapid method of typing gave rise to another difficulty. In using the polyvalent antisera it was occasionally found that a positive reaction could not be elicited. This was attributed to the relatively large amount of soluble specific substance in sputa loaded with pneumococci as these specimens were. It was subsequently found that while working with a monovalent antiserum a combination of four parts antiserum to one part sputum is usually adequate, a relatively greater amount, about in the proportion of the

Fig 1 (A) Positive Neufeld reaction (B) Negative Neufeld reaction

antisera combined, i.e., twenty to forty times as much serum to sputum was necessary to give reliable results

An illustration of positive and negative Neufeld reactions might be in order (Fig 1).

The Neufeld method of typing pneumococci seems to be the most rapid and reliable that has yet been devised. It has the advantage that it can be applied wherever suitable microscopic means are available without other more cumbersome laboratory material. It has the further advantage that the approximate number of pneumococci present can be estimated, and if more than one type is present, one can see which is the predominating (and offending) one. Further it eliminates the chance taken by mouse typing that certain mouth pneumococci (though small in numbers in the sputum) may be more virulent for the mouse and overgrow the type productive of the patient's infection.

The relation of pneumococcus typing and the development of type specific antisera to public health is close indeed. While we cannot at present hope to stamp out pneumonia by sanitary engineering (as was done with typhoid) or by mass immunization (as is being done with diphtheria), our present knowledge should encourage us to attempt to decrease the mortality that this disease exacts each year by prompt and adequate treatment of such cases as are amenable to specific serum therapy. Notwithstanding the advances made by Cole at the Rockefeller Hospital in the serum treatment of type I pneumonias and later the refined, standardized serum used by Felton, serum therapy was still restricted to the large hospitals until 1930. With the idea in mind of evaluating serum therapy, the

Massachusetts Department of Public Health obtained financial assistance from the Commonwealth Fund of New York City to operate a plan of state-wide distribution for antiserum. The essential features of this plan and its attainments follow:

1. A state-wide system of laboratories was instituted for rapid typing of all cases. This is a preliminary to the administration of the proper serum.

2. The efficacy of this specific serum therapy is directly correlated with the stage of the disease during which it is administered. Very early treatment improves the results of serum therapy tremendously. With this idea in mind, this plan provided for serum available for use at home as well as in hospitals.

3. The serum, in order to prove effective, must be administered intravenously. Consultants were therefore made available to introduce this new form of therapy, as must always be the case in such a situation.

4. Widespread information and educational talks about serum treatment were instituted, in the form of articles in periodicals, speeches at medical society meetings, and graduate courses.

5. In order to put some limit on the costs of serum therapy, a table has been drawn up indicating the amount of serum preferable for each case on the basis of age, duration and extent of the disease, and the presence of complications in such a way that sufficient but not excessive amounts of serum may be issued for each patient. In order that exceptional cases may not be unduly handicapped by such limitations, more serum may be obtained upon presentation of the case before a duly constituted board in charge of serum distribution.

6. Records of the use of serum must be kept for each case and sent to the Health Department for study and tabulation of data regarding the efficacy and safety of the serums distributed. From these data, conclusions may be drawn as to the adequacy of present day dosage.

During the years 1931-35 some 743 patients were treated with serum in Massachusetts hospitals and some 213 at home, a total of 956 patients. From this study the following conclusions were drawn:

1. An average case of *Pneumococcus* type I pneumonia requires 75,000 U.

2. An average case of *Pneumococcus* type II pneumonia requires 135,000 U.

Cost. For type I the average amount

of serum would amount to \$45 while for type II the average amount of serum would amount to \$80. However, if the serum is supplied under governmental auspices it may be materially less expensive. If one takes into account the fact that pneumonia is a disease attacking young adults and those in the prime of life, in the period of their greatest usefulness, the cost does not seem excessive.

Estimated mortality reductions as a result of serum therapy follow

Mortality without serum		With serum
Type I	25%	10%
Type II	40%	25%
Type V	25%	{ too few treated to be accurate
Type VII		
Type VIII		

Such results are indeed promising and indicate that antipneumococcus serum has an established place (until a better method of treatment, or perhaps prevention becomes available) in the therapy of pneumonia cases.

Since Types I and II constitute about sixty per cent of the entire group of pneumonias, they deserve special study. It has been found that these types especially are usually spread by direct transfer of the infective agent from the patient to the noninfected. Methods to prevent such spread should therefore be taken. This may be accomplished by early diagnosis, isolation of all patients, and careful disposition of all excreta.

While the outlook for artificial immunization is by no means hopeless, it is still in the experimental phase and these experiments have frequently been complicated by extraneous factors. Therefore the chief reliance in the field of preven-

tion must be placed upon proper isolation of the patient.

With regard to reducing mortality figures for pneumonia, nothing can adequately replace specific antiserum therapy, especially in Type I. Oxygen inhalation and symptomatic treatment are also valuable, but should supplement, not displace, antiserum therapy. Every Type I pneumonia patient should be given type specific antiserum as early as possible and in large amounts. Exceptions are made by not giving serum to children who are not very ill, since most children with lobar pneumonia recover, in patients who are moribund and will probably die before serum can be administered or shortly after, and in those patients who are obviously in the stage of recovery when seen. All other cases should be treated as soon as the diagnosis is made.

The incidence of serum disease and its severity when it does exist have been reduced by the use of fifteen to thirty cc of concentrated (Felton) antiserum in place of the huge doses of straight, poorly standardized serum. In order to guard against any violent reactions in using serum, preliminary tests for serum sensitivity may be made, injections made slowly, and adrenalin used promptly in case any symptoms occur.

The efficacy of Type II has not yet been fully established. Its use, however, in Type II pneumonia is clearly justified especially when the very best serum is obtainable. It does not seem advisable at present to use Type III antiserum. With regards to the other types, some degree of success has been obtained, but experience with them has been too limited to

CHART I—DIAGNOSIS TYPE VII PNEUMONIA

draw conclusions. Of especial use in this larger group are Types V, VII, VIII, and XIV antisera.

Perhaps the most recent trends in the development of an intelligent public health viewpoint with regard to pneumonia are the following:

1 The U. S. Government mortality statistics for 1935 have just recently been published in their complete form.⁵ Among other valuable contributions, they point out that pneumonia mortalities have increased progressively from approximately 83,000 in 1933 to over 100,000 in 1935. Pneumonia still holds first place among the infectious diseases as a cause of death in the U. S. in the vital statistics of the Census Bureau.¹

2 New York State⁶ has taken legislative action to provide for an ample supply of pneumococcus antiserum. This bill was passed unanimously by both houses of the legislature, indicating that at last intelligent public opinion has been brought to bear upon this subject in an attempt to stem its ravaging tide. The bill provides for an appropriation of some \$400,000 to bring the "latest approved methods of medical science to bear in the most comprehensive attack yet launched anywhere against pneumonia." In the words of one of its proponents: "No health measure in the history of this or any other legislature has been so momentous in the direct saving of thousands of lives."

A more fitting finale to an article on "Pneumonia—From the Standpoint of Preventive Medicine" could hardly be found than these two excerpts from current events. They indicate more definitely than much theorizing the recognized importance of pneumonia as a public health problem. It is to this problem that the practicing physician as well as the

delegated public health officer will have to apply himself if progress in the control of pneumonia is to be made.

Summary

In order to further interest in decreasing the mortality rate from pneumonia, active steps should be taken by public health authorities and should consist in:

1. Providing laboratory aid for proper and early diagnosis of all cases.

2. Arrangements for proper registration of all cases for epidemiologic studies.

3. Educational measures for providing proper isolation of patients.

4. Supplying serum that is of maximum strength.

5. Assisting in the prompt and proper administration of the serum.

The institution of efforts by public health authorities will spread information concerning the epidemiology of the disease and stimulate investigation into the details of the infective process and the nature of immunity. Under such conditions, with the public cooperating, the time should not be too far distant when pneumonia will be as infrequent a cause of mortality as typhoid is now.

DOCTORS BACK A DOCTOR FOR OFFICE

The candidacy of Dr. Charles N. Gelber, president of the Physicians and Allied Professions Nonpartisan League, who is a candidate for Councilman from Manhattan on the Fusion and Progressive parties' tickets, has been endorsed by four medical bodies; it was announced at a luncheon of the league in the Murray Hill Hotel.

Copies of resolutions approved by the groups, which include the Medical Society of the County of New York, were read at the luncheon by Dr. Morris Rosenbaum, who pointed out that this was the first time

the society, which was organized in 1806, had endorsed a candidate for public office. The other organizations approving Dr. Gelber are the Audubon Medical Society, the Physicians Equity Association of America and the Medical Alliance.

Dr. William H. Park, director emeritus of the Bureau of Laboratories of the Health Department, praised Dr. Gelber as a medical man and urged that he be supported.

Dr. Park was elected honorary president of the league. He is the first person to hold that office.

ACCIDENTAL SMALLPOX VACCINATION AND ECZEMA VACCINATUM

GAYLORD W GRAVES, M D and CORDELIA DOWMAN, M D, *New York City*
From the Department of Pediatrics, New York University College of Medicine and the
Children's Medical Service of the Third (New York University) Medical Division,
Bellevue Hospital

There is a notable paucity in the American literature of case reports of generalized vaccinia. Doubtless many more cases occur than are reported or perhaps recognized. Since numerous reviews of the foreign literature on this subject have been published, a complete summary will not be attempted. Ellis¹ and Tedder² in their reports include references in considerable detail to contributions by previous writers.

In 1904, Professor F Blochmann, a noted zoologist of Tübingen, published a work raising the question whether vaccination was surrounded with adequate safeguards. Blochmann (although himself not primarily engaged with medicine) was sufficiently broadminded to appreciate, when his own son had lost an eye as the result of accidental vaccination, that the problem involved did not relate to the wisdom of vaccinating, but rather to the question of sufficient care in vaccinating. In his research, covering the period from 1880 to 1903, he found that in 140 cases of vaccinal infection, infectious material was conveyed by recently vaccinated children. In sixty-one cases the eyes were seriously involved, with severe disturbance or actual loss of vision in nine. In sixty-five cases, mothers were affected, and unvaccinated children in twenty. In nineteen cases of this group of children in which eczema was present, vaccinia became widespread and death resulted in five. In one case ulcerative keratitis occurred, ending fatally. An excellent report by Dock³ cites in detail the review made by Blochmann and the tragic case in Blochmann's own child which is recorded as follows:

The boy was born January 6, 1901. From the 3rd month he had slight eczema which remained chronic on the face. On November 3rd or 4th (following the vac-

cination of an older brother October 21st), the eczematous infant became ill, and from the 10th or 12th of November (or about 20 days after the elder child's vaccination), he developed pustules on the face, hands, thighs, and abdomen. On November 13th, the face was scratched and bled freely. The following day the right eye became involved. Perforation and panophthalmitis rapidly followed. Recovery was slow and unsightly scars were left on the face.

A woman who washed the child's bandages acquired typical vaccinal pustules on her wrist.

Marick⁴ emphasized the fact that generalized vaccinia is divided into two groups: one developing on an underlying skin lesion such as eczema, impetigo, or abrasions, as the result of direct or indirect contact, the other known as "true vaccinia", developing as a result of conveyance by cowpox infection through the blood stream about nine to eleven days after vaccination. Marick reported a case of "true vaccinia" (associated as are most such cases with a strong "take" but running a mild course) in which, after the eleventh day, crops of lesions going through the stages of a vaccination lesion, kept appearing for over three weeks.

Platau,⁵ in an article entitled "Eczema Vaccinatum," published in 1934, noted that although vaccinia from autoinoculation tends to be benign, even in the generalized form, the same disease superimposed on infantile eczema is far more serious, and usually fatal when the face is involved. He emphasized this fact by a very thorough case report which is here abstracted in brief.

A white boy, aged five months, was admitted to the hospital for fever, restlessness, and facial eczema. For two days this had become aggravated by pustulation and swelling. During the next three days the lesions spread over the entire face. The

Read at the Annual Meeting of the Medical Society of the State of New York
Rochester, May 26, 1937

temperature became elevated to 104. Confluent grayish white pustules with indurated borders and central depressions developed. Inquiry then revealed that a three-year-old brother of the patient had been vaccinated two weeks prior to the onset of the present illness. Stupor, slight strabismus, dyspnea, hyperpyrexia, abdominal distension and signs of pneumonia completed the clinical picture. The child died about the fourteenth day, shortly after the pneumonia became apparent. Postmortem cultures from the skin, spinal fluid and blood were sterile. However, autopsy culture of the brain tissue yielded a streptococcus, and glycerolated brain tissue injected intracranially into rabbits produced death in twenty-four to forty-eight hours. A positive identification of the etiologic agent was inconclusive, although it was thought that the virus of smallpox might have been present.

Platau concluded that vaccinated areas in children should be dressed and that extreme caution should be observed in vaccinating infants with open skin lesions.

Ellis⁴ (1935) reported two cases occurring in twin boys, three years of age, in which the diagnosis of eczema vaccinatum was made. In one, which terminated fatally, pustules developed about twelve days after the vaccination of an elder brother. From an extensive review, Ellis concluded that few cases of generalized eruption due directly to the vaccine virus are to be found in the American literature, that there is substantial evidence that eczema vaccinatum and generalized vaccinia are essentially the same, and that in both diseases the virus is disseminated by the blood stream. He commented that in eczema vaccinatum the appearance of the lesion mostly or only on eczematous areas does not prove that the virus arrives there by experimental autoinoculation, as it may be prone to develop in an area of lowered resistance following blood stream dissemination. By the same authority, the work of Gins and his co-workers⁵ was cited in support of the view that the virus is disseminated by the blood stream following vaccination.

Lillie and Armstrong⁷ in concluding an exhaustive report on the pathology of generalized vaccinia in rabbits, published in 1930, state

The primary effect of the virus of vac-

cinia and variola appears to be cell irritation and injury, manifested by proliferation, various forms of cell degeneration and coagulation necrosis. The inflammatory reaction is much less conspicuous in the parenchymatous visceral lesions than in those of covering epithelia. It appears to have been primarily mononuclear and proliferative in nature except where necrosis or secondary bacterial invasion have occurred. The cutaneous, mucous membrane, and visceral lesions of variola and vaccinia parallel each other so closely as to lead inevitably to the conclusion on purely pathologic grounds that they are the effect of one virus, which, it is true, shows varying degrees of virulence.

Very recently the subject, "Eczema Vaccinatum" has been exhaustively reviewed by Tedder². He emphasizes the identity in clinical appearance of eruptions thus designated and the varicelliform and pustular vacciniiform conditions described by Kaposi in 1887 and Juliusberg in 1898. Failure to obtain a history of exposure to vaccine virus, according to Tedder, accounts for the failure to use a single term of designation for numerous cases variously labeled but clinically in the same category.

Inoculation of the contents of lesions into a cornea of a rabbit is indicated in doubtful cases to establish the virus etiology.

This authority furthermore interprets true generalized vaccinia as a disturbance of balance between the virus and the viricidal substances in intact healthy skin, so that the virus, which is disseminated hematogenously following its inoculation, becomes active in the skin and produces the characteristic vesicopustular eruption. He considers eczema vaccinatum, as due in most instances to exogenous inoculation.

Basis for further consideration of the problem is afforded by the following case records from the Children's Medical Service of Bellevue Hospital.

(The photograph of the colored child whose case is first to be described is presented through the courtesy of Dr. Howard Fox. The other photographs and charts were made by Dr. Charles H. Smith.)

Case Reports

CASE 1 A colored boy aged two and one-half years, was admitted to the Chil-

Fig 1

dren's Medical Service of Bellevue Hospital on October 6, 1929. The patient had had eczema for one and a half years which was generalized and scaly. Three days before admission the patient became feverish and listless and the rash on the neck became pustular. On admission, the child was acutely ill. The face and hands were covered with small papules about one-half cm in diameter, which felt hard and shotty. The neck was swollen and covered with umbilicated pustules with an indurated margin (Fig 1). The cervical and axillary glands were enlarged and tender. Over the arms, legs, and trunk were dry, scaly lesions, some of which were papular. The eyelids were swollen. The conjunctivae, however, were clear.

On September 16, a three-year-old sister had been vaccinated. Eight days later the vaccination was declared a "take" and the scab separated on October 4.

During the patient's stay in the hospital, the temperature remained around 104-105° for twelve days. The general condition became rapidly worse and the patient expired on October 18. A necropsy showed eczema and vaccinia of the skin, fatty degeneration of the liver, cloudy swelling of the kidneys, congestion at both bases of the lungs, and congestion but no evidence of encephalitis in the brain.

CASE 2 A white male child one year of age had been well until the age of nine months when solid food had been added to his diet. Eczema of the face, trunk, legs, and arms developed two to three weeks later. This was scaly but never oozing.

On February 21, about eighteen days prior to our first observation, the patient's two-year-old brother was vaccinated and at

the same time the patient was given diphtheria toxoid. The brother's vaccination took well with three vesicles which were never known to be scratched or broken. In fact a dressing had been put over the vaccination and long sleeves worn. On March 6, the patient's face became swollen and next day fever was noted and the left eyelid was swollen. By March 8, anorexia was marked, fever was continuous, and for the first time lesions appeared on the anterior chest, abdomen, wrists, thighs, and knees. These were described as "water blisters," some single, some grouped.

On March 10, I was requested to see the case by Dr. Vincent Malerba who himself had succeeded the physician first in attendance. No information was given relating to the vaccination of the patient's brother upon this examination but the appearance of the case was so unusual and striking that we remarked that one might justifiably think of smallpox on seeing the eruption which included discrete, shotty and umbilicated lesions difficult to associate etiologically with the eczema. The infant's parents readily consented to have the patient removed to Bellevue immediately and there on the same day the diag-

Fig 2

nosis of vaccinia complicating eczema was made and confirmed by a more complete history and the opinion of dermatologists

Upon admission March 10 with temperature 103° , the child appeared acutely ill and toxic. There was marked swelling of the face so that the eyelids could not be opened and the entire face, upper chest, lower abdomen, groins and buttocks were covered by masses of lesions which consisted of confluent lentil-sized umbilicated pustules. At the borders of each mass, where discrete lesions existed, the pustules were surrounded by an inflammatory edematous halo. In addition to these patches there were about a hundred similar lesions scattered over the entire body but predominantly on the hands and upper chest. Some of these lesions were discrete and others confluent.

The accompanying illustration secured shortly after this child's admission to Bellevue Hospital give a better idea of the skin appearance than a word description (Fig 2). During the patient's stay in the hospital his temperature ranged from $102-104^{\circ}$ without wide fluctuation. Prostration and stupor were continuous except for insignificant intervals. Signs of bronchopneumonia were detected on March 17. In spite of some subsidence of the edema of the face, death occurred March 25.

On March 12, the mother of the patient whose case has just been cited, likewise developed similar lesions, which were indurated and vesicular, on her palms and upper arms, with one lesion on the face (Fig 3). A temperature of 102° was associated with the skin condition. She recovered after two weeks. Inquiry elicited that she had not been vaccinated since the age of eight years.

Ruhrah,⁷ discussing complications due to vaccine virus, stated "When an individual is suffering with any skin disease or has numerous abrasions upon the skin and the vesicle becomes ruptured, the virus is easily transferred usually by scratching, and in some instances a very severe generalized vaccinia has been produced."

Most commonly autoinoculations occur upon the cheek, tongue, breasts, and buttocks with a tendency to affect particularly patches of eczema. The instance is recorded of a physician who vaccinated several children, and then, upon being asked to remove a foreign body from the eye of the mother, did so without first washing his hands. The

eye was saved only by continuous and careful treatment. Even ointments used on vaccination sores may transfer the virus, as noted by Ruhrah in reporting a case of a man who was inoculated accidentally as the result of applying ointment to chafed areas produced from riding horseback.

Occurrences not dissimilar are recorded by several earlier writers cited in Tedder's report.

We have been informed by a professor of pediatrics from Cologne that in Germany it is against the law to vaccinate any child in whose environment there is a case of eczema.

Fig 3

For lack of time a consideration of vaccination methods, particularly intradermal vaccination, is not included in this report.

Finally it would be regretable if this recital should be interpreted as an anti-vaccination argument except in exceptional instances. More and better vaccinations are in order.

Conclusions

1 Two cases of eczema vaccinatum are reported with autopsy findings in one.

2 It is recommended that in considering vaccination, inquiry be made into the presence of eczema or other skin diseases in the patient's family or environment. If eczema is present in the

family no member of it should be vaccinated

3 The importance of careful technic in the operation is emphasized and a suitable nonrestrictive but protective gauze dressing for the sore in its active stage is recommended

Discussion

DR. DONALD D. POSSON, *Rochester*—Several years ago a case was seen at the Strong Memorial Hospital which was similar to those reported by Dr Graves. This was a three year-old boy with eczema who had been infected with vaccinia by an older brother. The brother also had eczema and had been vaccinated about two weeks before. Our patient had vaccination pustules scattered over the entire body, was very toxic, developed bronchopneumonia, and died.

Recently Rivers and Ward have reported a method of intradermal vaccination against smallpox which produces no pustule and consequently causes no scar formation and leaves no scar. They used a culture vaccine virus which they have carried through numerous passages in chick embryo tissue and Tyrode's solution. The cultivation of vaccine virus *in vitro* has provided a bacteria free agent mild enough in its action to be injected intradermally in humans. This virus is mixed with gum acacia, frozen and dried and sealed in small glass containers. For use in intradermal vaccination the contents of one of these containers is dissolved in two c.c. of sterile saline solution and 0.1 c.c.

is injected intradermally into the skin. Care must be exercised that the needle hole be washed well with alcohol to prevent the slight leakage of solution causing a vesicle formation.

Using this method Dr Kaiser and I have vaccinated eighty-one children who had never been vaccinated before, and obtained sixty-six "takes." The height of the reaction usually occurs on the ninth or tenth day with a central dark red, slightly raised area about one cm in diameter surrounded by a secondary zone of less intense redness of two to six cm in diameter. Two cases only showed tiny vesicles. The others showed no vesicle, scar or scar. The children were not ill and could play and be bathed during the period of "take" as usual. The advantage of the lack of vesicle formation is obvious.

Although we did not use this method to vaccinate any child suffering from eczema, we believe it would be perfectly safe to vaccinate other members of a family in which a case of eczema existed and that the extended use of this method may help to prevent such fatal accidents as have been described by Dr Graves in his excellent paper.

THE DOCTOR'S WIFE IS CELEBRATED IN SONG

A delightful feature of the annual meeting of the Woman's Auxiliary to the Medical Society of New Jersey was a poem by President Herrman of the State Society, which he read at the luncheon of the Auxiliary.

When you come home as daylight dawns,
Who turns in bed, and only yawns?

The Doctor's Wife.

In broken bone or typhoid fever,
Who thinks you're tops like John B. Deaver?

The Doctor's Wife.

When accounts run low and it's your crisis,
Who lets you down by easy lysis?

The Doctor's Wife

When you're so tired you could die,
Who lifts the 'phone and tells a lie?

The Doctor's Wife

'Less some one lies and screams with pain,
Then sends you out in snow or rain?

The Doctor's Wife

If I am by you understood
Who takes care of the neighborhood?

The Doctor's Wife

A PSYCHIATRIST IN A POLICE COURT

Impressions and Experiences

RICHARD C A JAENIKE, M D, *Rochester*

Assistant Professor of Medicine and Associate in Psychiatry, School of Medicine, University of Rochester

The need for psychiatric clinics in Criminal Courts has received an increasing amount of comment since their inception a few years ago. While the subject of delinquency and crime in its protean phases has been freely discussed in the newspapers, magazines, and over the radio, much of the discussion has been based upon opinion rather than facts, with little appraisal of the results of various forms of treatment. Considering the mounting seriousness the crime problem now presents to the country, it is felt that a survey of a series of typical offenders referred by city and county courts may be of interest and value.

This paper concerns the psychiatric study of prisoners remanded by City Court Judges for examination and opinion. The clinic consists of a part-time psychiatrist who spends two half days a week at Police Court, a consulting psychologist, and the staff of the City Probation Department. The latter make all the initial investigations, submitting a detailed case history. This staff also plays an important part in the follow-up work of cases recommended for probation.

In the beginning this service was limited to the obvious psychopathic cases where the question of commitment was of primary importance. As the service and amount of time increased it has become possible to make routine examinations of a large variety of cases and more detailed studies, carrying certain cases through psychiatric outpatient clinics, planning rehabilitation programs with probation staff and local social agencies.

The method of procedure varies in individual cases. Misdemeanants are seen at police headquarters, frequently for

only one interview as it is unfair to detain the individual in jail any longer than necessary and because of delay to court routine and crowded dockets. Acute and difficult cases are sent by police commitment to hospital for observation and treatment as long as the psychiatric staff consider necessary. In the matter of felony cases, the psychiatrist may take a longer period of study, seeing the accused repeatedly or referring him to psychopathic ward if indicated.

The type of interview must be diversified as each delinquent presents a different problem. For example, The habitual criminal or the individual with the "criminal attitude" generally gives a well-rationalized story of innocence, a categorical denial, or a simple refusal to make any statement. The orthodox psychiatric approach is unproductive. With some an aggressive direct method of questioning elicits sufficient information to get a picture of the person's makeup, an attitude about himself and toward society. An explanation that his cooperation may lead to a happier solution for everyone concerned is effective with others. There remain in this group a fair percentage where the interview is confined to the immediate factors of offense and arrest. Another series who make a wholesale negation, even in the face of positive evidence, are the sexual delinquents. This reaction is understandable when one considers the bitter resentment of the community. Rapport is more easily made with the first offender, the mentally retarded, and those suffering from some form of a psychosis. In our experience it has been felt that the accused associates the psychiatrist with police, prosecutor and court, even though he is assured that a confession or any data tending toward a conviction is not wanted. Another factor that may well influence the prisoner is the anxiety over

Classification used in this study follows as closely as possible the one used by the National Committee of Mental Hygiene.

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 25, 1937

tained by the probation department reveals that the native-born or foreign-born parentage contributes more to our criminal ranks than do the native-born of native parents. This conclusion has been reached by other writers and students of criminology. Of the foreign parents in our series, forty-nine per cent were of Italian birth, fourteen per cent of Irish birth, twelve per cent of Polish birth. The records showed both a lower educational and economic status in the foreign-born than in the native-born.

Any study of crime leads eventually to a search for causative factors. Arguments have been advanced that the complexity of modern life, the passing of thousands of laws, and the increasing struggle for economic survival are the basic elements. Many hypothetical causes have been explored but no single one has been scientifically determined as the responsible agent for criminality. The country's foremost authorities in this field stress preventive measures as the best means of combating delinquency. To this end socially-minded groups have organized coordinating community programs, more widespread recreational facilities, and mental hygiene clinics. Our study shows the criminal possesses an early developmental period characterized by a marginal economic standard of living, poor home, and delinquent or semi-delinquent neighborhood, and inadequate parental controls. The habitual criminal in the great majority of instances had an early history of delinquency, undesirable habits and companions, and irregular employment. Among our adult first offenders, one notes as outstanding problems economic stress, sexual difficulties, marital incompatibilities, and dissatisfaction with their situation in life.

Our general conclusions are that factors causing antisocial behavior are extremely complex and multiple. Practically no physical findings were found that had any significant correlation with criminal or delinquent tendencies.

The city court judges realize the futility of punishment in many cases, but year after year the same group of offenders appear before them and for the lack of any other disposition the judge must of necessity order the same method of disposition realizing that the results

will probably be disappointing. This is particularly true in cases of public intoxication. The Court records of several of these cases are rather interesting, for instance, one chronic alcoholic has spent seventeen years, two months in the County penitentiary in the past twenty-one years, another has spent seven years, four months in past twenty-one years and so on, all at the cost of \$1.08 per day to the county.

As yet there is no guide for Judges regarding disposition of offenders. They are constantly seeking ways and means to find proper methods that will modify behavior and situations. In a certain number of adults we have found that they regard life in penal institutions as very desirable. However, there is some measure of success found in a large number of cases so that the Court experience may have been a healthy one.

From the angle of therapy our studies indicate that little can be accomplished with the habitual criminal, the chronic alcoholic, and the professional prostitute. The attitude and personality make-up of these types and the present facilities available militate against rehabilitation. The excellent institutions directed by the New York State Department of Mental Hygiene offer a solution for the psychotic, epileptic, and mental defective. The neurotic individuals gain little by sentence to jail and their problems are best solved by psychiatric treatment. This plan is not wholly successful as many respond very slowly to therapy. Situational depressions can very often be aided through psychotherapy, an active probation service, and the assistance of local agencies. The same technics are frequently helpful in readjusting the dullard and borderline individuals.

A Court psychiatrist quickly recognizes the dilemmas arising from the legal and medical concepts, but must endeavor to harmonize the two as much as possible if his work is to benefit either society or the delinquent. Many of the present difficulties will undoubtedly be solved with time and experience. In conclusion, we have found that criminal acts are not always committed by certain individuals who can be defined, socially, psychologically or psychiatrically.

Discussion

DR. R. MONTFORT SCHLEY, *Buffalo*—The Erie County Probation Department deals exclusively with major crimes. All cases examined in this department are before the County or Supreme Court so that I, as psychiatrist, have had little experience with criminals in the lesser courts. The criminals are examined after conviction and the psychiatrist is used not only to weed-out the mentally unbalanced and abnormal, but he is used to get the attitude toward society and the reactions to everyday life of the convicted man, and to see if he is antisocial and liable to be a danger to society—all to help the Judge in sentencing him.

One of the greatest helps that I have found in my work with criminals is the classification given by Dr. Menas S. Gregory, Head of the Psychiatric Division of the Court of General Sessions in New York (*American Journal of Psychiatry*, January 1936) and a revised classification by Dr. Thompson of the same division (*Mental Hygiene*, October 1936). Dr. Thompson classifies the criminals as definite psychosis, borderline psychosis, mental defective psychosis, personality neurosis, and normal individuals with prominent characteristics, in this last type, the majority of our criminals fall. Here we have the aggressive type, the unstable type, and the adolescent type. These are the immature boys who have not adjusted themselves to life's problems. Many of them have schizoid features and may commit crime in the spirit of adventure, who are temporarily antisocial but who soon mature and cause no further trouble. This was brought out very forcibly by Dr. Thompson a few weeks ago before the Psychiatric Association in Pittsburgh where he showed that as men grow older, as between the ages of thirty-five and forty, there are very few repeaters who come back to the Courts.

After examining many thousands of criminals during my twenty-year service in the Probation Department, I firmly believe that psychiatrists should use great care in what they offer, in regard to the cure of these criminals, to the Courts. Glueck's thorough investigation of a thousand cases from the Judge Baker Foundation, proves that eighty-five per cent were considered failures, and the results in Warwick Village in New York have been very discouraging to its founders and workers.

It is evident that the study of crimes and

criminals needs a very thorough investigation. In the Wickersham report of crime and criminals, there is a record of only 500 that had been thoroughly investigated and this was not complete as it included only one type of crime, in this report, they call attention to the lack of thorough investigation of criminals. I, too, feel that this subject has not been completely examined and that we need someone in the criminal world, comparable to Kraepelin or Meyer in Psychiatry to bring out all there is to know about criminals. I believe that all we have tried to learn about them should be discarded and a new nomenclature be built up which will lead to a better understanding of these individuals.

I firmly believe that crime is a disease of personality as truly as insanity is a disease of the mentality. I believe that the men who are in charge of our prisons should have a thorough training in crime and that they should be removed from politics. I also believe that individuals who are truly antisocial should be taken out of society and confined for the rest of their lives, for the sake of better protection of society on the same principle that our insane are kept in institutions until they die or are cured.

In the literature, we find many claims for mental deficiency being the major cause of crime. On looking over the army tests of 94,000 individuals who had careful mental tests during the World War, we find that the average is twelve to thirteen years and that 71 per cent were below this average level. In our criminals we have found practically the same proportion of mental defectives as we do in average life. My experience has been that only about one per cent are definitely psychopathic individuals. I believe that we can divide criminals into three classes: (1) The normal individual who gets into trouble through accident or because of immaturity, (2) The weak-willed individual who is easily led and influenced by others into committing crimes or who does not think things through to the ultimate end and commits crime to relieve him of immediate difficulties, (3) The definitely antisocial individual who commits crime as a livelihood. To these may be added a fourth group of the very small percentage of definitely psychopathic individuals who commit crimes on account of their insanity.

Baby ear of corn "Mama, where did I come from?"

Mama ear of corn "Hush, dear the stalk brought you"—*Jercyville (Ill.) Democrat*

ENTEROCOCCUS ENDOCARDITIS

ALFRED B CLEMENTS, M D, *New York City*

From the Department of Pathology, Bronx Hospital

Bacterial endocarditis caused by the enterococcus is extremely rare. Very little can be found in the English literature concerning its pathogenicity, most case reports being by German and French authors. Aschoff¹ was of the opinion that the role played by the enterococcus in systemic disease was just beginning to be appreciated. In view of the above, the following case is reported.

Case Report

S T a white male, age fifty, was admitted to the Bronx Hospital on the Medical Service of Dr A Goldman, May 31, 1935, with the chief complaint of fever.

His past history included pneumonia, appendectomy, and herniorrhaphy. He had never had rheumatic fever in any form, nor had he ever exhibited signs of diminution in cardiac reserve except for slight dyspnea on exertion which began about a month before onset of the present complaint.

Eleven weeks before his last admission, following an upper respiratory infection, the patient began to run a daily fever of 103-104°F. There was no chill, cough, chest pain nor expectoration, but his condition was diagnosed clinically as a pneumonia and this was corroborated roentgenographically. Two weeks later he developed hematuria. He was hospitalized in another institution where a positive blood culture of the enterococcus was obtained. Shortly after, the spleen became palpable and dark red petechiae were found in the conjunctiva. X-ray revealed a resolving pneumonia in the left lower lobe. The hemoglobin fell from seventy-five to sixty per cent. He left the hospital against advice and on his way home experienced a severe chill. A few days later he was admitted to the Bronx Hospital where several positive blood cultures of enterococci were obtained, there being about 100 to 120 colonies per c.c. of blood. The heart was found to be enlarged and of a mitral configuration. Loud systolic and diastolic murmurs were heard at the base. There was clubbing of the fingers. During the period of hospitalization, the hemoglobin fell to fifty per cent (Sahli) with 3,100,000 red cells per c.c. The leukocyte count ranged between 10,000 and 12,000 per c.c. of which eighty-five to eighty-eight per cent were

polymorphonuclear leukocytes with a marked shift to the left in the Schilling index. The temperature ranged between 101 and 104.2°F, being of an irregular, septic type. His general condition became steadily worse. Pulmonary edema developed and the patient expired in cardiovascular collapse, approximately three months after the onset of his symptoms.

Autopsy findings. The relevant autopsy findings were as follows:

Heart. The heart was enlarged downward and to the left, measuring thirteen by thirteen cm in its largest diameters. In the pericardial cavity, there were about fifty c.c. of dark amber fluid which gave on culture a pure growth of enterococci. The right auricle and its appendage were moderately dilated and filled with non-adherent blood clot. The right ventricular musculature appeared thinned. The tricuspid and pulmonic valves showed no gross pathology. There was a one and five-tenth by one cm hemorrhagic, friable vegetation on the aortic cusp of the mitral valve near the point of attachment of the valve, and a smaller vegetation to its right (Fig 1). A fragment of the larger vegetation was crushed and, on staining, revealed a gram-positive coccus. There was ulceration of the mitral valve with evidence of a mycotic aneurysm. Several two-three mm vegetations were present on the remainder of the mitral valve and on the subjacent endocardium. There was no evidence of thickening of the valve. The chordae tendinae showed no gross pathology. Numerous small, flat ulcerations were seen on the aortic valve, with narrowing of the ostium. The anterior leaflet was completely covered by shreddy, friable vegetations. Similar vegetations were also present on the other cusps and on the endocardium, there being several areas of ulceration, the largest corresponding on the aortic side to the larger of the two vegetations on the mitral valve. There was some thickening of the aortic cusps. The left ventricular musculature was paler than normal and thickened. Microscopically, there was a moderate degree of interfascicular fibrosis and edema. Aschoff bodies were not found.

Lungs. There was grey hepatization of the entire right lung and of the lower lobe of the left. There was a thick, purulent exudate over the right lung which gave on culture, a pure growth of the enterococcus. Microscopically, the lungs showed a lobar pneumonia.

Intestine. There were a few small foci in ileum suggestive of focal hemorrhagic necrosis with ulceration and an irregular flattened atrophic area in the upper rectum, suggestive of healed ulceration.

The anatomic diagnoses were

1 Vegetations mitral and aortic valves

- 2 Ulcerations mitral and aortic valves
- 3 Thickened aortic cusps
- 4 Pericardial effusion
- 5 Pleural effusion, bilateral
- 6 Pleuritis, bilateral, acute and chronic
- 7 Consolidation of lung, grey hepatization, bilateral
- 8 Infarcts liver, spleen, kidney
- 9 Healed ulcerations, rectosigmoid

Comment

The enterococcus is a gram-positive, pleomorphic coccus, usually growing as a diplococcus or in short chains. It is closely related to the *S. faecalis* and the *S. lactis aerogenes*. It grows readily on ordinary broth and agar, is an aerobe and facultative anaerobe, heat resistant, grows in ten to twenty per cent bile media, and ferments aesculin and salicin.

Fig 1 Arrow points to vegetations on mitral valve

It is necessary in the individual case to establish definitely that one is dealing with the enterococcus and not with an atypical streptococcus or pneumococcus.

The organism was called the enterococcus by Thiercelin in 1899 and is found as a saprophyte in the intestinal tract. It often invades the genitourinary tract, especially in females, and has been isolated from the urine and the genital passages. It may be present in the respiratory tract and can become pathogenic in any of these sites. It has been described as a pathogenic contaminant of war wounds and has been isolated in pure culture as the causative agent in a variety of diseases—pyelitis, ulcerative colitis, postoperative peritonitis, and generalized sepsis²⁻⁴. Felsen⁵ calls attention to the important role played by the en-

terococcus in chronic bacillary dysentery (chronic ulcerative colitis). He has recovered the organism from the intestinal contents, intramural abscesses, and the renal pelvis. He states that it is responsible in part for the chronic, non-specific intramural infection which occurs through the ulcers originally produced by *B. dysenteriae*. The enterococcus has been most frequently described in two conditions—postabortal sepsis and endocarditis. The portal of entry into the general circulation can usually be found at necropsy.

Wallach⁶ has pointed out several features of this form of endocarditis that are uncommon in those caused by the streptococcus viridans. These include a tendency to extensive infiltration of the heart muscle that accounts for the usual termination with myocardial failure and a tendency to formation of infected infarcts.

The enterococcus, as do other organisms, most commonly affects the left side of the heart and valves that have been damaged by previous infection. The disease may follow an acute or subacute course, the prognosis being bad. Auto-genous vaccines have been employed in treatment, especially by the French, in addition to the usual forms of supportive therapy including blood transfusions.

The case described above presented several unusual features. The endocarditis developed without clinical evidence of preceding cardiac damage and in a heart that presented no anatomic lesion except for slight thickening of the aortic cusps. There occurred extensive pneumonic involvement apparently of a recurrent type with a purulent exudate on one lung, giving a pure culture of the enterococcus. We have no information concerning the bacteriology of the inciting pneumonia which was extremely atypical in its onset and course. The enterococcus found in the pleural cavity was probably present there as the result of hematogenous infection.

Ulcerations, both recent and healed, were found in the alimentary tract, the normal habitat of this organism, and we must consider the possibility that, however these ulcerations were produced, the enterococcus may have entered the blood stream through these ulcerations.

FINDING TUBERCULOSIS WITH THE AID OF THE PRIVATE PRACTITIONER

Review of the Work of the Mott Haven Consultation Chest Service, 1934-6

HARRY T. PESSAR, M.D. and HERBERT R. EDWARDS, M.D., *New York City*
Physician-in-Charge, Tuberculosis Service, Mott Haven Health Center, New York City
Department of Health, Director, Bureau of Tuberculosis, New York City,
Department of Health

Introduction

In 1929 the first* Department of Health Consultation Chest Station for private physicians was set up at the Bellevue-Yorkville Health Demonstration in New York City. X-ray equipment for chest examination was installed here by the Demonstration financed by the Milbank Memorial Fund.

The experience gained here in metropolitan health administrative practices with services for the people and physicians of the district, has been an important factor in the formation of plans to establish such services in other districts throughout the city. Under the leadership of Shirley W. Wynne, then Health Commissioner of New York City, six other Consultation Chest Stations for private practitioners started operation in various districts of the city. The Academy of Medicine and the County Medical Societies have heartily endorsed this plan.

The approval for the establishment of this type of community health service is based on the following considerations:

1 That the family physician is a very important factor in any community health program, and that any effective tuberculosis work cannot therefore be undertaken with any hope for success without his active and intelligent cooperation and support.

2 That to find early cases of pulmonary tuberculosis, the physician must be provided with complete and easily available modern diagnostic facilities to supplement his own resources.

3 That through the Consultation Service

the Health Department will establish and maintain new contacts with a large number of private practitioners and thus constantly expand its influence in the direction of prevention, and the promotion of better community health.

The Consultation Chest Stations are not intended to provide free chest x-rays for the patients of private physicians. Rather they are designed to give the family physician a chest consultation service for those of his patients who can afford to pay his fee, but are unable to meet the cost of an examination by a specialist.

Aims

In the operation of these stations our aims are:

1 *Tuberculosis case finding*, by providing modern facilities and trained personnel for the examination of patients who present diagnostic problems in tuberculosis.

2 *To find early tuberculosis*, by providing facilities for the examination of contacts to cases of pulmonary tuberculosis which are diagnosed at these clinics.

3 *To control household epidemics of tuberculosis*, by the assistance given to the family physician in arranging for institutional care for those in need of such care.

It should be emphasized here that the plan of consultation chest station is not antagonistic to the economic or professional status of the family physician, rather it is a realignment and strengthening of the general practitioner's resources for effective tuberculosis work, so that patients of moderate means may be encouraged to make frequent consultations with their family physician.

The extent to which these aims and objectives are achieved is told in the following account of the work of the Mott Haven Consultation Chest Station during

*The first Consultation Chest Service for private physicians in New York City was started in June 1924 in St. Johns Hospital, Long Island City, under the sponsorship of the Queensboro Tuberculosis and Health Association. It is still in operation.

TABLE I—NUMBER OF PATIENTS REFERRED BY INDIVIDUAL PHYSICIANS

ing the three year period 1934-1936. We should like to point out here, however, that a great deal of what is done in this clinic has been accepted by the physicians on the same basis as other diagnostic procedures furnished by the Department of Health in other communicable diseases, such as the examination of a throat culture for the diagnosis of diphtheria, the blood for syphilis, etc.

The Mott Haven Consultation Chest Station for private physicians was opened

in June 1930. According to the Federal census of April 1, 1930, the Bronx had a resident population of 1,265,520, of which number 477,342 or thirty-eight per cent were foreign born. Considering predominant nationalities and racial groups, it is found that 45.28 per cent of the population were Jewish. A little more than one-half of the Jewish population were foreign born, chiefly from Eastern European countries. About fourteen per cent of the foreign population were Italian, seven per cent Irish, about eight per cent German, and five per cent English. Only one per cent of the total population were Negro.

Clinic Routine

Patients for this service are assigned appointments over the telephone through their physicians for Monday, Wednesday, and Friday. Upon admission the patient is given a thorough chest examination which includes a physical examination of the chest, fluoroscopy, and the taking of x-ray films, sputum examination, and in the case of children a tuberculin test.

Generally a report of the result is mailed to the physician within twenty-four hours following the patient's visit to the clinic. This report includes

- 1 A resume of all relevant data in the clinical history

- 2 An enumeration of all important physical findings

- 3 A complete description of the x-ray pathology of the chest.

- 4 A diagnosis and opinion

- 5 An offer to the physician of our facilities to help him in (a) the hospitalization of all cases needing such care, and (b) the examination of all contacts to diagnosed cases, with a report of the findings

No information or advice is given directly to the patient. All information regarding the results of the examination, after the final report has been sent to the referring physician, must come from him. It is definitely understood that after the investigation and the submission of the report, the further handling and supervision of the case is entirely the duty and responsibility of the family physician. Cases in which the patient

has made a change of doctors, the case records obtained for one physician are not available to a new physician without the consent of the original physician.

The popularity of this service among physicians, and the extent to which it is utilized by them is shown in Table I.

An examination of Table I shows that of the 1,677 Bronx physicians listed in the 1934 N Y State Medical Directory, 433 or 25.8 per cent availed themselves of the consultation service, of the 1,751 Bronx physicians listed in 1935, 487 or 27.8 per cent used the service, while of the 1,750 physicians accredited to the Bronx in 1936, 481 or another 27.8 per cent made use of the service. The popularity of the Chest Consultation Station is thus made evident. It is a reasonable assumption that such popularity could not develop except on a firm foundation of mutual confidence.

Results of Work

During the three year period 1934-1936, the total number of patients referred to the clinic by private physicians was 5,521. On the basis of Table I it will be seen that these patients were referred by 1,401 physicians, an average of four patients to a physician.

The volume of work for each year is indicated in Table II. It will be noted that 6,533 examinations of 5,521 individuals were necessary to arrive at a final diagnosis, a ratio of 1.2 examination per patient.

In the group examined 844 cases with tuberculous pulmonary lesions were revealed. Of this number 409 were classified as clinically active cases, while 435 were inactive cases.

It will be seen from Table III that of all the cases diagnosed active pulmonary tuberculosis 158 or thirty-nine per cent showed bacillary sputum on the first routine smear examination.

Classifying the 409 clinically active cases in accordance with the accepted classification of the National Tuberculosis Association, it is found that no more than twenty-five per cent of these were in the minimal stage, while the remaining already had the disease in an advanced stage (Table IV).

Of the 435 inactive cases, 114 showed

fibrocalcereous infiltration in the lung parenchyma, 145 had latent apical nodules, or fibrotic strands. Evidence of primary infection as manifested by Ghon foci and lymph node involvement, all showing calcium infiltration were found in 176 cases (Table V).

Notwithstanding the fact that 435 of the 844 tuberculous individuals were found to have the disease in a clinically inactive form, they nevertheless constitute an important group from the public health standpoint. Practically all of these cases represented arrested and latent lesions of the reinfection type which are prone to reactivation, while their discovery created a possibility for medical supervision which might conceivably prevent such an occurrence.

Clinically important lesions of nontuberculous etiology were found in considerable numbers. Among the 5,521 patients examined by us a significant proportion showed abnormal cardiac silhouettes, with secondary changes in the lungs in the form of interstitial fibrosis, brought about by chronic passive pulmonary congestion. In addition, many cases of nontuberculous pulmonary fibrosis due to preceding or concurrent suppurative processes were revealed, as well as ten cases of nodular fibrosis, the result of silica dust inhalation. The nontuberculous pulmonary lesions included besides thirty-three cases of bronchiectasis, thirty-four of unresolved pneumonia, fifteen tumors, eleven of aortic aneurysm, and four of pulmonary abscess.

The search for early tuberculosis among susceptible contacts to known sources of infection, offers a most promising field for successful case finding work.

It is in this group that we can work with the full expectation of finding early and unrecognized disease.

There were 1,336 contacts in the households of the 409 individuals who were found to have tuberculosis in a communicable form. Of this number 342 adults and 127 children were exposed in homes of "open" or positive sputum cases.

Table VI shows the total number of contacts, and the number of those exposed to positive sputum in their homes,

The results of our work among the contacts is shown in Table VII

It is of interest to note that as shown in Table VIII of the forty-six secondary cases of clinical tuberculosis discovered among the contacts, forty-three were found in adult contacts, and only three in children contacts. Evidently the reinfection or superinfection type of pulmonary tuberculosis is a disease predominantly and characteristically found in adults

Over sixty-three per cent of all known contacts to our diagnosed cases were examined by us, and among these we obtained a yield of five per cent of secondary cases. Such a significant yield may be ascribed to the fact clearly shown in Table VI, that thirty-five per cent of all the contacts were exposed in families of positive sputum cases

The importance of familial contact with open cases as a factor in the development of tuberculosis cannot be overemphasized. According to Pope,¹ persons so exposed show a tuberculosis incidence variously estimated at from five to ten times that of the general population. His experience in the examination of 150,000 children in the school clinics of Massachusetts showed that the incidence of pulmonary tuberculosis among grade school children with a history of family contact was eight times that in children without such history, and twenty times greater in high school student contacts, than in students with no contact history

We helped in the hospitalization of seventy-seven private physicians' patients whom we diagnosed active pulmonary tuberculosis. Since hospitalization of the tuberculous is one of our primary objectives, this was accomplished in nineteen per cent of the 409 cases diagnosed by us

An inquiry into the reason which caused the patient to desire a consultation with his physician brought out interesting sidelights on the problem of tuberculosis case finding (Table VIII)

Cough was given as the chief reason for the patient's visit to his physician in 278 instances, or in sixty-seven per cent of the cases. Hemoptysis was complained of 126 times, or in thirty per cent of the cases. Loss of weight and

chest pains were named 217 and 114 times respectively as the chief complaints. During 1936 when we had the largest number of far advanced cases, weight loss was more frequently complained of than in any of the preceding years

It is quite evident that the average individual does not consult his doctor before his disease is serious enough to cause troublesome or alarming symptoms. Since early tuberculosis rarely gives rise to serious symptoms, case finding efforts among clinic patients usually lead to the discovery of many cases in an advanced stage of the disease, and but few minimal cases. This has been the experience of all tuberculosis clinics and hospitals

DISCUSSION

The Mott Haven Consultation Chest Station constitutes an important part of the official set-up for tuberculosis control in a community with an estimated resident population of 1,441,532 (1936). During this year the official tuberculosis register showed a total of 2,800 cases, of which 1,123 were new cases of pulmonary tuberculosis added to the register during 1936. There was a total of 4,364 known cases of tuberculosis in the Borough during this year

The results of our case finding work in this clinic, serves to re-emphasize the difficulties connected with tuberculosis case finding work.

Clinical and pathological experience tell us (a) that the early tuberculous lesion does not usually give rise to cough, blood spitting, loss of weight, and night sweats, and (b) that when tuberculosis is the cause of marked disability for the relief of which the patient will seek advice from his physician, the disease is already in an advanced stage

P. P. McCain² of North Carolina Sanatorium in summarizing the problems involved in the various phases of the disease, points out quite correctly that in minimal tuberculosis, the earliest clinical form of the disease in the adult, there are no symptoms in most cases, and physical signs are either indefinite or entirely absent. Even in moderately advanced tuberculosis the symptoms may

be insignificant even when positive sputum is present

Our experience in the Consultation Chest Clinic based on the results of medical examinations of thousands of people, further corroborates and supplies factual data in support of these fundamental concepts in clinical tuberculosis

Practically every one of the patients who was found to have active tuberculosis consulted his doctor originally because of serious functional disturbances, manifested by troublesome, prolonged cough, or hemorrhage, chest pain or debility. Over seventy-five per cent of the 409 individuals diagnosed pulmonary tuberculosis were in an advanced stage, and more than one half of them had tubercle bacilli in their sputum

These findings are in general agreement with results of surveys by most investigators of this problem. The survey³ by the Council on Medical Education and Hospitals of the American Medical Association revealed 86.9 per cent of 66,261 tuberculosis patients in an advanced stage of the disease

Notwithstanding our failure to discover a greater percentage of cases of early tuberculosis, the Consultation Chest Station is proving itself an important method in tuberculosis case finding and control. This is shown not only in the discovery of the 409 previously unknown active cases of pulmonary tuberculosis, but also in the diagnosis of the 435 latent and arrested cases

The potential significance of latent pulmonary tuberculosis was studied by McPhedron and Opie.⁴ These authors show that latent tuberculous lesions of first infection type which on the roentgenogram appear as strand-like shadows representing fibrous tissue, may subsequently develop in thirty-five per cent of the cases into clinically manifest pulmonary tuberculosis. Latent apical lesions of the reinfection type, especially when located in the subclavicular region, is regarded by them of such important significance that the same treatment is advised as in the case of clinically manifested tuberculosis, until serial x-ray studies prove that the lesion is not progressive

The frequent reactivation of arrested lesions, and the need for careful medical

supervision of these, is a matter well-known to most clinicians and phthisiologists to require further discussion here

In the investigation of the 5,521 patients referred by the general practitioners for a chest examination because of chronic respiratory symptoms, we found 303 chronic, nontuberculous pulmonary conditions, which previously were unrecognized and untreated. In this way we made another important contribution to the improvement of the general state of community health in the Borough

If the Consultation Chest Station did nothing else but perform the fundamental services in tuberculosis control thus far

TABLE V—NONACTIVE TUBERCULOUS LESIONS FOUND IN 5,521 PATIENTS

discussed, it would amply prove its usefulness. But, it is in the results of our creditable work with the contact group of the active tuberculosis cases, that the great usefulness of the Service is making itself evident.

In studying a series of pulmonary cases, Zacks⁵ found that two out of three patients were exposed to infection in the home, and despite the fact that less than one half showed either symptoms or physical signs at the time of the diagnosis, twenty-four per cent were dead within five years.

Amberson⁶ who has had considerable experience in group survey work, estimates the percentage of new cases resulting from large surveys of population groups with the rapid paper film method at one and a half to two per cent of the number examined.

The findings of the forty-six secondary cases of early tuberculosis with no symptoms constitutes an important public health measure for combating tuberculosis, since prompt and proper treatment of early lesions surpasses any other means of restoring such patients to good health. It is besides the best means for preventing cavernous phthisis which is the source of most tuberculous infection.

The fact that 850 (sixty-three per cent) of the 1,336 contacts to the diagnosed cases were referred for examination, which in the case of children, includes tuberculin testing and x-raying, may serve as a measure of the effectiveness of our educational work concerning modern methods for the examination of contacts.

Summary and Conclusions

1 The Mott Haven Consultation Chest Station is proving itself a very

effective instrument for case finding work.

2 During the three year period, 1934-1936, 409 cases of active pulmonary tuberculosis, of which 158 had positive sputum, were found among 5,521 patients referred by private practitioners. This represents a yield of 7.4 per cent of new cases discovered by this method. In addition forty-six previously unknown secondary cases were discovered upon the examination of 850 household contacts in families of the 409 individuals originally diagnosed at this station.

3 Significant nontuberculous chronic pulmonary conditions were found in 303 individuals. These were unrecognized and untreated before they were diagnosed by means of the Chest Consultation Service.

4 For the purpose of control, we rendered the additional service of helping in the hospitalization of seventy-seven patients with active pulmonary tuberculosis in a communicable form, at the request of their private physicians.

5 The Consultation Chest Station by its friendly and helpful cooperative service to physicians is building up an efficient, constructive, and active joint relationship between the Health Department and the private physicians of the community for the purpose of better tuberculosis control and improved community health.

A Correction

Several editorial errors appeared in the article by Joseph Millett, B. S., M. D., which appeared on page 1743 of the October 15 issue of this JOURNAL.

1 The title of the article should have been "Sulphanilamide in Type 3 Pneumococcus Pneumonia."

2 (p 1743, right hand column, in para-

graph titled *Clinical course*) In the third line, "on the third day" should have been omitted.

3 (p 1744, second line, first paragraph, left hand column) "horse" should have been omitted.

We regret these errors and are glad to make this correction.

ILEOSTOMY IN FULMINATING ULCERATIVE COLITIS

Subsequent Closure and Recovery

CLYDE O BARNEY, M D and JOHN C M BRUST, M D, *Syracuse*
From the Surgical and Proctologic Services of Syracuse University Hospital

It is generally understood and accepted that uncomplicated chronic ulcerative colitis is a medical problem. Certain complications may make surgical intervention imperative. Rarely the initial onset of the disease is so devastating that ileostomy appears as the only procedure that can save the patient's life. In such instances ileostomy entails a very high mortality rate. It has also been shown that once an ileostomy opening has been established in this disease it is practically always permanent. The case we report is interesting because of the unusual severity of the initial attack. The victim was an individual in whom emergency ileostomy was performed and who was fortunate in that today, fourteen months after subsequent closure of the ileostomy he is subjectively and objectively free from the disease.

Case Report

The patient, a young man, age nineteen, who lived in northern New York State, was admitted by ambulance to the Medical Service of Syracuse University Hospital on December 5, 1934. He appeared desperately ill with obvious dehydration, anemia, and a mouth temperature of 103.2°F. The history obtained from an uncle was that following a mild "cold" he began to pass watery stools with abdominal cramps. The onset was twelve days prior to admission. The diarrhea increased in severity and soon profuse quantities of blood, pus, and foul smelling fecal material were passed. Some vomiting had been present for two or three days. His birthplace was Brazil, but he had lived in New York State for sixteen years. He had worked in a fruit store until his illness occurred.

Amebic dysentery was at once considered but repeated warm stool examinations revealed no ova or parasites. He was too ill for either sigmoidoscopic or roentgenographic examinations. Hemoglobin estimation was 122 gms and his erythrocytes numbered 3,800,000. Leukocytes numbered 35,100 and the polymorphonuclear cells comprised eighty-six per cent of the total.

On admission intravenous dextrose in saline was administered and he was twice

given 400 c c of whole blood on the succeeding two days. Emetine hydrochloride given for three days was of no apparent benefit. Paregoric, bismuth, kaolin, and other medicines did not check the diarrhea. Despite all measures he grew rapidly worse and the generalized abdominal tenderness became so marked that impending perforation of the colon was suspected. He was having thirty to forty bloody passages in twenty-four hours.

The Surgical Service was requested to see this patient with the view of considering ileostomy as a last resort. Inasmuch as the patient was losing blood per rectum almost as fast as it was given by transfusion, we felt that in order to save his life it was necessary to put the whole colon at rest by performing ileostomy.

On December 13, under general anesthesia a loop of ileum was brought up thru a lower right abdominal incision over a glass rod. This was at a point about six inches proximal to the ileocecal valve. The ileum appeared normal as did the appendix. The next day, the loop of ileum was opened by cautery, thus producing a double opening so that the bowel could be irrigated either proximally or distally as desired.

Following operation he was critically ill for three days. His temperature slowly fell and the general condition gradually improved. After five weeks he was having six to eight liquid passages daily through the ileostomy stoma and suffered only occasional abdominal distress. By January 21, 1935 he was on a suitable high caloric, low residue diet supplemented by iron and yeast. At the time of his hospital dismissal, February 6, the rectal discharges numbered eight to ten daily consisting of mucopurulent material and blood. He went home to rest and gain in strength.

He was first seen by one of us (J B) April 5, when he returned to the hospital for an examination. His rectal discharges numbered six to eight daily with some blood and although he was partially ambulatory he felt very weak and tired. Some left-sided abdominal cramps persisted especially noted in the morning. His weight was 129 pounds. The ileostomy was functioning satisfactorily.

Sigmoidoscopic examination showed the typical picture of the so-called idiopathic,

or, as Bargaen terms it, bacterial chronic ulcerative colitis. The mucosa was visibly granular and finely ulcerated for a distance of twenty-six cm. There was moderate contraction of the lumen and the entire mucosa bled easily on slight trauma. Cultures were taken from the ulcer bases into brain broth media and the laboratory reported a heavy growth of the diplostreptococcus of Bargaen.

He was at once placed upon the regime that has been used at the Mayo Clinic, namely adequate diet, antilucerative colitis serum intramuscularly, after fourteen days an autogenous vaccine was administered every five days. The response was striking. Rectal discharges diminished and after four weeks practically no blood was noted. His weight increased as did his appetite and in August, four months after this attempt at specific therapy he appeared much improved.

The vaccine was given periodically until December 14, when he re-entered the hospital because the proximal loop of ileum was evaginating thru the ileostomy opening. When on his feet for very long this piece of intestine protruded about eight inches causing pain and some bleeding at times. Sigmoidoscopic examination showed the rectum and sigmoid to be practically healed although there was some scarring and thickening of the walls. The lumen appeared ample in diameter and no evidence of fresh or secondary infection was present. The skin about the ileostomy opening was sore and irritated. The patient was kept in bed and aluminum paste applied to the skin. On December 19, a right angle clamp was applied to the two adjacent walls of the ileostomy openings. This was tightened each day and finally it sloughed loose December 29. After that he began to pass part of his feces per rectum. The patient desired to go home and he was discharged January 15, 1936.

He was readmitted February 3. His abdomen was scaphoid. The skin about the wound was well-healed and in good condition.

For many weeks he had been requesting that closure of the ileostomy stoma be attempted although the dangers were explained to him. However, since some plastic type of operation was needed and because the distal colon appeared practically normal it was felt that after suitable preparation closure might be attempted. Preparation consisted of nonresidue diet, saline enemas, transfusions of whole blood, and bed rest. Roentgenograms of the colon showed slight narrowing distal to the splenic flexure but revealed neither active infection, polyps nor

strictures. Ulcerative colitis serum was given intramuscularly twice daily for five days.

On February 5, under general anesthesia an incision was made around the ileostomy opening, the bowel was dissected away from the abdominal wall, and freed from the peritoneum. The edges of the ileum were trimmed back to fresh tissue and then sutured. Two layers of chromic #0 on atraumatic needles and one layer of interrupted silk were used. The bowel was returned into the abdominal cavity, peritoneum and fascia closed, and the remainder of the wound left wide open. A transfusion was administered postoperatively and the specific serum continued twice daily. Convalescence although rather slow was uneventful and he was dismissed from the hospital February 26. The wound healed by granulation, and has remained firm and well-healed.

One month later he reported that his stools numbered three or four daily with no visible blood. There was no abdominal distress. He was advised to continue receiving the vaccine every three or four months for periods of six weeks.

He was last seen by us April 12, 1937 at which time he weighed 154 pounds. His color was good and he stated that he was free from any bowel symptoms. Sigmoidoscopic examination showed a normal rectum and sigmoid except for slight thickening of the walls. He was again advised to receive the vaccine periodically and to report back every six months.

Comment

This case illustrates the occasional severity of ulcerative colitis and the need for cooperation between internist, surgeon, and proctologist in properly treating such patients. Bargaen, Brown and Rankin¹ show conclusively that ileostomy is rarely indicated in this disease and they state that once established it should be permanent. With these general conclusions we agree and we present this report to show that exceptions to these rules may arise. We feel that ileostomy saved this patient's life, but we also feel that the medical measures as previously outlined by Bargaen and his coworkers were the ultimate deciding factor in the restoration to health.

Preventive Medicine

Medicodental Cooperation in Preventive Medicine

CHARLES H. GOODRICH, M.D., Brooklyn

Presidential Address

"The human body is a complete organism with the function of each part dependent on that of another or others" (Rushing—*Tri-State Med Jnl*, Jan 1936)

"Any physician (and/or dentist) should be able to think of the whole patient" (C. H. Mayo, *Mouth Health Quarterly* 1934-35, April 1935, p. 6)

* * *

Licensed to practice medicine in the State just before the turn of the century we were not then conscious of any cooperation between physicians and dentists. Of oral diagnosis and surgery, physicians and surgeons knew little as compared with now. Dentists knew little and practiced less asepsis. A surgeon once introduced our first Brooklyn dentist as "The only one in Brooklyn who boils his instruments." At about this time we saw extractions by expert specialists using instruments selected from the dusty shelves of an open case. Equally asepsis-scorning were some medical specialists. A famous ophthalmologist conducted clinics in New York and ridiculed asepsis and antiseptics as taught us by our enthusiastic surgeons. He would say, "Now a drop of antiseptics (with a well accented wink)—a little boric acid in the eye—then rub your knife on your kerchief—friction is the best sterilizer—then insert the knife into the eye muscle—so!"

Of some foul mouths sparsely inhabited by broken, jagged stumps in pus-filled sockets the physician might say "Better have those rotten things out so that you will not swallow that pus." Or if a dentist discovered a benign or malignant epulis he might refer his patient to a surgeon for its removal. That, however inadequately, affords an illustration of our general recollection of medicodental cooperation as practiced before the turn of the century. It seems conservative to

declare that then we were two separate but not unsympathetic professions, for common knowledge of anatomy and physiology, and ambitions to relieve suffering brought us loosely together. The laboratories of bacteriology and biochemistry were in their infancy and knowledge remained sketchy and elementary. The Roentgen-ray was unknown to the rank and file of both professions. Pathology was more competent but still in an adolescent period. Diagnosis was largely based on clinical observation of the patient's anatomy and physiology, with the help of urinalyses, blood-counts, and tissue sections *after* treatment, for biopsy was not then practiced.

The relation of diet to disease was understood partially—perhaps the difference with our present knowledge is only in degree—but how diet influenced dental conditions was rarely if ever considered by the *medical* practitioner. Many a handsome mouthful of teeth was ruined by the physician's grand good medicine without a thought as to the deterrent influence upon the future health of the patient—when neutralizing influences could well have been applied. And, if we mistake not, dentists knew little of dietetics or practiced their knowledge meagerly. Vitamins were unknown. Calories were mentioned occasionally but rarely counted. Haig and Fagge, eminent Englishmen, preached that animal flesh and acid fruits were largely the cause of rheumatism and allied disorders. Lack of cooperation in those days was not due to the character of the men or to their grasp of the knowledge of the day, but to the lack of facilities now at our command.

Today Medicodental cooperation in the treatment of disease is well-established. Cooperation in treatment is so frequent and cordial that we might almost be warranted in advertising the fact were professional advertising ethical and permissible. This has been evolved with the extended use of bac-

Delivered at the Joint Annual Meeting of the Seventh District Branch of the Medical and Dental Societies of the State of New York, Geneva, September 22, 1937

teriology, biochemistry, biopsy, pathology, and allied research by both professions. The increase of complete examinations, including the mouth, by physicians has had its influence. In the earlier days major emphasis was placed upon treatment. Gradually prevention has come to a prominent position. Both dentists and general surgeons have developed more technical skill in operations upon the mouth until an oral surgeon may be a doctor of medicine or a doctor of dental surgery, and in some instances both.

Two professions formerly separated have found a common basis for understanding and mutual appreciation. This changed attitude has progressed so well due to the efforts of far-seeing leaders in both groups who have sounded that spiritual altruistic note "The welfare of the people." Increase in understanding diet in relation to dental conditions, the discovery of the effects of vitamin values upon the entire body, and the expanding conception of the importance of focal infection have been patent influences.

Preventive medicine comprises a large field of effort. Unprogressive thinking would limit its application to those specific measures known to prevent certain diseases. These need not be emphasized but merely mentioned in passing. Physician and dentist alike are interested in prevention and can ethically encourage the timely use of every technic to that end, and when occasion arises, may serve each other as well as the patient.

The importance of nutrition in the prevention of disease must be considered from the date of birth or within two or three days afterward. Indeed, with adequate laboratory facilities available, it may often begin before birth. In very early life the development of good tissues, including teeth, can be provided with very simple study of our little patient. Here, as later, vitamins which are evidently lacking can be supplied. Well-balanced diet can be safely provided for the very young as well as all succeeding ages and can be regarded as a measure of disease prevention. Take for instance the consideration of calcium deficiency, or abnormal blood-cholesterol, or blood-sugar, or urea-nitrogen, or of abnormalities in blood-counts, without apparent disease. Evident nutritional deficiencies in the teeth observed by the dentist can be the base of joint efforts by physician and dentist. Reasons for altered feeding of the child or adult may be

discovered by the dentist in the gums or mucous membranes of the mouth which demand cooperation for fulfilling effective preventive measures. The physician may early discern defective tooth development, unregarded by parents, which requires the dentist's cooperation to competently prevent later disease.

Along with this careful biochemical consideration of foods there often comes the need of observing mechanical difficulties which involve proper food-cutting and grinding. That this orthodontic angle requires earlier attention than it often receives is undoubted. Gradual and increasing deficiencies of nutrition can thus be avoided. You may prevent gastrointestinal irritation by insufficiently divided foods, as well as avoiding advanced malocclusions, teeth crowding, and other deformities. These frequently cause self-consciousness, various mental complexes and inhibitions. The physician should often discover these matters and can render magnificent service by insisting upon proper dental regulation.

This nutrition problem is so important in preventive medicine and dentistry that we should jointly dedicate some fraction of our time to adequate and accurate study of foods, their values and resultant health influence, avoiding those occasional noisy enthusiasms, the value of which are soon disproven. History tells us that in the seventh decade of the last century an eminent physician declared that cancer, at least of the stomach and intestines, was caused by the eating of tomatoes. For some years his dictum, founded on superficial and insufficient data, was accepted. The brilliant spectacle of one hundred and fifty tomato juice cocktails which we beheld on a splendid dinner table recently shows one change in knowledge of food values.

The prevention of caries of the teeth is an important subject for physician and dentist. In 1530 a book on teeth was published which warned people that to preserve teeth "avoid use of foodstuffs which are sweet and easily retained in dental spaces" (Wallace). This was curiously prophetic for without much knowledge of chemistry of foods, certainly none of lactic acid fermentation, and with no knowledge of modern bacteriology of the mouth, this ancient writer had hit upon one of the true factors now established as a basic cause of caries in civilized moderns, namely, carbohydrates.

Here curiously the same dietetic etiology has been determined to be a factor in the chronic forms of arthritis. Heredity in both instances is largely discarded. Family habits of diet and other influences are at fault rather than physical inheritance, if we except syphilitic and tubercular families. In dental examinations of multitudes of school children in recent years it has been found that "the better the school the worse the teeth." Thus it has become axiomatic that caries is a luxury disease as well as a deficiency disease (Wallace). In any event, physicians should examine mouths for caries and gum conditions. Here, small but powerful diagnostic lights sharply increase our usefulness. Dentists and physicians should study applied dietetics and work together along this line of prevention. In the meantime, we must all acquire knowledge of the chemical and bacteriological processes by which carbohydrates are converted into acids which produce caries.

Parallel accompaniments to dietetics are certain widely used poisons such as coffee, tea, alcohol, and tobacco. How easy it is for people to habituate themselves to excessive daily consumption of these substances is too well-known to discuss here except to remark that we are derelict in our duty if we do not reveal to our patients the advantage of abstinence or at least extreme moderation in their use.

There is a vast field for preventive medicine in the study of other poisons easily absorbed in various occupations and in daily domestic life.

Latent focal infections of teeth and gums are known to be potential causes of disease. We realize that dentists are not unanimous in their opinions regarding devitalized teeth as potential or definite dangers to health, and we must await their unanimity before medical men can vote as one. However, it is probably a fact that latent focal infections lurk in the mouths of many persons who seem to be healthy today who, in the not too distant future, will be diseased as a result thereof. Here, indeed, is a vast field for cooperation. Here, physicians can help by requiring dental x-ray films in every periodic health examination and wherever any minor disorder gives reason for such recommendation. Haden says "Too often physicians depend entirely on radiographic findings." Here dentists can help by always making complete films of both jaws when

only one or two teeth are under suspicion, and for otherwise thoroughly testing for devitalized teeth in various ways. Then, off to the physician with the films and duplicate reports for his records. Only by the adoption of these practices can consistent prevention of disease be fully accomplished. To realize how much can be done along this line we have only to scan the bacteriologically proven records of the association of abscessed teeth and pyorrhea alveolaris with various diseases.

Haden, in his work on dental infection and systemic disease, recounts proved cases with identical or like lesions in rabbits inoculated with culture from tooth sockets in thirty-five cases.

Few physicians realize the dangers of infection from tooth or filling fragments left in jaws after tooth extraction. Both dentists and physicians should assure the complete elimination of this cause of potential infection by careful followup examinations.

Oral hygiene as practiced and taught by the accomplished dentist of today is an important phase of preventive medicine. The tonsils are near the teeth. We should be anxious to have the dentist's examination discover infected tonsils. His transillumination or his olfactory sense may locate a foul sinusitis, draining perhaps, but a potential sewer of infection.

In dealing with all forms of latent focal infection our cooperation will not be complete without the help of the bacteriologist and pathologist and biochemist—really a quintuplet cooperation.

Annual or semiannual periodic health examinations should be constantly urged upon patients by both physicians and dentists, these are flanking attacks at a time when patients think they "do not need examinations." For Lo, they feel well! And if they do capitulate, we must be ready with schedules, and record blanks and equipment, material and mental, to do thorough work, with no sins of omission. Many years ago we listened to a remarkable sermon by a little gray bearded old clergyman, as old as most of the members of the Supreme Court. His main point was that our sins of commission in this life were insignificant as compared with our sins of omission. He likened the sins of commission unto an anthill as compared with the highest mountain of the Himalayas.

representing our sins of omission Perhaps our sins of omission in preventive medicine are as great. On the discussion of methods of such examinations we could profitably spend much time together When this type of examination is in popular demand, many will spend half of their time upon it, and some will specialize exclusively in it. It will become the keystone of preventive medicine in the individual We cannot effectively and completely practice this without each other

In regard to cooperation in research we refer you to Dean LeRoy Miner's eloquent and comprehensive assertion "It (research) is constantly crossing the lines of departmental and professional knowledge and as fast as it expands draws men of different faculties and diverse sections of science into closer cooperation" Cooperation in research can be invaluable, for there are problems of prevention that can only be solved by the merging of interests in this work Take the relationship of duodenal ulcer to focal infection from teeth, tonsils, sinuses, and dermatological lesions What more fruitful field? And, there are a hundred such waiting

It seems wise and essential that we live together administratively in our search for the great truths of science. American medicine is organized with the county society as the unit and districts composed of several units in the State Society Dental organizations are similarly set up Why not unite at our centers of thought and discussion? If county or district medical and dental societies could join their libraries together, better service at less cost would be assured and each could have available the works of the other, and avoid much duplication (Witness Dr Weinberger's magnificent work for the First District Dental Society) If society offices and meeting rooms were under one roof we would meet oftener and learn more of each other's work Dwelling together officially would facilitate our common effort to secure health legislation that is desirable for the people of the State and to defeat the undesirable

We have learned to think in terms of the entire State Our horizon grows and expands as our work and duties expand Therefore, it is surely true that

if all of both professions devote a little more time to the professional work that deals with the large field, we shall also grow to think more faithfully and effectively for the individual in preventive medicine

We have considered nutrition, dietetics, mechanics of mastication, certain poisons, caries, focal infection, research, and the uniting of administrative offices and libraries

Thus, we have indicated features of our various professional works in which cooperation in preventive medicine and dentistry will always be of special value to the public We say "special value" What we mean is more nearly complete values in diagnosis and prophylaxis As golf teams, we approach the green with common objectives Let stymies be ruled out. We are playing as a team Our score counts for everybody concerned Let strategy always be unselfish Thus we will inspire and deserve the confidence of our people and, better still, we will prevent disease Let us invariably adopt the superlative ethics and courtesy of both professions and thus render maximum partnership service in the preservation of good health which is preventive medicine Give us twenty years of this and the incidence of and mortality from insidious focal infections and the so-called degenerative diseases will largely decrease Comfortable life will be prolonged and once more will be demonstrated the value of cooperation by idealistic scientists

When we have cooperatively told the people what to do to preserve good health, the next step is to induce them to do it. This will require some brilliant lady or gentleman to present another chapter on cooperation If we cooperate effectively for a long enough period we may inspire even that superlative degree of confidence exhibited by the wife of a carpenter who fell from a scaffold The carpenter was ambulated to a hospital The hastily summoned wife sat tearfully on one side of the bed, the house surgeon stood on the other, each holding a hand of the patient. After a while the house surgeon said, "I am very sorry, Madam, but your husband is dead" The supposed corpse spoke up saying, "No, I ain't either" Then the wife said "Lie still Tom, the Doctor knows better than you do!"

We will repeat the two quotations uttered at the beginning

1 "The human body is a complete organism with the function of each part dependent on that of another or others"

2 "Any physician or dentist, or any

physician and dentist, should be able to think of the whole patient"

May we add a third? The great Theodore Roosevelt once said—"Together is the grandest word in the English Language"

Medicodental Cooperation in General and Special Practice

THEODOR BLUM, DDS, MD (Penna) Universae Medicinae Doctor (Vienna)
FACD, FACS, FICD, *New York City*

The necessity and importance of medicodental cooperation is conceded by every progressive physician and dentist. However, there are still groups of both professions who firmly believe that every dentist should be a graduate of a medical school. Such a physician-dentist, they assume, would understand the many and various medicodental problems and be able to solve and treat them, reducing to a minimum the necessity of cooperation. I shall take quite a few moments to prove the impossibility and impracticability of the physician-dentist, although it already has been proven by experience in those European countries, in which apparently only a physician is permitted by law to practice dentistry. It may be worth mentioning at this time that in all those countries there exists also the dental technician, who by law is granted the privilege to practice dentistry in nearly the same way as the physician and has as a rule a much better income—and maybe deserves it. The European dental education is far below the American—the European dentist must complete the last two years in an American dental school before being admitted to the New York State Board Examination.

Let us now return to the American system of medical and dental education. Before entering a medical school the student must have completed a four year college course. I personally do not agree and have previously called this college prerequisite the great American economic waste, being of the opinion that a well-arranged high school curriculum should suffice and that the student when entering the professional school should be about eighteen years of age. At any rate,

in accordance with the present thoughts one must figure on four years of college, four years of medical school, at least one year internship, and a minimum of three years in general practice. In other words, the physician who expects to specialize will be twenty-nine years of age. Will he then be well-prepared to give an authoritative opinion on diet, cardiac or rheumatic conditions, nervous disturbances, digestive disorders? And you notice probably I have not mentioned the more commonly recognized specialties like rhinology, otology, ophthalmology, dermatology, etc. But let us assume he were able to do so, he is now twenty-nine years old, his hands cannot easily, if at all, be trained to do mechanical work, which after all comprises a large part of dental practice. Furthermore, two years would not suffice and three years surely are necessary for his dental studies. He is now thirty-two years old. Still he is not efficient as a dentist, he needs another three years at least of this special dental practice before he is admitted to a society of medical specialists in accordance with the laws made by every society of medical specialists. And what a poor specimen of a physician he will make beginning the practice of his specialty when he is thirty-five years of age. You may say now, let him be a stomatologist—whatever that may mean—and have a mechanic attend to the dental work! That is exactly what happened in these European countries. The dentists became dependent upon the mechanics, the mechanics increased in numbers and became powerful enough to have laws passed to permit them to practice dentistry. It is true that in some places they will not get new licenses, but that will make

Read before the Annual Meeting of the Seventh District Branch of the Medical Society of the State of New York and the Seventh District Branch of the Dental Society of the State of New York, Geneva, September 22, 1937

it still worse, because then the people will only receive very, very little good dental care

The best way out of this dilemma is not the physician-dentist, but more medical education of the dental student and—what has been more neglected—more dental education for the medical student. What a disaster occurred in 1910 when Doctor Tyson—the late Professor of Medicine at the University of Pennsylvania—included among the ten questions of the final examination in medicine for the junior class one about the eruption of the temporary teeth! More than fifty per cent did not pass. Fortunately for me I had graduated from the dental school of the University the previous year and this very same question came as a godsend to me—I passed. The joint Medico-Dental Committee of Greater New York has done very commendable work in furthering these studies during the undergraduate work of the two professions and in many other ways. The committee deserves the wholehearted support of organized medicine and dentistry.

However, even this improved education alone will not effect a closer cooperation unless the students will learn to know and understand each other from the very beginning. The two students must meet as much as possible in the laboratories, at conferences, in the operating room, in the wards, and—equally important—socially. After graduation the period of internship will establish closer relations, which will finally ripen into useful cooperation through which, we know the general public will in the end receive the health service it expects and deserves.

It is true that medicodental meetings play an important role in fostering better relations. Also individual efforts by special groups will have to be made. I may mention at this time the New York Institute of Clinical Oral Pathology, whose membership consists of general practitioners and specialists of both professions interested in the clinical aspect of oral pathology. At monthly conferences the presentation of cases and a paper of practical clinical value keep the audience continuously well-informed. Through the medium of a new journal, the *Archives of Clinical Oral Pathology*, such knowledge is disseminated for the benefit of those living at distant parts. Similar efforts should be encouraged.

The cooperation is mostly neglected by the two general practitioners, although it is

most important from the preventive standpoint in that instance. I have shown above that neither practitioner could be sufficiently educated to examine the other's field. Therefore, no examination of a patient can be complete without it. The physician, when seeing his patient the first time will have to refer him to the dentist for the study of the mouth. It is not only the tongue, mucous membranes, and a superficial glance at the teeth and gingivae, but the careful investigation of these structures aided by x-ray pictures of jaws and teeth and the pulp test, etc. that will permit the rendering of an intelligent and comprehensive report to his medical confrere. The dentist is in a similar position. Even if the patient is apparently entirely well, he should inquire as to when he saw his physician last. Assuming he did not visit him for some time, the dentist must insist that he do so, only take care of emergencies and refuse treatment thereafter unless he complies with this request. This means cooperation for the purpose of fostering preventive medicine and dentistry through periodic health examinations. Reporting to each other in every case must be everyday practice.

There is, however, one difficulty. We have good and bad everywhere and also among physicians and dentists. The physician can more easily be looked up, e.g., in the Medical Directory of New York, New Jersey, and Connecticut. Medical school, hospital appointments, society membership give one a fair idea of his standing. The dental profession has not such a book. The smaller membership and therefore finances will not permit their own publication. For some years I have tried to interest a few influential members of the New York State Medical Society for the purpose of joining with the official dental society in the publication of an annual volume for both professions and I hope for its realization. Naturally the information gained by this means is not entirely reliable, for the simple reason that we still have political and social appointments to hospitals. Furthermore, the judgment of the authorities may be poor. For this reason I would suggest consulting local official societies, from whom additional information about the applicant for a hospital position could be secured. No physician or dentist must be appointed unless he is a member of his official society.

I shall take the liberty of adding at this

time a thought regarding essayists for society meetings. Here again—unless the man is really well-known—an invitation should only be extended after a confidential communication with his local official group. This does not, however, guarantee the success of the meeting, but insures the standing of the lecturer.

Previously the fact was mentioned that the two practitioners must assist each other to complete an examination, particularly of a new patient. In addition there are two large groups of diseases, in the study of which neglect of the above is inexcusable—focal infection and nervous disturbances. Although in my opinion oral foci are not as frequently responsible for systemic disturbances as some are attempting to convince us, still our lack of knowledge stimulates our desire to continue our study and leave no stone unturned that may throw additional light on this subject. Teeth, which from the dental standpoint are of no value or a menace, must naturally be removed in the manner indicated by general surgical principles. Our great concern, however, are those members of the masticatory apparatus, which, although their pulps have been removed and their root canals filled in accordance with accepted technic, might still be a focal source and then must be sacrificed, in spite of the fact that only too often this procedure does not in the least affect the general ailment. The physician and dentist must meet here on an equal basis, each state their own case, and decide the course of treatment in accordance with the importance of the facts presented.

Nervous disturbances are another source of deep concern. One of them, trifacial neuralgia, does not belong to this group because its etiology is not known and because as far as is known at present is never relieved by oral operations or dental treatment. As long as there may always be a doubt regarding the diagnosis, the mouth must be well-examined and treated. Facial pains may originate from a dental disturbance and do also require a thorough study of this region.

A large number of the cases belonging to the second group will present themselves in the dental office first and it will be the duty of the dentist to inform the family physician and consult him. Thereafter, they may decide on a specialist and so not only divide the responsibility, but in addition and of greater importance give the patient the bene-

fit of a practitioner equipped with special knowledge and experience.

At present the oral surgeon, who in most instances has devoted some additional time to medical studies, occupies the important position of consultant in his field. The continuously increasing number of medical subjects in the dental curriculum, the students' admission to ward rounds etc. and especially the dental internship, will in the end place the general dental practitioner in a similar position.

While speaking of the oral surgeon and his medical training, I cannot help but think of the opinion so often expressed by well-meaning dentists, that the dental practitioner should have a medical degree. That such a thought must be considered erroneous I hope to have shown sufficiently in a previous paragraph. Let me repeat, however, that a medical degree as such and even including the medical license is meaningless, it is only a minimum requirement of the law, and the studies leading to the degree constitute a foundation only to which, with the aid of an internship, a hospital appointment and a number of years of general practice, enough practical application, knowledge and experience is added, to entitle one to be called and considered a physician. Then you justly also deserve the social position, which goes with it. And the dentist is as important in his field and deserving of the same social standing. It is up to him as well as the physician to acquire this admission not by their degrees, but rather through their professional achievements, purely professional as well as civic.

As matters stand at present the greatest need is more dental information for the medical student and physician. He must discontinue to look upon his cooperator in health service as only a dentist. Important progressive steps have been taken and much has been accomplished by the dental profession, too much to enumerate at this time. I am certain that their research is well-recognized and utilized by medical workers. The opinion might be created that the fault lies with the medical profession alone, which is not the case. The dentists, however, have been concentrating their efforts for a number of years to increase preliminary requirements, adding medical subjects to the curriculum, stressing the importance of dental internship and hospital appointments with the intention to increase their value and

efficiency as guardians of dental health and their ability to cooperate with their medical confreres

The hospital situation must not be overlooked. A dental department must be recognized. The American College of Surgeons cannot be too severely criticized for entirely neglecting this phase. Not a single hospital should be recognized unless it has a dental department. Dentists must be put on every important general committee, not forgetting the medical board. Interference with purely dental affairs shows lack of understanding of its importance and a meddlesome and petty mind. The usual mistake of the medical board or the responsible body is to appoint a specialist—in most cases an oral surgeon—to head this group. It must be a general dental practitioner. Oral Surgery is only one of the subdivisions and a good oral surgeon knows very little about general dentistry, which is most important. On account of the different position this profession occupies, the dental department must be governed by a special board (the dental board) which fully cooperates with the medical board. Arrangements as outlined above will secure mutual understanding and collaboration and give the patients the best care.

Before closing I wish to refer to one other matter which I believe should receive very prompt attention. I am referring to the question of the expert witness. Very recently I expressed my thoughts¹⁶ on this subject and feel, therefore, at liberty to cite verbatim.

Recently I was requested to testify in a malpractice suit and was again astounded at conditions prevailing in regard to the so-called expert witness. Naturally, as far as the witness who testifies under a subpoena is concerned, nothing can be done. Either he knows his work or he does not. An example of the peculiar situations that may arise was shown some time ago, when such a witness maintained that an osteomyelitis of a year and a half standing might have been avoided by placing a drain into the socket of the tooth which had been removed by the defendant, although it is quite evident that this same witness, by performing two radical operations in the course of treatment of the said case of osteomyelitis, was at least contributing to the seriousness of the case, and, in my opinion, should have been the defendant.

In the suit in which I acted as an expert witness for the defendant, the plaintiff's attorney had procured two expert witnesses—one a physician who had been graduated about 1890 and who claimed that he was quite familiar

with conditions about the mouth, having operated on harelip and cleft palate, cysts, etc. This physician expressed an allegedly expert opinion in regard to the extraction of teeth, although he admitted that he had never removed a single tooth. The other witness was a dentist who had been graduated within comparatively recent years, and who, among other peculiar statements, assured the court that he never does anything for a tooth without first taking an x-ray. Such procedure, besides not being the customary accepted practice in this vicinity, may well be doubted as to its veracity.

I am wondering how much good college requirements preliminary to dental education have accomplished, and whether a good character is not of equal importance. I am only too glad to take this opportunity to state that I, for one, feel that in going to court as an expert witness, I do so not for the purpose of testifying for or against the practitioner or patient, but to tell the truth as I see it, to the best of my ability.

We must admit that most suits are instituted against specialists, oral surgeons, exodontists, orthodontists and so on, and that many practitioners enter special practice without sufficient preparation. If they are guilty of malpractice or, as far as that is concerned, no matter who is guilty of malpractice, he cannot expect the cooperation and support of an honest practitioner.

To remedy the conditions discussed above, I recommended some time ago in my address as the incoming president of the First District Dental Society that we "consider the appointment of court experts. Men beyond reproach should be elected or appointed by the organized dental profession and approved by the courts.

The duty of such experts shall be not only to protect professional men against malicious exploitation on the part of patients, but also to act in the interest of patients if such occasions arise. The cooperation of the medical profession to accomplish this end is advisable."

So much for the expert witness.

Let me repeat we need more medical and dental information for the respective students, better acquaintance of the two and better understanding of both interns followed by hearty cooperation of the practitioners. No one can doubt that this will give each steadily increasing knowledge of their fields and improve health service. Unless we violate these principles by public criticism of the practitioners, it will all increase public confidence and result in the gradual disappearance of the many different cults. The dentist will discontinue hunting for a medical degree just for the degree's sake, which in itself has no advantage as far as the improvement of health service is concerned.

With reapproachment and honest understanding, mutual respect will be finally estab-

lished and physician and dentist meet on an equal basis

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D, DR PH, *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

How We Die

He is old, but well built

Begins by having difficulties with one function, then another. Enlargement of the prostate. Inflammation of this gland, then of another part of the body. Disturbances of micturition. Treatment improves the condition, but not fully. From time to time new attacks. Faulty self-treatment brings fever. Weakness ensues. Appetite lags. Loss of weight.

Difficulty to walk. Less outdoors. Pallor, weakness.

As muscle tissue dwindles, any movement becomes painful. Forgotten troubles show up again.

Then there is the mental state. Fear, anxiety. Beginning to see the end. Not enjoying his old time smoking habit and giving it up.

Discontinues reading, both books and newspapers—he, an assiduous reader. Still intelligent, still joking, but less and at longer intervals.

Getting very cranky, more than ever before. Nobody can please him. Ungrateful, exacting, he is torturing his caretakers unnecessarily by constant orders impossible to be fulfilled.

Sleeps badly, by fits, is never rested. His pains in various places become worse—and they are constant. Treatment relieves but little now.

Signs of mental senility, in this case

complicated by symptoms which point to *cerebral arteriosclerosis*. At first there are moments of absent-mindedness, brief, but quite evident. Patient would speak and then, suddenly immobile and with open, staring eyes, would interrupt himself in the middle of a sentence or a smile and would continue the conversation within a second or a few seconds. Later there are real seizures. Loss of consciousness, falling to the floor. Once, when alone in the house, falling on the hot radiator and only a day or two later complaining of a pain in the back. At the examination a large burn of the skin of one side of the dorsal region is seen. Often incoherent speech mixed with words showing that patient is tired of life and calling death as a savior. Nothing epileptoid about these attacks.

At last he is listless, lies in bed motionless, has lost self-control, is unclean and indifferent about it.

When I call he opens his eyes, recognizes me, whines, asks for a change of position. Eats almost nothing.

Ceases to be ashamed. Undressed before a woman nurse, which he never permitted before.

Heart murmur for the first time. Swelling of legs, face, which subsides by treatment. Then definite symptoms of kidney trouble, new to this patient.

A few days later a flicker of life—like a

supreme effort. He wants, of all things, ice-cream, which is given to him. He jokes—with brightness, although finding the words with difficulty.

An hour later again apathetic. Tries to say something, impossible. Half words, confused sentences. Is astonished not to be able to pronounce something familiar. Smiles at his inability. Finds it ridiculous. Somnolence. Hard to arouse him and to have him call me by name, which is only half-spoken, with lips not fully closed and without energy.

Suddenly a movement, rebellion, desire to go out, to walk away, to go back to old life, tumbling out of bed, exhausted.

Replaced, he is evidently tortured by vague unpleasant thoughts. I talk to him. We are alone. The rest of the family are asleep in other rooms. The night is silent.

I speak in a monotonous voice and tell him about the happy future of his children and about many other good things. I give details, all invented. Sometimes his face is a blank, at other times his mouth tries to smile, he opens his eyes with a certain amount of interest and visible gratitude.

Then he falls definitely asleep, and sleeps until he ceases to breathe. His heart stops, his pupils fail to react. Life ebbs, leaks away.

Ideas, associations of ideas, fine threads of ideas, all have ceased to exist. A moment ago they were here, no matter how feeble, now they are not, as if they had never been. Previously, I could wake them, at least partly. Now, impossible. All he has learned in a long lifetime, all has perished in a second with him.

The end

He Is in the Market

He was very tall, very slim and very pale. His eyes were set deep in the orbits and his frontal bones, covered with a glistening white skin without wrinkles and bald to the top of the parietals, looked like portions of a well prepared skull for anatomical study. Before he began to speak I was wondering how a skeletal individual of this sort can move and whether he was really going to open his mouth.

"I have stomach trouble," he said, "but today I am not coming for that. I want to ask you a favor."

I at once took out my pocketbook. I was used to that. In spite of my own poverty and also in spite of my adverse opinion about charity I rarely turned anyone away.

But he stopped me.

"No, it is not that. I cannot accept. I must explain you. You see."

It was evidently difficult for him to talk. He was embarrassed.

"When I die I don't know when that'll be, but when I die I want you understand, my body should not disappear without rendering some service to humanity."

"Well, what can I do?"

"Just send me to a place, to an institution where they can make use of my body when I am dead. Let them pay me now what they wish and I."

"Oh, I see, you do need money after all."

"Of course, I do, but I cannot take it for nothing. When I'll get some money, then I'll come back here and ask you to cure my stomach."

"I am not so sure that I can do it, but you need no money for that. You would not be the only one."

"I know, I know, other fellows have told me what you have done for them free of charge, but I want to pay you and I want no consultation before I am able to pay."

For nothing in the world would he accept my offer.

He had been trained to be proud. He had been in the navy of a great foreign country and had seen the globe. To show me that "it was no baloney," he took out all his papers from his pocket and displayed them on my desk.

A few days later he came again. This time I told him that I had no connection with anybody who might need his remains after his death and that I believed nobody would need them. There was always a sufficient supply and it was improbable that anybody would pay for that.

This enraged him so much, he left muttering gruffly.

But he reappeared within a week, when I succeeded in convincing him that he had exaggerated the value of his body to science. His obsession waned from minute to minute and gave way to reason.

"If that is the case," he meditated aloud, "I might as well try to find a job."

"Of course," I encouraged him, "and until you find one you can get relief."

"None of that for me. I prefer to work, even if it is the heaviest labor and I know I can get it if I want it hard enough."

Medical Preparedness

It is an open secret that compulsory sickness insurance will be on the legislative agendum when Congress resumes regular sessions in January. While leaders of the Administration have not committed themselves on the subject, many significant details point in this direction.

According to a recent article in *Medical Economics*, President Roosevelt has "expressed the conviction that health insurance fitted logically into a well-rounded social security program." It is true that Mr Roosevelt has repeatedly assured the nation that he would make no serious changes in the American system of medical practice without seeking the advice of the medical profession—but what are some of the other facts?

The Social Security Board's medical research committee, which presumably will draft any medicosocial legislation sponsored by the Administration, is not a physician but a lay sociologist, Dr I S Falk, known chiefly for his advocacy of obligatory prepayment for sickness. It does not require much perspicacity to guess that any program of medical care drafted by Dr Falk will embrace compulsory sickness insurance.

Other signs point the same way. When Robert F Wagner, Jr announced his

candidacy for the State Assembly on a platform of compulsory sickness insurance, presumably he was foreshadowing his father's forthcoming course in the Senate at Washington. If for any reason Senator Wagner fails to lead the fight for obligatory sickness insurance, there is Senator J Hamilton Lewis's interest in state medicine to be reckoned with.

It is unlikely that compulsory sickness insurance will be enacted in 1938 or even that the Administration will attempt to make an issue of it. Growing popular anxiety over the unbalanced Federal budget, the effect on business of new payroll taxes, the almost unanimous opposition of the medical profession, will make the politicians walk softly. If the 1938 bill is unsuccessful, however, it will be followed by others at future sessions, with a steady flow of propaganda in the intervals to fool the people into believing a system which has given Europe cheap medical service at high cost will do otherwise here.

There is an "unless" of course—and that "unless" rests with the medical voter. On November fifteenth Congress will meet in special session. Before *your* Congressman and Senators leave for Washington, see that they know you are opposed to compulsory sickness insurance—and why.

A Logical Alliance

The presidential address of Dr A T MacCormack before the American Public Health Association forecasts a closer integration of public health work with private medical practice. When the leader of the country's government-employed physicians decries the socialization of medicine, it is time for welfare agencies and politicians to stop and think.

Dr MacCormack does not minimize the importance of the public health officer by his insistence on the inviolability of private medical practice. Medicine has two aspects, public and private, each of which is best served by respect for the other's role.

Genuine cooperation between these two fields, so essential to the people's best interests, is only possible if neither fears encroachment by the other.

With good will and intellectual integrity such as Dr MacCormack displays, there should be no barriers to close and effective collaboration between the public health officer and the private practitioner.

The respective boundaries of public and private medicine are easily defined. As Dr MacCormack states, the sick individual is usually best treated by his own physician. Mass health measures—sanitation, the control of contagious disease, the analysis of general conditions producing bad health, and organization of efforts to combat them—are the state's responsibility.

Since health conditions and health needs show sharp divergences in different parts of the country, local planning and administration should be stressed. "Remote control" is for the most part impractical in public health. It necessitates too many bureaucratic intermediaries between the central health authority and the public and conduces to an undesirable standardization of health programs. Local health departments, operating in conjunction with the local medical profession, can formulate policies adapted to local needs and carry them out without waste of precious funds for bureaucratic upkeep.

Severe Burns

Branch¹ describes a method for the treatment of extensive burns which has yielded him universally successful results. Following the administration of a sedative, the burned areas are washed with a tincture of soft soap. All blisters are broken and loose skin removed. A one per cent solution of methyl rosaniline is sprayed over the entire area and the burn is then swabbed with a ten per cent solution of silver nitrate. The area is then resprayed with methyl rosaniline on several successive periods during the following hour and one half.

General supportive measures are also included where and when indicated. As soon as the coagulum has formed and when the period of shock and toxemia is over, the patient is permitted to walk.

Under this regime the morbidity was greatly reduced. The duration of pain and shock was shortened and the toxemia did not assume serious proportions. Skin grafting had to be resorted to in only one instance as most of the cases treated showed a sufficient number of epithelial islands when the crust was washed off with brine.

The silver nitrate coagulates the proteins and forms a coagulum which prevents the loss of body fluids. The methyl rosaniline prevents and destroys infection. Second degree burns were completely healed at the end of three weeks and third degree burned areas within a few days longer. The advantage of this method seems to lie in its simplicity and in the reduction of the time the patient must remain in bed.

Climate and Rheumatic Fever

At the present time, considerable attention is being directed toward the climatic treatment of rheumatic fever. This disease, with its attendant damage to the endocardium, has been one of the major problems in medicine. Of particular importance has been the avoidance of re-

currences which are apt to follow the acute upper respiratory infections usually prevalent during the winter months

The transportation of children suffering from rheumatic fever to a subtropical climate where the incidence of sore throats and colds is at a minimum seemed at first to promise much in the way of relief from recurrences. Studies over a period of seven years,¹ however indicate that there is a distinct annual variation in the improvement and protection from recurring attacks. The mild cases of rheumatic fever and rheumatic heart disease showed the most striking results from the change to a warmer climate. Severer cases either failed to respond to the change or were aggravated by an upper respiratory infection.

No definite conclusions can as yet be drawn. Most of the cases treated in this manner have remained in the subtropical climate only during the winter months and were then returned north. Only by transporting a large group of rheumatic fever patients and keeping them in the warmer climate for a period of years can this problem be solved satisfactorily. From an active therapeutic standpoint, caution should be exercised in the recommendation of a change in climate since the economic stress involved may not be compensated by the results obtained.

CURRENT COMMENT

"A DISTINGUISHED ANTHROPOLOGIST pointed out recently the ominous relation between the starvation of European children during the World War and the growing insanity of European political life as those children grew to manhood. The quality of reasonableness, or horse sense, in human beings is not just an accident. You cannot expect reasonableness in a person if he has a history of poor health, malnutrition, physical inferiority, social humiliation, and the kind of economic insecurity in which the individual is helpless in the clutch of events. With negligible exceptions, a mass of people subjected to these circumstances over a long

period will be tinder for the spark of a Hitler who promises to free them from inferiority and humiliation.

"A democratic social order depends on the ability of the common people to think clearly and to use the powers of government to control all dangerous private powers, whether of big business, of organized labor, or of the underworld. To allow a majority of the citizens to be brought up in urban or rural slums, with just grievances against society, with ill-nourished bodies, unnecessary diseases, and frustrated minds, is to wash away the foundations of democracy.

"Through all the generations of waste and lawlessness and corruption, the American dream has never died. Does it sound silly and sentimental now? It had better not, for that dream of a land of freedom to endure forever is all that America means. Without that, we are only one of nature's ghastly jokes."—Excerpts from an article by David Cushman Coyle, to be found in *Harper's* for October.

"SOME MORNING SHORTLY AFTER Congress has reconvened in January, you're going to pick up your paper at breakfast and gulp hard. On page one you'll find the news that a bill has just been introduced in Congress—probably by Senator Robert F. Wagner—providing for a national system of compulsory health insurance.

"A compulsory health insurance bill has long been a-borning. False alarms about it have been sounded on several occasions. This time, however, Washington opinion is virtually unanimous that 1938 will see its introduction in Congress. The bill may not actually be passed next year, but if it isn't, health insurance is certainly likely to become a premier New Deal issue in 1939.

"Given Wagner's sponsorship and the benediction of the White House, this bill will begin its trip through the legislative mill with tremendous advantages in its favor. Health insurance is regarded in Washington as a logical next step in the program of social security. Congress, having forgotten party lines in this respect and approved other social security laws, will scarcely be wholly unresponsive to socialized medicine.

"Physicians with no organized machinery of defense, require a much longer time to coordinate and erect their battlements. Half-baked legislation adversely affecting them can be pushed through Congress while they are still in the processes of analysis—unless they are forewarned sufficiently in advance."—William Alan Richard-

¹ Am Rheumatism Ass'n, 4th Annual Meeting, June 7, 1937

son sounds such a warning in his article in *Medical Economics* of October

'TO HAVE EVERYTHING SAFE is to stop all chance of advance. A 'social security' that claims to make everything safe for all through life would not be social security because it would ruin the chance of advance for society.'—James Truslow Adams asking "Is Security Secure?" in an article in *Barron's Weekly*

"THE INTEREST OF THE PUBLIC and the profession alike are best served by a strict adherence to ethical publicity and recognition of the fact that the physician's sole and proper advertisement is that of a reputation for honest and efficient work, which spreads from one satisfied patient to another"—From the *Bulletin* of the Fulton County (Mo.) Medical Association

"THE WAY OPEN TO EVERY MEDICAL man for recurrent graduate instruction lies in his local and his regional medical society. There he comes into contact with the more active of his colleagues, interchanges ideas with them, hears new methods of work described, and thus is enabled to keep pace with medical progress

"To those who are privileged to attend the meetings of national and international medical associations (general or special) still greater opportunities for growth in general medicine and surgery and in the medical and surgical specialties are afforded."—Dr L. F. Barker, speaking in regard to the Inter-State Post Graduate Medical Assembly, and quoted in the *St. Louis County Medical Society Bulletin* of October 8

"TWO THINGS HAVE TRANSPIRED recently in England that are almost an answer to the claims made for the benefits expected by some propagandists for health insurance. In spite of these claimed long-range advantages of the system in building up national health, last week Sir Kingsly Wood, Minister of Health, made a long speech urging the nation to attain a higher health standard, and mentioned the measures used in Germany and other countries, looking to building up particularly the youth of the country, and mentioned among other things higher wages, better housing, outdoor exercise, and better food. Nothing was said about the health insurance plan! So it is possible that the 'look and a bottle of medicine' has not achieved its purpose. A quarter of a century of state medicine has not,

evidently, improved the health of the population. The root of the matter is that with good food, better wages, better living conditions, the health of the people will be bound to improve, and state medicine is no substitute."—*Pittsburgh Medical Bulletin* of recent date

IN OUR AMERICAN DEMOCRACY, under the political systems now existing—vastly different as they are from the permanent civil service personnel background in Britain's plan of government—we find it impossible to visualize how our politicians would keep their hands off the money's necessary to carry on a governmental health insurance plan—"Politics and Health Insurance Do Not Mix" rightly claims an editorial in October's *California and Western Medicine* from which we have quoted in part.

"WHEN SCIENCE IS DESTROYED by the greed of commerce and egotism of ignorance, what will happen to humanity, bereft of its most understanding friend—ethical medicine? That day is forecast, for the efforts of societies and lay boards are directed everywhere toward the destruction of the professional status and its replacement by an industrial contract."—*The Illinois Medical Journal*, too, editorializes on this vital issue

"DR EDWARD L. BORTZ, A MEMBER of the Lankenau Hospital staff here (Philadelphia, Pa.), addressing members of the women's auxiliary, declared that Senator Wagner of New York planned to introduce a health insurance bill which would 'create a huge political bureaucratic organization'

"Control of American medicine will reside in that organization, not in the hands of the medical profession," he went on. "The quality of care given patients under that organization will be of a very inferior grade, since, instead of calling doctors themselves, they will have to apply first to a political bureau

"If the American people know what a ruse and guise this political bureaucracy will foist on the people, with an increase in taxes and an inferior type of medicine, they won't accept it."—From a report of the Annual Convention of the Medical Society of Pennsylvania, to be found in *The New York Times* of October 6

"THE DEATH RATE OF BETWEEN 40,000,000 and 50,000,000 Americans with incomes of

less than \$1,000 a year from the ten major diseases that cause three out of every four deaths in the United States, is twice that of the rest of the population, Josephine Roche, Assistant Secretary of the Treasury, told the annual convention of the American Public Health Association.

"These figures, revealed for the first time in a Federal survey of 750,000 American families, 3,500,000 individuals, constitute a challenge to Government, public health officials and the medical profession, Miss Roche asserted.

"Governor Lehman, who addressed the general session declared that it was his 'firm conviction that, so far as science and government can make it possible, *an equal opportunity for health is the right of all citizens of the community*, regardless of circumstances, birth, economic conditions, geographical limitations, race, creed, or color'" (Italics ours).

The article in *The New York Times* of October 6, from which we have quoted the above, continued, "The problem of pro-

viding adequate medical care for one-third of the population is becoming so acute, Miss Roche said, that 'no one measuring human needs and denials can doubt' the inevitability of 'concerted public action'.

"In this great democracy with its unsurpassed resources and potentialities for human progress,' she said, 'one third of our people are not going to remain indefinitely ill-fed, ill-housed, ill-clothed and ill-cared for in sickness.

"Organized medicine has admitted the problem and indicated it is receptive to ideas and is willing to cooperate.

"The situation calls for leadership. No one formula or program will probably be found adequate to meet our varied needs, but a composite of many efforts and plans, some in experimental stages, some not yet under way, can and must be found. What group is better fitted to lead and carry through than the public health profession, with its medical personnel and its tradition of fair dealing with the public and with the medical profession alike?"

AUXILIARY LEADERS MEET

Twenty members of the executive board of the Women's Auxiliary to the Medical Society of the State of New York, representing the State officers, standing committee chairmen and county presidents from the twelve organized counties, gathered on Sept. 28-30, at Bayport as guests of Mrs. John L. Bauer, former president of the State Auxiliary. On the evening of the guests arrival they were entertained at an informal dinner followed by a social hour of bridge.

The State president, Mrs. Francis R. Irving of Syracuse, held an executive meeting at which reports of the various county

activities were presented. Outstanding, during the past Summer were the achievements of the Onondaga Auxiliary, which sponsored a maternal welfare campaign, and of Suffolk County Auxiliary, in equipping the infirmary donated by the Suffolk Medical Society to the Boy Scout Camp at Baiting Hollow.

Mrs. Bauer then entertained her guests at a luncheon at the Golden Eagle in Bayport, followed by a drive which included a tour of Cathedral Pines and other parts of Long Island. In the evening the guests assembled at dinner dressed for a party of the 'Gay 90's'.

NATIONAL CANCER COUNCIL NAMED

Approval of the appointment of six men to form the National Advisory Cancer Council is announced by Secretary Morgenthau. The National Cancer Institute, which will be guided by the council, with Dr. Thomas Parran, Surgeon General, ex-officio chairman, will be maintained in the Public Health Service.

Those named to the Advisory Council are

Dr. James Ewing, Director of Cancer Research at the Memorial Hospital in New York City.

Dr. Francis Carter Wood, Director of the

Crocker Institute of Cancer Research in Columbia University.

Dr. C. C. Little of Bar Harbor, Me., head of the Roscoe B. Jackson Memorial Laboratory.

Dr. Arthur H. Compton, Professor of Physics at the University of Chicago.

Dr. James B. Conant, president of Harvard University.

Dr. Ludvig Hektoen, head of the Department of Pathology at the University of Chicago.

The Cancer Institute will be built at Bethesda, Md., on a site given by Mrs. Luke Wilson and her son.

Public Health News

Public Health Aspects of Heart Disease

A disease is a public health problem when it is either a menace or burden to the community. Judged by these standards, heart disease comes within this category. Certain of its causes such as syphilis, rheumatic infection, diphtheria and scarlet fever are in varying degrees communicable. The economic loss it entails has never been calculated, the suffering it causes is incalculable.

Heart disease differs from other public health problems. Unlike tuberculosis, typhoid fever and other infectious diseases it is a generic term covering a group of widely unrelated conditions due to congenital, infectious, metabolic, other or undetermined causes. As in the proper clinical management, efforts in the direction of prevention are dependent on the etiologic viewpoint.

The statement that heart disease is the leading cause of death is household knowledge. In fact, too much emphasis has been placed upon it. Over forty per cent of deaths from heart disease in the United States occur in persons past seventy years. While there has been an aging of the population on account of reducing deaths from infectious diseases, the span of life has not been increased. Despite the optimistic predictions of food faddists, Sunday supplement endocrinologists, and other enthusiasts a material increase in the human life span is unlikely. As a result of saving life in the earlier decades, more deaths from heart disease are inevitable.

While heart disease is a public health problem, the prevention and postponement of its more serious consequences are not as a rule amenable to methods of administrative control. The clinician and not the public health official bears the brunt of the attack. Their cooperation is essential, as witnessed in the current campaign against syphilis. The clinician who prevents cardiac patients from occupying hospital beds at public expense conserves the public funds. Health authorities should take keener interest in heart clinics, undertake studies on the mass effects of heart disease, and encourage research, especially that relating to its etiology.

Morbidity Estimates of heart disease morbidity vary considerably, dependent on whether all patients with cardiac defects are

included, or only those persons with clinical manifestations. Emerson estimated that in 1931 there were between 2,330,397 and 3,665,062 persons in the United States with some form of heart disease, or 19 to 29 per cent of the population. The Hagerstown survey revealed an annual morbidity rate for cardiovascular diseases of 18.3 per 1,000. School surveys range from 0.5 to 4.0 per cent, the consensus being about 1.0 per cent. During the World War twenty-six drafftees per 1,000 were rejected for heart disease. Approximately 2.0 per cent of applicants for life insurance fail to pass on account of this cause.

Mortality There has been an almost constant increase in the death rate from heart disease over a number of years. In the decade between 1920 and 1930 it rose from 159 to 214 per 100,000. In 1935 the rate was 224 per 100,000. It is higher among males than females and among white persons than Negroes, except in the age groups above seventy-five years. It accounts for about twenty per cent of the total mortality.

The situation is not as bad as might be supposed. A substantial reduction has been shown in persons under about forty years in independent studies by Cohn and by Armstrong and Dublin. The experience of the industrial department of the Metropolitan Life Insurance Company indicates that there has been no increase in heart disease mortality. Bolduan & Bolduan point out that its increase in New York City is largely fictitious when considered in conjunction with cerebral hemorrhage, nephritis, senility, and arteriosclerosis.

The writer found that twenty per cent of deaths in hospitals in a large city recorded by the office of vital statistics as heart disease were due to other causes. On the other hand only sixty-two per cent of deaths actually due to heart disease were so recorded, due largely to the failure to tabulate deaths as heart disease when reported on the basis of etiology.

Economic Losses According to the Committee on the Costs of Medical Care, heart disease is the ninth most expensive illness. The average professional charge per case per year was \$49.56. It accounted for 2.5 per cent of the total charges. It is estimated that it costs over \$60,000,000 annually for medical care including physicians' fees, nursing, drugs, and hospitalization.

Bigelow and Lombard estimated that in Massachusetts in 1931 there were 84,000 persons over forty years of age with heart disease, 2,605 of whom were totally disabled. Including the partially disabled 5,377 years were lost annually amounting to \$6,452,000 in wages. At this rate heart disease costs the United States about \$250,000,000 a year in lost wages, taking into consideration that approximately twenty per cent occur before forty years of age.

Not all types have an equal public health significance. The incidence, age distribution, factor of infection, chronicity and other factors require consideration. Some kinds of heart disease are at present preventable, some potentially preventable, while among others an increase can be expected.

Congenital Malformations Account for less than two per cent of heart disease. Frequently associated with other congenital deformities. Not regarded as an important public health problem. No method of prevention.

Diphtheria Results in less than one per cent of heart disease. With active immunization, early diagnosis, and proper treatment, this should cease to be a problem.

Rheumatic Infection Due to its prevalence, age distribution, extreme chronicity, influence on industry and the home, rejections for military service and relatively early ages of death, rheumatic heart disease is an extremely important public health problem. It results in fifteen to forty per cent of heart disease, depending on the locality. The average age at death is about thirty years. It causes at least 40,000 deaths in the United States annually. Paul estimates there are 840,000 cases.

The incidence of multiple cases in a family, occasional outbreaks in institutions, recurrences in cardiac hospitals and certain clinical features point to an infective background. Apparently it is somewhat less common than a generation ago. It is less frequent, but by no means rare, among the better-to-do than the underprivileged. To a large extent it is a product of industrialized urbanization. It seems to be distinctly less common in the South.

The etiology is unknown. Even though the causative micro-organism were discovered, it is doubtful if active immunity could be developed. For the time being, prevention is limited to the proper management of early cases and better child care. These are largely dependent on raising the general standard of living. The public should be educated to the potential seriousness of muscle or joint pains in children. School health examinations should be better utilized for discovering early cases. Sending

children to warm climates is helpful in selected cases, but is hard to visualize on a large scale.

Scarlet Fever This occasionally results in heart disease usually indistinguishable from rheumatic heart disease. It may reactivate rheumatic infection. A better method of active immunization against scarlet fever is needed.

Subacute Bacterial Endocarditis As this is usually superimposed on rheumatic lesions, prevention is in a measure dependent on reduction of rheumatic heart disease.

Thyroid Disease Accounts for less than five per cent of heart disease. With improvement and more widespread use of diagnostic facilities and greater alertness for masked forms, reduction in heart disease associated with hyperthyroidism or myxedema is confidently expected.

Syphilis Results in five to ten per cent of heart disease. Among Negro males it accounts for about twenty per cent. Disability and death occur mostly in the forty to sixty year period.

Its prevention depends upon early and adequate treatment. Progress has been made in the Scandinavian countries, Great Britain and New England. The U S Public Health Service is sponsoring a syphilis control program. *Hospitals and clinics can assist by recording the present incidence of cardio-vascular syphilis as a base line to determine future improvement.*

Arteriosclerosis and Hypertension Three factors play a role in this rather heterogeneous group—arterial hypertension, coronary arteriosclerosis and generalized vascular sclerosis. Altogether it is responsible for about sixty per cent of heart disease. This group has a public health significance insofar as it results in disability and death before completion of the normal life span. Many deaths occur at very advanced ages. Here heart disease is the clinical expression of a general involution.

Coronary arteriosclerosis and arterial hypertension in middle life constitute an important and probably increasing problem. The average age at death from coronary thrombosis is about sixty years. It appears to be more frequent among business and professional groups than wage earners. It is more frequent among males than females, Jews than Gentiles, and white persons than Negroes. It is a sad commentary that many useful citizens die prematurely from overwork while others remain unemployed.

The problem of arterial hypertension is a challenge to medical research. Fahr estimates that 140,000 persons in the United States die annually from essential hyperten-

sion, about 70,000 from heart disease. Unlike coronary thrombosis or angina pectoris, hypertension is extremely common in the Negro race in which it develops earlier, is

accompanied by a more fulminating hypertension, and results in death about ten years sooner than among white persons.

O F HADLEY, M D, Philadelphia, Pa

Recent Tuberculosis Figures

The steady decline in tuberculosis mortality since 1900 is the result of a variety of cooperative attacks on the disease. The objective of the National Tuberculosis Association has been to coordinate all these forces and to focus them on the prevention of the disease. Its statistical studies have proved an invaluable guide in determining effective procedure. The cause of the present lag in the decline of the mortality rate can only be discovered through such studies.

The decline in the death rate from tuberculosis from 200 per 100,000 in 1900 to 53 per 100,000 in 1935 indicates a public health achievement with which the people of this country should be fully acquainted. At the same time it should be pointed out to them that there are still 70,000 deaths from this disease annually, that it is the leading cause of death between the ages of fifteen and forty-five, economically and biologically the most productive years of life, and that tuberculosis is an infectious, and therefore a preventable, disease. With these facts clearly in mind the public will not rest content with what has been accomplished. A death rate of fifty provides no final objective. Why not forty, or thirty, or twenty, or, even better, complete eradication of the disease? There is no reason to believe that these ends are unattainable, but this will depend on the intensification of the present methods of control.

While stressing the gravity of high mortality among young people the fact must be faced that old age, too, makes its serious contribution. For instance, the death rate for seventy-five years and over was 106 per hundred thousand in 1934, while that for the group twenty-five to thirty-four was only seventy-nine. In other words, for every thousand old people there are more deaths from tuberculosis than in any thousand young people. Consider the menace of these old chronic cases, living often as they do as unrecognized spreaders of infection in the families of their children and grandchildren. An x-ray study of this group might yield productive leads in a preventive campaign.

Again at the other end of life's span we still face a shocking tuberculosis death rate among infants under one year of age, nearly forty per cent of the deaths being from tuberculous meningitis. Here is ample evidence of poor work in the field of breaking contacts.

Ten years or more ago statistical studies

brought out the fact that the death rate from tuberculosis among young women was well over fifty per cent higher than that among young men. There is evidence that the wide publicity and alarm created by this discovery has had its effect for at the moment there is a definite indication that the existing ratio to the disadvantage of the young women is distinctly less. One might interpret this as statistical proof of the value of publicity in health education.

In a recent study of death rates by occupation, the employed men were divided into groups according to social and economic status. The figures show that for the highest economic group, including lawyers, physicians, surgeons, etc., the death rate from tuberculosis was only 26.2, while the rate considerably increased through the other groups, such as clerks, agricultural workers, reaching the very high figure of 184.9 for the unskilled group. Also, the same study showed that while the tuberculosis death rate in the general population was 71 per 100,000 in 1930, the tuberculosis rate for men fifteen to sixty-four years of age gainfully employed was 87 per 100,000, being twenty-three per cent higher than the average. All these facts point to the necessity for some strenuous efforts to be put into the field of industry.

While the tuberculosis rate among the colored is three and one-half times that of the whites, their rate likewise is declining, dropping sixty-five per cent from 1910 to 1934. The white rate in the same period declined seventy per cent. We have only begun to supply any kind of special sanatorium or clinic care for Negroes. As they constitute eleven per cent of our United States population, it is vital to control the high rate among them if we hope to eliminate tuberculosis.

With the general decline in the tuberculosis rate there have been corresponding declines at all ages and in both sexes. The declines, however, have not been uniform. In childhood (up to 15 years of age) have

occurred the greatest decreases, while the rates for the middle-aged group and the aged have not declined as fast. The rate for young men has declined faster than that for young women.

Of equal interest with the statistical study of mortality rates is that of the declining rate of morbidity from tuberculosis. Many years ago von Pirquet, in Vienna, and more recently Hetherington, in Philadelphia, reported seventy to ninety per cent of infection with tuberculosis among the general population. While true for the situation in Vienna at the time of von Pirquet's report and of a group in Philadelphia living under unfavorable conditions, the figures do not represent truly the general infection rate for the United States today. The MA-100 study carried out by the National Tuberculosis Association from 1932 to 1934 included 12,000 individuals in widely scattered urban and rural areas and, covering ages from one to twenty and over, gave an average twenty-six per cent of infected persons in the population studied. The range was from nineteen per cent of those under one year of age to forty-six per cent of those aged twenty and over. Further tests are under way with PPD and the tabulation of 40,000 cases similarly studied will soon be available for comparison with the MA-100 list. It is doubtful that the results will show an adult rate of infection running over fifty per cent.

A striking statistical study in the tuberculous field is the increase of beds for the tuberculous. In the *Journal of the American Medical Association* for December 7, 1935, is the report of a sanatorium survey which gives the number of beds for the tuberculous as 95,198. Of these nearly 15,000, or fifteen per cent, were located in general hospitals, an interesting observation and one that may have its ultimate influence on sanatoria used exclusively for tuberculous patients.

A further trend in this direction is evidenced in a study made in 1935 which showed that in the state of Wisconsin eighteen per cent of the tuberculosis deaths occurred in general hospitals. Undoubtedly the modern methods of surgical treatment of the tuberculous have brought about this change.

In 1933, Dr. Bruce Douglas, chairman of the Committee on Treatment, reported that of 29,211 patients in 112 institutions of 100 or more beds, thirty-nine per cent had received or were receiving some form of collapse therapy. In six institutions over seventy per cent of the patients had been or were being treated by collapse therapy. According to the study of the American Medical Association, a total of 406 sanatoria and 101 of the principal tuberculosis departments of general hospitals are equipped with facilities for pneumothorax and administer over 500,000 treatments yearly.

Statistics regarding the staggering investments in institutions for the care of the tuberculous and the annual cost of their maintenance present cogent arguments for intensifying the preventive aspects of tuberculosis work. The valuation of the institutions themselves runs over \$329,000,000 and the annual cost of maintaining them amounts to \$76,000,000.

Of all statistical studies into the mortality and morbidity from tuberculosis none is more interesting than that of geographical distribution. Granting the well-known fact that urban rates exceed those of rural areas it is still somewhat of a mystery why some states show such an amazingly low mortality. For instance, Wyoming has the lowest rate for 1934, a mere 18.5 per 100,000, Nebraska and Utah have rates of 21 plus, Iowa and North Dakota, rates of 25. All in all there were 13 states with tuberculosis rates less than 40 per 100,000 in 1934 including Oregon, Maine, Minnesota, and New Hampshire.

Dr. Dauer, of Tulane University, by constructing a map showing death rates from tuberculosis by counties, has demonstrated a series of endemic areas of tuberculosis, which follow no artificial state boundary lines. Dr. Dauer is extending this study to cover the whole United States and the results of it will be of extreme interest.

It may be advisable to put intensive efforts on such highly infected areas rather than to attempt to cover whole states in which large areas are almost devoid of tuberculosis.

A Resume of Recent Tuberculosis Figures, Jessamine S. Whitney, Statistician National Tuberculosis Association, 50 West 50th Street New York, N. Y.

On October 1, the State of New York was officially designated by the U. S. Department of Agriculture as a modified accredited area, indicating its practical freedom from tuberculosis of cattle. New York thus becomes the forty-sixth State in which all counties are in the modified accredited status, indicating that bovine

tuberculosis has been reduced to less than one-half of one per cent as shown by the tuberculin test. In continental United States there are now no counties east of South Dakota that have not been designated as modified accredited areas, and only one other State, California, in which there are any nonaccredited counties.

Medical News

Broome County

THE REGULAR MEETING of the Broome County Medical Society was held on Oct 12. Among the interesting topics discussed were the pneumonia control program, the compensation fee schedule, and the organization of a speakers' bureau.

A special meeting was held on Oct 20. The speaker was Dr B R Kirklin, Professor of Radiology in the University of Minnesota Graduate School of Medicine, Director of the Division of Radiology of the Mayo Foundation, Chief of the Section in Radiology in the Mayo Clinic, who spoke on "Diseases of the Intestinal Tract". Officers will be chosen at the December meeting.

The Comitia Minora has made a recommendation that the meeting dates should not be changed "for usually insufficient reasons," nor should the meetings be merged with other organizations, or outside speakers be imported "to the almost exclusion of its own members," for "the impression is gathered by outsiders that there is no local talent, and none developing. The Committee does not believe this to be true."

Columbia County

THE COLUMBIA COUNTY MEDICAL SOCIETY met in annual session on Oct 5 at the Hudson City Hospital with a business session in the morning and scientific session in the afternoon. Dr Hugh G Henry, retiring president, presided at the business meeting and gave a paper on "Fever Therapy" at the scientific session.

Officers chosen were President—Dr R L Bowerhan, Vice-President—Dr L J Early, Secretary—Dr Henry C Galster, (re-elected). The censors were all re-elected and Dr Louis Van Hoesen added to the group. Committees will be appointed later by the new president.

The physicians were entertained at luncheon at noon by the board of trustees of the Hudson City Hospital.

Herkimer County

DR. J F GALLO spoke at the regular meeting of the County Medical Society on Oct 12 in the Mohawk Valley Country club. Dr Gallo's subject was "Injuries to Fetus at Birth." Dr G A. Burgin spoke on "Subdiaphragmatic Abscess."

Kings County

THE SECTION OF THE MEDICAL SOCIETY of the County of Kings on Laryngology, Rhinology, and Otology is arranging a comprehensive program for the November 10 meeting. The evening will be devoted to the "Problems of the Hard of Hearing". Prominent speakers will present the subject from practical, educational and legislative standpoints.

This meeting will lay the cornerstone for the future activities of the County Medical Society in this important field of public health work. Discussion will center about the needs of the individual with hearing defects and the facilities available to meet these needs.

The medical profession, nurses, teachers, friends, and social workers are cordially invited.

The meeting will be conducted on schedule, promptly at 8 P M in the MacNaughton Auditorium.

Monroe County

SIX HUNDRED ATTENDED a clambake in Webster Presbyterian Church on Sept. 23, the twenty-third annual bake in honor of Dr Alvah P Maine, for more than fifty years Webster's "country doctor." Doctor Maine celebrated his ninety-first birthday the day before. He retired about five years ago.

DR HOMER F SWIFT, DIRECTOR of the hospital of the Rockefeller Institute for Medical Research, New York, spoke on rheumatic fever before the Rochester Academy of Medicine on Oct 7. Doctor Swift was introduced by Dr David B Jewett, vice-president of the academy in absence of Dr Albert D Kaiser, president. Doctor Kaiser is attending sessions of the International Pediatric Society's meeting in Rome, Italy.

Nassau County

RECOMMENDATIONS FOR THE REVISION of medical relief administration in Nassau County were made at the meeting of the County Medical Society in Garden City on Sept. 28. During the scientific session Dr Russell L Cecil of New York hospital gave a paper, illustrated with slides, on "The Serum Treatment of Pneumonia", Dr Edward S Rogers, director of the bureau of pneumonia control of the state health depart-

ment spoke on "The State Campaign Against Pneumonia" and Dr Theodore J Curphey, pathologist at Meadowbrook hospital, on "The Bacteriology of Pneumonia and the Modern Method of Typing"

New York County

DR WILLIAM FREEMAN SNOW, general director of the American Social Hygiene Association, was the guest of honor at a testimonial dinner, attended by more than four hundred persons at the Waldorf-Astoria, on Oct 1

Dr Thomas Parran, surgeon general of the United States Public Health Service, urged the formation of "one strong national, voluntary agency" to carry on the work against syphilis and gonorrhea

The speakers devoted most of their talks to praising the forty years of work in social hygiene conducted by Dr Snow

Major General Merritte W Ireland, former Surgeon General of the United States Army, presided

Other speakers were Dr Wilbur A Sawyer, director of the international health division of the Rockefeller Foundation, Jerome D Greene, secretary of the Corporation of Harvard University, Dr John L Rice New York City Health Commissioner, Sir Arthur Newsholme, British public health authority, Dr Livingston Farrand, president emeritus of Cornell University, and Dr John H Stokes, professor of syphilology at the University of Pennsylvania

Niagara County

DR DESCUM C MCKENNEY was the speaker at the regular meeting of the Medical Society of Niagara county on Oct 12 at the Tuscarora club in Lockport. He spoke on "Rectal emergencies in general practice"

Oneida County

DR LOUIS C KRESS, assistant director of the State Institute for the Study of Malignant Disease, addressed the Medical Society of Oneida County on Oct 12 on "Common Types of Cancer Encountered in Daily Practice." The meeting was held at the Oneida County Hospital, Rome

Onondaga County

THE TOPICS AND SPEAKERS at the meeting of the Onondaga Medical Society on Oct. 5 were "Pneumonia Control," Dr W A Groat, "Syphilis Control," Dr T P Farmer, "Workmen's Compensation Law," Dr L E Sutton, Dr T F Laurie, Dr O W H Mitchell

THE SYRACUSE ACADEMY OF MEDICINE met at the University Club on October 19. The speaker, Dr B R Kirklin, Chief Roentgenologist, Mayo Clinic, Subject "Some of the Clinical Aspects Pertaining to Roentgenology"

THE FIRST FALL MEETING of the Women's Auxiliary to the Onondaga County Medical Society, took place Tuesday night, Oct 5, at the home of Mrs Francis R Irving

There was an interesting program with a paper on "Principles of Home Decoration," by Mrs Edwin Shepard, a book review by Mrs Raymond J Pieri, and piano selections by 13-year-old Ferman McKaig

Ontario County

DR E L STEBBINS addressed the Ontario County Medical Society in Canandaigua, on Oct 12, on "Source, Diagnosis, Clinical Course, and Treatment of Some of the More Frequent Streptococcus Infections Encountered in Medicine"

Orange County

MIDDLETOWN AND ITS HEALTH department were honored in New York City at a banquet session of the National Public Health Association convention, for having achieved first place in national competition with other cities its size for excellence in health and health protection

Dr H J Shelley, city health officer, had been invited to attend the banquet but was unable to appear. Dr Frank W Laidlaw, district health officer, was delegated to represent him and to receive a certificate symbolic of the city's prize rating. Several months ago Middletown received a bronze plaque for its standing

Otsego County

THE SEPTEMBER MEETING of the Otsego County Medical society was held in Coopers-town on September 24. Dr Harold D Harvey, of the Presbyterian Hospital (New York City) spoke on "Early Efforts to Evaluate the Results of Sulfanilamide."

Queens County

THE MONTHLY MEETING of the Woman's Auxiliary to the Medical Society of the County of Queens was held on Sept 28. Mrs John W Mahoney presided

After the reports of the committee chairmen, volunteers were asked to serve for the United Hospital drive. Mrs H P Mencken read the proposed changes in the by-laws of the Constitution. The installation of new officers will take place late in December, Mrs

MEDICAL NEWS

Number 211

Elmer Kleefield, chairman of delegates to the State convention, gave a report. Mrs John W Mahoney read her report of the national convention.

Mrs Harold H Mitchell gave an explanation of the workings of the City Health Department and told about the opening of the new Health Center in Astoria on Oct 15.

A "CIRCUS PLUS" is ANNOUNCED under the auspices of the Queens County Cancer Committee, with variety acts and stars of the stage, screen and radio. It will take place in December, but the Cancer Committee's office is as busy as political headquarters in a heated campaign.

The committee's task includes a house-to-house canvass of the borough—for the sale of tickets. A group of National Youth Administration girls is assisting the regular staff headed by Mrs Walter Kerwin. The committee plans to open branch offices throughout the borough.

This is the first time the committee has undertaken such a big presentation. In the past it has sponsored bazaars and donkey baseball games. But this year's big show, "The Calvacade of Sensations," will be presented at the Jamaica Armory eight times at matinee and evening performances on December 2, 3, 4 and 5. A souvenir journal will be published in connection with the show.

In other years the committee has raised funds through its annual mail appeal. This year it is substituting the circus and stage presentation.

Rensselaer County

JOHN J AHERN, commissioner of county welfare, has asked the help of the Rensselaer County Medical Society in the formulation of "reasonable" regulations for the care of the sick among old age pensioners in the county.

Addressing the society on Oct. 5, at the Health Center, Commissioner Ahern termed the regulations drawn up by federal and state authorities affecting persons receiving old age pensions in need of medical care as "arbitrary."

The regulations have been made entirely by laymen, he said, and are wholly inadequate. Only ten calls by physicians at the homes of the sick are permitted in each case, regardless of how serious it may be. The county official pointed out that in Rensselaer County at least he wanted the regulations to be made more "flexible."

Money is available for whatever medical care the old age pensioners need in the county, he explained. There is a fund-at-

large from which sums may be withdrawn for the purpose.

ACTING ON THE PLEA for cooperation, the society gave the president, Dr Stephen H Curtis, authority to appoint a committee to confer with the county official regarding changes he proposes to make.

Two scientific papers were read, one on "Gall Bladder Disease" by Dr Peter L Harvie, and another on "Jaundice" by Dr Crawford R Green. A discussion of the papers followed with the following doctors taking part: Dr M A DeLuca, Dr John H F Coughlin, Dr Eugene F Connally, Dr Charles F Kivlin, Dr Richard P Doody and Dr David W Houston, jr.

DR. VICTOR C JACOBSEN, practicing physician in Troy for three years, attending physician and pathologist at the Samaritan Hospital and pathologist at the Mary McClellan Hospital, Cambridge, has been named associate professor of medicine at the Albany Medical College. Dr Jacobsen will also be attending physician at Albany Hospital, and will continue his practice in Troy.

Rockland County

THE FIRST MEETING OF the Rockaway Medical Society for the season was held Oct 21 at the Lawrence Country Club. Dr Louis A Sarrow, president. Dr Milton Morris, vice president, Dr Charles Martin treasurer and Dr Alfred Calvelli, secretary, all new officers of the society, were serving for the first time. The speaker was Dr Raphael Lewy, chief of the medical department of the New York State Department of Labor. His topic was "Conceptions of Industrial Surgery."

Schenectady County

A MEETING OF THE WOMEN'S auxiliary of the Schenectady County Medical Society was held on Sept. 28 at the Ellis hospital. Dr Joseph S Lawrence executive secretary of the state medical society spoke on "State Medicine." Mrs Herman W Galster presided.

Seneca County

DR FREDERIC W LESTER, secretary of the Seneca County Medical Society, reports that the regular annual meeting of the Seneca County Society was held at the Willard State Hospital on October 14. Dr W R Holmes, president, called the meeting to order and regular business was discussed. A luncheon was held in the hospital parlors at the invitation of the hospital medical superintendent, Dr Harry J Worthing.

The scientific program included a short

address by Dr. Don M. Griswold, District Health Officer for the new health district comprising the Counties of Ontario, Seneca, and Yates. Dr. Ferdinand J. Schoeneck gave a paper entitled "Disproportion in Obstetrics." Discussors included Dr. Asel J. Bennett.

A paper entitled "Insulin Shock Treatment in Dementia Precox" was given by Dr. Ross E. Herold of the hospital staff. The paper was followed by general discussion and questions regarding the twenty-eight cases now under treatment by this method.

Steuben County

DR. ELLEN SUTTON, a missionary in China, addressed the Hornell Medical and Surgical Association at their regular monthly meeting in the St. James Mercy Hospital, on Oct. 4, on "Medical Conditions in China."

Washington County

DR. SAMUEL J. PASHLEY was elected president of the Medical Society of the County of Washington at the annual meeting held on Oct. 5 in the Hudson Falls court house. He succeeds Dr. John H. Ring.

Other officers elected were *Vice president*, Dr. W. B. Nuzzo, *secretary*, Dr. Denver M. Vickers, *treasurer*, Dr. Charles A. Prescott, *members of the board of censors*, Drs. R. E. LaGrange and Charles H. Tolmes, *chairman of the committee on legislation*, Dr. W. A. Leonard, *chairman of committee on public relations and medical economics*, Dr. Michael A. Rogers, *delegate to the State society*, Dr. Denver M. Vickers.

Wayne County

WAYNE COUNTY PAPERS carried articles in September noting that few physicians in central New York can point to a longer record than Dr. William H. Sweeting, who observed his eighty-sixth birthday on September 22. He has been practicing medicine at Savannah fifty-four years, and has no thought of retiring. Dr. Sweeting began his practice in 1883 and has kept steadily at it since then, scarcely ever taking a vacation. He also has served the village as mayor, and as health officer for many years in both the village and town. Dr. Sweeting is a charter

member and former president of the Wayne County Medical Society.

Westchester County

DR. GEORGE H. RAMSEY, Assistant State Health Commissioner for the last five years, will be the new Westchester County Health Commissioner, and will take up his duties in December. He will succeed Dr. Matthias Nicoll Jr., present head of the county board of health and former State Health Commissioner. Dr. Nicoll reaches the retirement age of seventy next spring.

The county health board, which appointed Dr. Ramsey, also voted approbation of decentralization of the county health organization. If the Board of Supervisors approves, a plan, voted by the Health Board and sanctioned by Dr. Nicoll, would be effected.

Under it the county will be divided into four health areas, each with a district office and a staff of physicians, nurses and sanitation experts.

THE MOUNT VERNON MEDICAL SOCIETY held its "get together meeting" on September 16 at the Swanoy Country Club. About forty members of the Society attended the dinner in the evening and about fifteen played golf during the afternoon. Dr. E. B. Sullivan, who holds the A. M. A. Golf Association championship, won first prize, a gaily colored golfer's umbrella. Dr. Karl Gebhard and Dr. Carl Vrooman won second and third prize respectively, each receiving a half dozen golf balls. The Society enjoyed an excellent dinner.

THE MEDICAL STAFF of Northern Westchester Hospital in Mount Kisco held its annual dinner meeting at the Carmel Country Club, September 22. Dr. E. H. Wilcox was elected president and Dr. Alexander Vanderburgh was elected secretary.

THE WHITE PLAINS MEDICAL SOCIETY held its final golf match of the year at the Gedney Farms Golf Club on September 22.

The Society held its annual dinner at the same Club in the evening following the golf play. About forty members of the Society were present for the dinner.

Dr. H. C. Hancock won low gross in the golf tournament, Dr. Arthur S. Strauss was low net winner, and Dr. R. J. Heffering won the kicker's. Twenty-two members played

One of the exhibits at the San Francisco Fair in 1939 will be a group of animals fed from birth on concentrated food capsules, chemically compounded to give a perfect diet. The thought is that we shall

all be living on a similar capsular intake by 1995.

This dreary prospect may reconcile those of us who have dates for the happy hunting grounds before then.

Hospital News

The Hospital with a Smile

"MY GOD, MAY I WHY DO HOSPITALS have to be so cold?" asked a father whose little daughter had died in a New York state hospital. He had spent ten days in the hospital, yet "not until we were asked permission for an autopsy did any one ever show us, by word or deed, that they understood. No one ever seemed to realize that that little suffering child was mine, that I loved her more than anything in the world, nor that my wife had the heart of a sorrowing mother."

This incident was related by Mr M P Tanner, Assistant Superintendent of the Buffalo General Hospital, in an address on the topic, "Can we Give our Hospitals More Personality?" at the convention of the State Hospital Association in New York City in May. When he sat down, the chairman exclaimed "Congratulations! For twenty years I have listened to papers, and I have yet to remember one more interesting."

Courtesies "involve no expense," remarked Mr Tanner, and they "reap a real harvest in additional good will." Yet he went on to make this rather amazing revelation

In a recent article in a hospital journal the author made the statement that Telephone Company officials upon investigation had learned that hospitals are less receptive to possibilities of building public good will than other organizations. It has been said authoritatively that hospitals do not extend the same courtesy as business houses, department stores, and hotels. What a sweeping indictment! Here we are in charge of the fifth largest industry in the Nation being told that we do not have as much personality in our organization as that place where we buy our electricity or gas, or even a suit of clothes, or the place where we stay overnight when we are one hundred percent normal. We are not dealing with people in the mental state of the thousands that go through the doors of this hotel every day, but with people who are worried and anxious, with people who are undergoing perhaps the most vital experience of their whole lives. Notice the employees in this hotel—they radiate Astor personality, they clearly demonstrate in every step they take and every word they speak that they have had training

operator, for she makes the first impression when the hospital is called on the phone. 'She is the connecting link with the outside world. To thousands who never enter the front door she represents the hospital.' Her training in courtesy and sympathy is of the first importance. Then the elevator operators, hallmen, and all other employees who come in contact with the public, play their part. They must "carry the necessary smile, learn to speak to people, to call them by name if possible, and to act intelligently in emergency." Mr Tanner went on

No, we are not going to forget the Information Desk. Here is stationed the Number One person of the group that meet the public. It has been estimated that as high as forty to fifty percent of the people who enter the front door never speak to another member of the hospital staff—that makes her job a tremendous responsibility.

I like to tell the story of a young lady at a hospital information desk whom I saw a few weeks ago. An elderly lady crossed the lobby, sat down in a chair, and was having considerable difficulty in tying a shoe lace. The information dispenser left her desk in a flash and tied the annoying lace. If you could have seen the pleased look on this visitor's face, you would agree with me that this employee was truly giving the hospital a bit of personality.

A conversation at another information desk intrigued me the other day. The visitor, a middle-aged prosperous-looking lady, inquired, "Could you tell me if Miss Lowell in Ward B is to be operated on today?" The clerk replied, "I shall be glad to find out for you." The necessary 'phoning done, the young lady said to her inquirer, "No, not today, the nurse thought Miss Lowell would go to surgery tomorrow, would you like to go up stairs to see her?" The surprised visitor replied, "Yes, I would but not until I have told you that the reception I have received here this morning is a decided contrast to the one I was subjected to an hour ago in one of the other local hospitals. I was almost insulted in an effort to ascertain my aunt's condition." There is the type of public reception we all desire and my guess is that the young informationist had received some training.

How to Use Baseball and Prize-fights

A "glorious opportunity to spread to every maid and every waitress the story we desire" is afforded by the department head meetings,

A Friend Won by a Shoelace
Take first of all the hospital's telephone

Mr. Tanner believes The *esprit de corps* of the entire hospital staff can be cultivated to a high pitch by the right personal touch. Department heads can easily discover the special interests of the various workers. Thus

If the chef is interested in baseball can it not be arranged for him to attend the opener, and if the painter is a fight addict his foreman can spend a profitable minute or two now and again in discussing with him the relative merits of Joe Louis and Jimmy Braddock, and if you know these interests it is going to help if you, in passing through the kitchen, find out just where the "Yanks" will finish this season. Perhaps the pharmacist is an amateur photographer. Take five minutes to admire his pictures next time you are in and if you could arrange to see the dietitian, whose main hobby is local dramatics, in her next play she would love it. Department heads should learn the joys and sorrows and hardships of their employees and make it their job to display genuine interest in everything from a birthday to a wedding. It is just as important for department head meetings to discuss this type of management as it is to determine the best method of routing linen to the floor and back to the laundry. These people are our foremen, and they should be encouraged to hold conferences with their employees and obtain the results that this contact will make possible. Not long ago while walking in the basement of a hospital I saw a man looking for a certain department. He was espied by a maid who left her work and took the visitor to the proper door, which was infinitely better than attempting to direct him. Upon inquiry I found that even the maids in this hospital had been given

instructions on how to assist the wandering public. It is mighty important for us to train our department chiefs in order that the attitude of the Superintendent's Office permeate every corner of the organization.

Dear Old Joe Public

The Superintendent of Nurses undoubtedly has meetings with the floor and other supervisors every week. The most should also be made of this opportunity because the nurse with her hundreds of daily duties can not be expected to remember that her work also includes, as does every person's in the hospital, this very important duty of making the hospital well thought of by every one who comes inside its doors. Did it ever occur to you that people will talk about your hospital if they know anything about it? Through these nurses we have a chance to educate our public because patients and their families talk to the nurse. How many of your nurses know that the hospital has 365 persons on the payroll, or that there are over 2,600 meals served each day, or that the laundry processes nearly two tons of linen every twenty-four hours, or that between fifty and sixty nurses are graduated from its school annually. Do the members of your staff know that their hospital does each year free work in excess of \$100,000, or that over 50,000 visits are made to the Out Patient Department at a terrific annual cost to the hospital? These are bits of information in which the public will be interested. It does not take Dear old Joe Public long to find out the unpleasant details of hospitals and it is our job to tell him the interesting worth-while facts and give him a chance to readjust his attitude about the one civic enterprise which he would not do without.

Scottish Hospitals and Ours

MARVELING AT THE MODERN equipment of Grasslands Hospital in comparison with hospitals of Scotland, Miss Annie Winifred Connolly of Stevenson, Ayershire, Scotland, praised the American hospitals following a tour through the County Clinic in August as a guest of Welfare Commissioner Hugh F. Graham of Greenburgh.

Miss Connolly is a graduate nurse and is a teacher of nursing in the Junior Instructional School, Motherwell, Scotland.

The visitor was surprised to find the various classes of treatments collected together in one hospital. In Scotland a general hospital is entirely separated from those for infectious diseases. The tuberculosis sanitarium was the most unique department of the hospital that pleased Miss Connolly.

The American sanitariums are modern to the smallest detail, she said. The sunlit wards, the freedom and the educational facilities are wonderful. In Scotland a child under treatment for tuberculosis loses this part of his education, Miss Connolly explained. The freedom allowed both patients and visitors in our hospitals was something new. In Scotland the discipline is quite strict.

In describing the operating room of our great hospitals she said that they are the most efficient that she has ever seen. In Scotland, the room is called the "theatre." It is a common phrase for the nurses to say to the patients, "we are going to the theatre this afternoon," the visitor smiled.

When asked about the comparative cost

of medical attention, Miss Connolly burst forth with a lengthy reply on the expensiveness of our doctors and hospitals.

Visits to doctors, or professors as they are called in her native country cost one dollar for the ordinary consultation, and hospital charges are inexpensive, she said.

Miss Connolly went on to explain why she thought there was such a great difference in charges. In Scotland there is a country-wide feeling that hospitals are in need of charity. This thought is impressed into the children's minds from early stages. Once a year, every student takes part in what is called student's day. They dress up in fancy costumes and solicit funds for the hospitals and sanitariums.

The children are quite persistent in their

efforts and many persons buy Immunity Badges previous to the campaign which shows the solicitors that the person wearing a badge has contributed his share to the fund.

A compulsory charge of one penny is fixed on all salaries and this amount is used for a general hospital fund. The nurse stated that clinics were used by the best of people and not looked upon as a form of charity as it sometimes is accorded in this country.

Women's clubs are constantly campaigning for funds and a radio broadcast is made each week for institutions that are in need of funds. There are just as many cases in the hospitals in her country in proportion to ours, she stated.

Newsy Notes

NEEDLESS AMBULANCE CALLS

JAIL TERMS AWAIT THOSE who make unwarranted ambulance calls. Dr. S. S. Goldwater, New York City Commissioner of Hospitals, has announced.

Summoning an ambulance for a sick dog or cat or when the baby refuses to take its bottle may seem a necessity to some folks, but it's getting to be a "pain in the neck" to hospital officials, says a New York newspaper.

In the future, Dr. Goldwater will check all ambulance calls. Those which prove unnecessary may cause immediate arrest of the persons who sent such calls. James Murray has been assigned by Dr. Goldwater to investigate calls and cooperation of Police Commissioner Valentine has been promised.

The straw that broke the camel's back proved to be in the hands of Edward Beaford, Brooklyn. He was arrested by investigators of the Department of Hospitals after it was found he had sent a call for an ambulance when his cat became ill.

Beaford was found guilty of disorderly conduct and received a two-day sentence in Raymond St. Jail from Magistrate Brill.

Of the 186,660 ambulance calls registered in Brooklyn and Queens last year, Dr. Goldwater says 105,040 were "negligible" and "entirely unnecessary." Most of these cases, he said, could have been handled by any one with an elementary knowledge of the use of a first-aid kit.

It costs the city about \$650,000 annually for ambulance service. Private institutions get about half of this. Dr. Goldwater estimates that each ambulance call costs the city \$2, not to overlook hazards to the driver and interne speeding to the scene.

NURSE SHORTAGE LAID TO LOW PAY

THE IMPENDING SHORTAGE of adequately trained nurses for New York city hospitals, reported by Hospital Commissioner Goldwater, is confirmed by Mrs. Marion Fleming, chairman of the New York Counties Registered Nurses Association.

Until an increased appropriation makes it possible for nurses to live "as other professional women do," Mrs. Fleming declares, there can be no improvement in the situation.

Despite the eight-hour day put into operation officially in July, Mrs. Fleming explains conditions in the municipal institutions have proved so unattractive that a drive sponsored by her organization to divert nurses into those hospitals brought few results. The salary of \$75 a month and maintenance for general duty, she explained, is far less attractive than the remuneration received in the field of public health.

"To meet the eight-hour law," she explained, "it proved necessary to increase the already heavy patient load for each nurse, making a routine of exhausting physical effort for practically every one. The main-

tenance provisions include crowded living conditions in dark, old and uncomfortable rooms, where the nurses are subject to the same rules that govern students

"If they live outside the hospital where they can escape the atmosphere of illness during their off hours, the city allows them only \$30 a month additional, and, in spite of the fact that many prefer it, meals, room rent, carfare and other expenses can hardly be covered adequately on \$105 a month"

HOSPITALS ASSOCIATED WITH the United Hospital Fund have been notified that an appeal has been made to the Board of Estimate for an increase in rates paid by New York City for the care of public charges in voluntary hospitals. The increase would bring the city's 1938 bill on this account to a total of \$8,259,933

The increased rates, if approved, would add \$2,730,411 to the cost of hospital care for public charges, as compared with a total cost of \$5,529,522 in 1936. The committee remarked that the present rates have been in force for many years and were established on a haphazard basis in the first place.

The following increases in daily rates have been suggested: Infants under five years, from \$1.15 to \$3; medical and surgical cases, \$3 to \$4.25; tuberculosis patients, \$1.75 to \$2.25; active cancer patients, \$3 to \$4.25; custodial cancer cases, \$1.75 to \$2; orthopedic treatment for children, \$1.40 to \$2.25; chronic, incurable or infirm, \$1.15 to \$2; special medical and surgical cases, \$3 to \$4.25; maternity cases, \$35 to \$50.

The fund committee has discussed the rise

in rates with individual members of the Board of Estimate. In a communication to member hospitals it suggested that they act at once to urge city officials to increase the budget of the Hospital Department to meet the proposed rates.

HOSPITAL INSURANCE PLANS keep on growing rapidly throughout the state. Hospitals report that the plans are not only helpful in a financial way to both hospital and patient, but they lead to a larger use of the hospitals which is also beneficial all around. President Ernest G. McKay, of the State Hospital Association, noted in his annual report that New York, Rochester and Syracuse report a material increase in membership, Albany, Troy and Schenectady have set up a plan with Albany as headquarters and are making progress, Buffalo and Niagara Falls have combined and their membership has shown a steady growth, Geneva has had a plan in operation for over a year which has been very satisfactory, Utica has started a service organization, Ithaca and Watertown are making arrangements for a similar service and Elmira is very seriously considering the proposition.

THE STATE HOSPITAL ASSOCIATION voted at its convention in May to favor a bill at the next session of the legislature for an "eight out of twelve-hour day" and a forty-hour work week in the hospitals, as opposed to the movement for a work-day of eight consecutive hours.

Improvements

SENECA FALLS IS CONTEMPLATING a new hospital building, erected near the present building at an estimated cost of \$165,000 for the building and required additional equipment. Plans are prepared, and a petition signed by taxpayers will probably result in whole matter being put before taxpayers of the township at the November election. The project is for a three story structure, 152 feet long and forty feet deep with a wing going back from the center, a wing thirty feet wide. The plan calls for building the new structure thirty feet westerly from the present hospital, which would be retained

for supplementary use along with the new building. The present fine equipment of the hospital would be moved to the new hospital and additional beds purchased to bring the normal capacity up to forty-eight patients. The estimate of \$165,000 includes the cost of additional equipment but does not include the cost of additional land.

THE CORNERSTONE OF THE \$600,000 eight-story addition to Israel Zion Hospital, Forty-ninth Street and Tenth Avenue, Brooklyn, was laid on Oct. 10. The new building will

provide 220 beds, increasing the bed capacity to 670. The structure is more than half-completed and should be ready for occupancy early next Summer.

THE NEW YORK CITY BOARD of Estimate has voted more than a million dollars for improvements at Bellevue Hospital.

THE NEW BETH DAVID HOSPITAL, New York City, was dedicated on Oct. 17.

THE CORNERSTONE OF THE NEW St. Francis Hospital at Olean was laid on Oct. 3.

GROUND WAS BROKEN on Sept. 27 for Highland Hospital's new \$200,000 maternity building, the gift of Miss Louie A. Hall. Five months from now will see completion of the new structure, the only separate maternity building in Rochester, and expansion of facilities for other patients and technical department into two floors now occupied by maternity patients. The three-story structure of red brick, harmonizing with existing buildings, will contain forty-six beds, increasing total capacity of the hospital from 185 to 225 beds.

THE HAMILTON AVENUE HOSPITAL in Monticello is being enlarged by the addition of a solarium, roofed by a sun-deck for convalescent patients.

CONTRACTS FOR IMPROVEMENTS to the Knights of Columbus wings at Gabriels sanatorium in the Adirondacks that will cost \$30,000 were let at the annual meeting of the Knights of Columbus New York State hospital committee at the sanatorium. The improvements call for a new x-ray room, operating room, examining room and new modern equipment for each, and the installation of a talking picture projection apparatus and individual radio outlets in each of the unit rooms. The K of C maintains two units containing thirty-three rooms and an infirmary containing forty-four beds. The radio outlets are to be placed in the infirmary building also.

THE SWEDISH HOSPITAL in Brooklyn is planning to raise \$250,000 for the remodeling of the Chatelaine Hotel, Bedford avenue and Dean street, into a model six-story hospital with 125 beds. The purpose is to provide larger quarters than are now available in the present Swedish Hospital, Rogers avenue and Sterling place, which has only sixty-nine beds. This will be abandoned after thirty-three years service.

THE CAMPAIGN TO RAISE \$700,000 for the improvement and enlargement of Ellis Hospital in Schenectady will be made in the latter part of October. The present hospital began its service in 1885 and is badly overcrowded.

AN AGITATION IS UNDER WAY for building a Community Hospital in Keesville.

. . .

A COMPREHENSIVE PLAN for building an addition to the Rome Hospital to eliminate the present over-crowding is under discussion. The plan is to construct a wing to the east of the present structure of at least fifty beds capacity so as to eliminate operation of the Murphy Memorial hospital in the interests of economy and to eliminate over-crowding in the general hospital.

.

INCREASING THE FACILITIES of the Lafayette General hospital in Buffalo to a seventy-five-bed institution, possibly including a children's ward, is contemplated under an extensive remodeling program recently put under way. Plans call for construction of a new front in Lafayette avenue and extension of the hospital building outward, setting up of a completely new x-ray department, addition of more rooms on each floor of the institution, addition of eight or ten beds, and establishment of an enlarged emergency ward.

THE POLISH MEDICAL AND Dental Association of Buffalo is considering a movement to build a new hospital for the East Side, to care especially for the people of Polish origin.

LORENZ J. BROSNAN, ESQ.

Counsel Medical Society of the State of New York

Hospital's Suit to Recover for Physician's Services

An interesting situation was presented a short time ago in one of our trial Courts, when a hospital sought to enforce the payment of a bill for services rendered to a patient which included professional services rendered by two different physicians*.

The plaintiff in the action was the D. Sanitarium which was conducted as a private or proprietary hospital as distinguished from a public or charitable hospital. The defendant was the husband of a patient who had been attended at the hospital during her last illness, and had died there. While she was a patient she authorized and received certain treatment, including an operation, at the hands of two doctors. One of them was a staff physician and the other was a surgeon not a member of the staff.

The action was brought against the husband to recover approximately \$100 for hospital services, \$225 for medical and surgical services, and \$35 for the services of a nurse. When the case came on for disposition there was no real dispute before the Court as to whether or not the sum demanded as the value of the services was fair and reasonable. The actual question for determination was whether the hospital corporation had the right to recover for the physicians' and nurse's services.

With regard to the amount of the demand which represented the services of the nurse the Court ruled that there was no reason shown why the plaintiff might not properly charge for her services. The testimony in the case indicated that the nurse on the case was one of the regular staff of nurses regularly employed by the hospital and under the direction of the administrative staff of the hospital.

The matter of physicians' fees was challenged on two grounds. *first*, it was argued that an operation does not come under the classification of necessities to render a husband liable, *second*, that without a legal assignment by a physician of his claim for professional services, a hospital has no legal right to sue therefor.

The first problem was disposed of readily by the Court with the ruling that medical

services including operations are in legal contemplation necessities and have been for many years so regarded. In support of that proposition were cited certain cases, one of which was decided as far back as the year 1610.

In ruling that the hospital did not have the right to recover for the doctors' fees the Court said in his opinion:

Although a hospital has been said to practice medicine through the agency of physicians and surgeons, a comprehensive survey of the relationship existing between hospital, physician and patient compels me to adopt the view that a hospital, rather than practicing medicine *per se*, is a place where medicine is practiced by physicians. In *Matter of Bernstein v Beth Israel Hospital* (236 N. Y. 268, 270) it is there stated: "Such a hospital undertakes, not to heal or attempt to heal through the agency of others, but merely to supply others who will heal or attempt to heal on their own responsibility."

The description is as apt in its application to private as to public hospitals.

The cases, therefore, relegate a hospital to the role of a specialized hotel where the sick or infirm in body or mind may be treated by physicians expressly or impliedly employed by them.

Most persuasive, however, is the case of *Matter of Agnew* (132 Misc. 466, 471). There it was held that physicians could recover for surgical services performed in a hospital for a patient who had concealed the fact that he was financially able to pay. The court pointed out that the physicians were "the ones who conferred the benefit" and that they, therefore, and not the hospital, had the better right to reimbursement.

In the instant case there exists no impediment to a suit for services rendered by the physicians who treated the defendant's wife. To allow recovery for medical services in this action would quite conceivably lay the foundation for two recoveries for the same acts. The claim for physicians' services, therefore, must be dismissed without prejudice.

Judgment was directed in favor of the hospital for the amount of hospital and nursing services only.

Plastic Surgery of Nose

A young woman consulted a physician, who specialized in plastic surgery, with respect to complaints that her nose was long,

* *D. Sanitarium v. Blair*, 161 Misc. 716

MEDICOLEGAL

Number 211

humped, and caused her embarrassment. The doctor undertook to perform a plastic operation upon her nose for the purpose of attempting to improve its appearance. She entered a sanitarium and the operation was performed under a local anesthesia.

The doctor removed the bony and cartilaginous hump and narrowed the wide bony bridge, using a procedure which required no external incisions. The patient remained at the hospital two days and thereafter went to her dressings to the office of the surgeon. At one time during the period of aftercare the patient complained of a thick spot of nasal skin on the midline about the size of a pimple. The doctor suggested that it might be excised, but the said procedure was never followed since the patient demanded that the work be done in his office and he refused to do the same except at a hospital.

Some time later a malpractice action was brought against the plastic surgeon, in which the claim was made that he had negligently operated upon her with the result that a scar was left on her nose, that her breathing facilities were impaired and that she had from time to time had suffered some impairment of hearing. About three years after the operation and shortly before the case was to be reached for trial, a physical examination was made of the plaintiff on behalf of the defendant. Said examination showed that the surgery had been well-performed and was successful. A comparison of the plaintiff's appearance at the time with photographs taken before the operation showed that unquestionably from a cosmetic viewpoint the patient had benefitted considerably from the operation. The examining doctor found ample breathing space inside the nose of the plaintiff and found one very small thickened area of skin above the tip of the nose, which was of trivial importance.

After the said examination was made, the attorneys for the plaintiff attempted to prevail upon the defendant's counsel to make some sort of offer of settlement, and when no such offer was forthcoming, the case was discontinued.

Treatment of Lichen Planus

A young woman, twenty-eight years of age, consulted a physician who specialized in dermatology, with respect to complaints

of a skin eruption which had been troubling her for about a month.

The doctor was informed that the eruption began on the right wrist and spread rapidly over her arms, elbows, back, and genitalia with severe itching. Examination led to a diagnosis of Lichen Planus. The doctor instituted treatment for the condition consisting of subcutaneous injections of sodium cacodylate and intramuscular injections of bismuth salicylate. These injections were continued at weekly intervals over a period of about eleven weeks. On certain occasions, fractional dosages of x-ray were administered to the most severe areas—the arms, elbows, and back. During the latter part of the said period of treatment, the patient's condition had apparently improved, but at the end of that period she complained of itching of her external genitals. Thereafter she returned to the doctor with additional complaints of an aggravation of a condition. She then showed evidence of a general dermatitis, which was diagnosed tentatively as a mild arsenical dermatitis.

Sodium thiosulphate was prescribed instead of subsiding in a few days, the dermatitis became severe involving the entire skin surface. As soon as the doctor had ascertained that a complicated dermatitis was developing, he stopped the arsenical medications, which he had been administering. The doctor continued to care for the patient after the condition of dermatitis had become severe and her condition did not begin to improve for a period of about six weeks. During that time she developed many boils from a secondary infection in the groin, genitalia, axillae, and neck. Finally her condition began to clear up and at that time the patient consulted other doctors who took over the care of her case.

The patient instituted a malpractice action charging the dermatologist with malpractice in administering to her excessive dosages of an arsenical preparation, causing her to suffer from a general arsenical poisoning.

The case came on for trial before a judge and jury and the plaintiff gave testimony concerning a long history of pain and suffering. However, she failed to establish, by competent medical testimony that the treatments administered to her by the defendant physician were improper for the condition from which she was suffering at the time. Consequently, at the close of the plaintiff's testimony, the Court dismissed the complaint.

The widespread epidemic of cholera in China is not likely to reach our shores, according to our Public Health Service, as

cholera shows itself in five days, or less time than it takes to come from China, and all cases can be quarantined.

Across the Desk

Don't Despair of the Human Race

OUR CIVILIZATION IS CRUMBLING, according to a distinguished observer whose views must be treated with respect. He is Dr Alexis Carrel, surgeon and Nobel Prize winner, and he delivered this somber verdict on the sons of Adam a few days ago in an address at the 150th anniversary of the Dartmouth chapter of Phi Beta Kappa. "The civilized races," he declared, as reported in press dispatches, "seem to be losing the courage to live. In almost every country the reproduction of the more gifted individuals is decreasing. This phenomenon is of ominous significance. Did it not herald the crumbling of the great civilizations of the past?"

True, we have marvelous machines and devices to surround us with every comfort and luxury, and we are conquering the scourges of disease in a miraculous way, but, asks Dr Carrel, "are health and comfort of any value if we become mentally and spiritually worthless? Those who have given their lives to the search for the prevention and cure of disease," he adds, "are keenly disappointed in observing that their efforts have resulted in a large number of healthy defectives, healthy lunatics, and healthy criminals. And in no progress of man."

To Mold Man Nearer to the Heart's Desire

To remedy this desperate condition of things Dr Carrel would set up "Institute of Psychobiology," where "spiritual as well as material values would be studied." Our learned specialists are confined too much to their own little corners of human knowledge to see man as a whole. Their minds "will have to be organized into a center of synthetic thought, a focus of collective investigation of human problems—in fact, into an institute for the construction of the civilized."

"As far as I am concerned," Dr Carrel concluded, "I intend to devote the rest of my life to the problem of developing man in his organic and spiritual entirety. For the quality of life is more important than

life itself. We must now use theoretical and applied science, not for the satisfaction of curiosity, but for the betterment of the self and for the construction of truly civilized man."

Mountain Views are Deceptive

Dr Alexis Carrel, of course, is a scientist of the highest eminence and distinction, and, when he speaks, we must all listen. But may it not be respectfully suggested that his very position on the mountain peaks causes him to see the rest of us in a more or less distorted perspective? Genius is ever lonely. If mountains could speak, would not Gaurisankar and Kanchanjanga declare that the rest of the earth was in a low state? Our big world seems different to every observer. In the old story, to one blind man the elephant felt like a tree, to another, like a snake, and to the third, like a rope, as they grasped its leg, its trunk, and its tail. Dr Carrel looks out upon mankind and is in despair. Robert Louis Stevenson, dying by inches, said "The world is so full of a number of things, I am sure we should all be as happy as kings." It all depends upon the point of view.

What is true from Dr Carrel's viewpoint may be untrue from another viewpoint. From his lofty station we may seem to be struggling blindly through the fens, but those in the thick of it may see that we are climbing, climbing, up and up and up, slowly perhaps, stumbling and falling here and there, but all the time gaining firmer footholds, a little higher and a little higher, on our way to levels never before attained by man.

The key to solve the discrepancy between Dr Carrel's philosophy of despair and the perhaps childish hope of the rest of us that we are making some progress may be found in his statement that "in almost every country the reproduction of the more gifted individuals is decreasing," a fact that he believes "of ominous significance." What we need, as he sees it, are "minds endowed with universalistic tendencies," for these "alone have the power to solve the problems of modern society." In short, we need great

ACROSS THE DESK

November 1, 1937]

genuses whose minds can grasp the intellectual and spiritual problems of the human race in their entirety. It is said that Lord Bacon knew everything there was to know in his day. Leonardo da Vinci was at the same time a painter, sculptor, and architect. He was versed in anatomy, astronomy, botany, mathematics, engineering, and music. He painted the "Last Supper" and, it is said, invented the wheelbarrow. He anticipated the discoveries of Galileo, Kepler, and Copernicus. There was, indeed, a "universal mind." We have too few, if, in fact, any such minds today. Dr. Carrel is certainly right about that.

An Epochal Experiment

But we are living in a different world now. If we are to judge the human race, let us look at the race, and not at the few outstanding individuals. The civilization of da Vinci and Lord Bacon is gone forever, and we shall make a huge mistake if we try to judge the twentieth century by the sixteenth. Four hundred years ago great geniuses towered to the stars. Today, instead, we are trying to lift the whole people to higher levels. Which is better? To ask the question is to answer it. If what we want is a higher civilization, then the elevation of the entire population to new plateaus of mind and spirit is the most promising achievement in history.

We are putting democracy to the test. Students of history say that genius flourishes best under regimes of monarchy and tyranny, when brilliant minds are given royal protection and favor. We are trying a different plan. We are educating everybody. Out of a total population of 130,000,000 around 30,000,000 are in our public and private schools and 1,000,000 are in our colleges and universities, learning things that Lord Bacon and da Vinci never dreamed of.

It is common for us to think of Great Britain as the land of culture, but, if we look more closely at British society, we find that its culture is the culture of a class. Great Britain has a population of some 45,-

000,000, or about a third of ours, but has only 6,000,000 pupils in its common schools, or about one-fifth of ours, and where we have 1,000,000 college and university students, Britain has only 55,000. America is trying a colossal experiment, never before attempted on this planet. We are trying to bring culture into every town and city, into every village and hamlet, into every home, into every mind that can receive it. Is not that the most promising thing for civilization that was ever projected? It is something tidal, something seismic, and who can say what its effects may be?

Civilization Just Starting its Stride

Of course we have to remember that the trend of our age is materialistic, and bright young minds turn naturally to science and mechanics where in other days and other lands they would turn to sculpture, painting, and poetry. Every garage mechanic is tinkering with some invention, Jim and Dick and Tim rig up a "laboratory" in the attic. The Wright brothers started with a bicycle repair shop. Today's genius must work in today's mediums.

In literature, the trend is to fiction. When father was a boy he used to hide his murder story inside his geography and get a thrashing if the teacher caught him at it. Now daughter is in a story-writing class in college and mother is taking a course in the woman's club to learn to write stories with murders more mysterious and baffling than ever raised father's hair in days of yore.

Great minds may smile at these things as childish performances, but what we are witnessing is the spectacle of a whole people beginning *en masse* to take hold of science and literature. It may produce nothing of permanent value today, or tomorrow, or in ten, twenty, or fifty years, but we see the soil being prepared, and the seed planted, on a scale never before known. It would be a hardy skeptic indeed who could look at all this and say there would be no harvest. Civilization, for the many, not for the few, is just getting into its stride. Browning had it right when he wrote "Grow old along with me. The best is yet to be."

"How is your doctor son getting on in his practise?"
"Excellently—he is now occasionally able to tell a patient there is nothing wrong with him."
—Philadelphia Evening Bulletin

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

REVIEWED

The Postmortem Examination By Sidney Farber, M D Quarto of 201 pages, illustrated Springfield, Ill, Chas C Thomas, 1937 Cloth, \$3 50

I found this book to be an exceptionally clear, concise, and complete presentation of the procedures common to the autopsy room. While it definitely meets the need of a guide-book for a young pathologist it also presents the more modern autopsy technic in such a manner as to make it attractive and useful to anyone continuously engaging in necropsy work.

FLOYD S WINSLOW

Applied Physiology By Samson Wright, M D Sixth edition Octavo of 686 pages, illustrated New York, Oxford University Press, 1937 Cloth, \$6 00

The sixth edition of Wright's Applied Physiology is a considerable enlargement over the previous. This enlargement was not only desirable but necessary. The increase

of some hundred pages greatly enhances the value of the book since there is less tendency for it to be encyclopedic than heretofore. More space is given to a discussion of the various topics of current interest, so that those readers desiring a synoptic review of recent advances in physiology will find the information concise and clearly presented.

G B RAY

International Clinics A Quarterly of illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment Medicine, Surgery, Neurology, etc Edited by Louis Hamman, M D Volume 1, 47th Series Octavo of 310 pages, illustrated, Philadelphia, J B Lippincott Company, 1937 Cloth, \$3 00

This issue of the Clinics is predominantly pulmonary, cardiac and nephritic, and contains articles on these subjects which are most informative. Hyperthyroidism and hypothyroidism are discussed in three articles.

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W 42nd St N Y C) postage prepaid. Order must be accompanied by remittance covering published price.

BOOKS

This volume contains articles by our Brooklyn conferees which are of the same high standard of studies always presented by these authors. It will be found instructive if studied.

HENRY M. MOSES

A Brief Outline of Modern Treatment of Fractures By H. Waldo Spiers, M.D. Second edition. Octavo of 137 pages, illustrated. Baltimore, Wilham Wood & Company, 1937. Cloth, \$2.00.

This is a second edition of a small, compact and concise volume on the treatment of fractures. It shows improvement over the first edition in that a chapter on *Fractures of the Mandible and Maxillae* has been added, and the chapters on hip, ankle and foot fractures have been expanded to more completely cover the subjects. The new illustrations are more numerous, and have been well selected to clarify the text. The work is valuable for the general practitioner, and should be placed in the hands of every intern doing duty on the ambulance or in accident wards. It puts the essential principles of fracture work in a most easily accessible form for quick and ready reference.

H. W. BENOIT

The Cardiac Glycosides A series of three lectures delivered in the College of the Pharmaceutical Society of Great Britain under the auspices of the University of London. By Professor Arthur Stoll, M.D. Quarto of 80 pages, illustrated. New York, Sandoz Chemical Works, Inc., 1937. Cloth.

This book consists of three lectures delivered by the author in the College of the Pharmaceutical Society of Great Britain under the auspices of the University of London. It is a scholarly survey of the subject, and includes previous investigations of the cardiac glycosides (better known in the U.S. as glucosides) as well as studies made by the author himself. The work deals chiefly with chemical and pharmaceutical research, especially of the newer glycosides with no reference, however, to their clinical application.

CHARLES SOLOMON

Woman's Prime of Life Making the Most of Maturity. By Isabel E. Hutton, M.D. Duodecimo of 150 pages. New York, Emerson Books, Inc., 1937. Cloth, \$2.00.

This little book has been written primarily for the lay public, and women generally will gain much useful information by a perusal of its chapters. Many of their fears will be allayed by the clear and useful knowledge set before them, and they will approach and live through a dreaded period of life with much more equanimity due to the teachings of this little volume.

The chapter on *Advice to Husbands* is especially valuable and it should serve to ease the tension which clouds many marriages at this period.

The medical profession, too, will learn much of interest and value from a study of these chapters, and will find it an excellent book to recommend to patients. The advice given is sound, it is based on well-founded opinion, and covers the subject thoroughly. Dr. Hutton is an author with considerable experience in psychology, which gives added value to a volume on this subject.

WILLIAM S. SMITH

Clinical Allergy Due to Foods, Inhalants, Contactants, Fungi, Bacteria and Other Causes Manifestations, Diagnosis and Treatment. By Albert H. Rowe, M.D. Octavo of 812 pages. Philadelphia, Lea & Febiger, 1937. Cloth, \$8.50.

This pretentious volume embraces the entire field of clinical allergy. All of the material contained in the author's former monograph on food allergy is included, but is now distributed throughout the work. Incorporated in the book are many chapters on recent phases of allergy, such as, allergic conjunctivitis, gastro-intestinal diseases, migraine, allergic dermatoses, facial and dental deformities, etc. The bibliography is complete and up to date. One gathers the impression, however, that the material has been assembled in great haste and without careful critical analysis. The author seems willing to accept almost any theory as to the allergic nature of various illnesses. The author's valuable contributions on food allergy, so well co-ordinated in his previous book, are lost in this attempt to cover the entire field.

MATTHEW WALZER

The Ocular Fundus in Diagnosis and Treatment. By Donald T. Atkinson, M.D. Quarto of 142 pages, illustrated. Philadelphia, Lea & Febiger, 1937. Cloth, \$10.00.

This is a companion to Dr. Atkinson's book on external diseases of the eye which appeared not long ago. A brief history of the ophthalmoscope is given and the different methods of using it explained. The various normal fundi are described with their details. Anatomy of the retina with its vessels, the optic nerve and the choroid are briefly given and the various departures from normal described as they appear to the ophthalmoscopist. At the end of the volume are fifty-eight colored plates. These plates vary in value to the clinician, as some are much truer to life than others.

RALPH I. LLOYD

Elements of Orthopaedic Surgery By N. Ross Smith, F.R.C.S. Duodecimo of 246 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$4.00.

This small handbook presents the elements of orthopedic surgery in a straightforward and concise manner. Just the main essentials of each subject are given. Nothing is discussed in too much detail. There are enough illustrations to clarify the reading matter.

The book is especially valuable for nurses and masseuses who assist the orthopedist. Medical students, as well as general practitioners will find this little volume helpful.

CARMELO C. VITALE

A Text-Book of Mental Deficiency (Amentia) By A. F. Tredgold, M.D. Sixth edition. Octavo of 556 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$7.50.

Mental deficiency has not been given the attention it deserved. We have not taken it seriously from the medical point of view. The afflicted have been allowed to shift about for themselves with what help they could get occasionally from kindly disposed relatives. With increased public interest, and the organization of school clinics, better facilities for the care and study of such cases have been developing. In many schools special classes are provided, and for the more backward, special schools have been established at public expense. In this medium sized book, the author covers the various phases of the subject in an instructive way beginning with our concept of the condition, incidences and etiology, and following through with classification, psychology, pathology and a descriptive study of the different types with method of examination, diagnosis, prognosis, and treatment. There is a discussion of the clinical variations of primary and secondary amentia and so-called idiots savants. Moral deficiency is discussed in its relation to crime. It is a good book to add to the library of any person interested in child guidance and crime.

ARTHUR E. SOPER

Urological Roentgenology A Manual for Students and Practitioners. By Miley B. Wesson, M.D. & Howard E. Ruggles, M.D. Octavo of 269 pages, illustrated. Philadelphia, Lea & Febiger, 1936. Cloth, \$5.00.

This book is intended mainly, as the authors state, to be a primer for the amateur in roentgen urology. It is a brief but fairly inclusive study of the subject. In spite of its size there is sufficient mention of clinical findings and of urinary pathology to enhance its value particularly to the

general practitioner as well as a roentgenologist. The X-ray illustrations are numerous, films are markedly reduced in size. The reproductions are for the most part satisfactory. The illustrations are well annotated and worth careful study, particularly those dealing with traumatism of the urinary tract.

To all interested in urological roentgenology this volume will be worth careful perusal.

E. MENDELSON

Fundamentals of Human Physiology By the late J. J. R. Macleod, M.B. and R. J. Seymour, M.D. Fourth edition. Octavo of 424 pages, illustrated. St. Louis, The C. V. Mosby Company, 1936. Cloth, \$2.50.

This is a textbook of Physiology primarily for college students. It is clearly and simply written and brought up to date in this latest revision.

GEORGE B. RAY

The Intellectual Functions of the Frontal Lobes A Study Based upon Observation of a Man After Partial Bilateral Frontal Lobectomy. By Richard M. Brickner, M.D. Octavo of 354 pages, illustrated. New York, The Macmillan Company, 1936. Cloth, \$3.50.

This book reports detailed observations of a middle aged male patient from whom 116 grams of frontal lobe tissue were excised incidental to the removal of a large meningioma. The observations include the usual objective psychological examinations and reports of an informal character gained through day by day contacts. One is impressed on the whole with the relatively high degree of intellectual and personality preservation. Dr. Brickner has emphasized the quantitative rather than the qualitative nature of the aberrancies observed. He expresses the belief that all aberrancies of the patient are based upon a primary defect in executing complex syntheses of mental units. The relevant literature is capably woven into the presentation, which represents to date the most detailed and precise report available of the behavior of a human deprived of a considerable portion of both prefrontal lobes.

RUSSELL MEYERS

A Text-Book of Physiology By H. E. Roaf, M.D. Second edition. Octavo of 679 pages, illustrated. Baltimore, William Wood & Company, 1936. Cloth, \$6.75.

This text of Physiology is obviously written for the English student. There is distinctly less detail than in the usual text in physiology used by American students. Few references are given.

GEORGE B. RAY

BOOKS

November 1 1937]

The Diagnosis and Treatment of Arthritis
By Russell L Cecil, M D (Reprinted from
Oxford Monographs on Diagnosis and
Treatment) Octavo of 263 pages, illus-
trated New York, Oxford University
Press, 1936 Cloth, \$4.75

This book, a reprint from *Oxford Mono-
graphs on Diagnosis and Treatment*, is a
passionate, much-to-the-point considera-
tion of the diagnosis and treatment of
arthritis. Arthritis is first classified in a
practical workable manner. Various forms
of the disease are treated succinctly and in
turn. Theoretical considerations are merely
touched on rather than elaborated, the brief
but intelligible references to pertinent
theories are, however, supplemented by
rather complete bibliography. The book is
readable, it should be helpful to the every-
day practitioner of medicine who must read
as he runs. Years of practical experience
of a veteran student of the disease are
made readily available by this small vol-
ume. It is apparently written for the prac-
ticing doctor.

GEORGE E ANDERSON

Synopsis of Pediatrics By John Zahor-
ky, M D Second edition Duodecimo of
167 pages, illustrated St. Louis, The C V
Mosby Company, 1937 Cloth, \$4.00

This second edition has many changes,
and reference can be made only to a few
of them. The sections on Diagnosis and
Therapeutics have been brought up to date.
Some of the new sections are: Mental De-
velopment, Skin Diseases in the Newborn,
Nutritional Edema, Erythema Infectiosum,
Undulant Fever, Glandular Fever, The
Reticulo-endothelioses, Cysts of the Lung,
Subacute Bacterial Endocarditis, Amaurotic
Family Idiocy, etc. There is a new chap-
ter on Diseases of the Eyes and Ears.
Several color plates have been added, which
increase the value of the text.

In the chapter on tuberculosis the authors
have adopted one of the modern methods
of classification: 1 Infantile type 2 Juven-
ile type 3 Adult type 4 Extrapulmon-
ary tuberculosis. The main facts are re-
corded, and much controversial matter is
omitted, which is a relief after the stren-
uous debates that have been going on. We
could wish that surgical treatment had re-
ceived more attention.

Acute respiratory infection has a good
grouping under the main title, and special
infections are dealt with later. Mental de-
ficiency is approached from the general
standpoint, and the outline given is helpful
from that angle. We are unable to find
some of the things that are almost routine
in treatment, such as mandelic acid or
ketogenic diet in pyelitis, and sulfonamide
in hemolytic streptococcal infections.

It should be considered as its name im-
plies, a *Synopsis of Pediatrics*, and it is
remarkable how much material is con-
densed in its 357 pages. It well fulfills its
mission as a practical guide.

ARCHIBALD D SMITH

**Historical Notes on Psychiatry (Early
Times—End of 16th Century)** By J R.
Whitewell, M B Octavo of 252 pages Phila-
delphia, P Blakiston's Son & Co, 1937
Cloth, \$4.25

This is an interesting treatise describing
with some detail the evolution of psychiatry
through the ages. It includes a survey of
the literature in which the writings from
many languages are discussed and analyzed,
and an attempt made to compare ancient
description, nomenclature and diagnosis
with our present day knowledge.

A M RABINER

The Larynx and Its Diseases By Cheva-
lier Jackson, M D and Chevalier L Jackson,
M D Octavo of 555 pages, illustrated
Philadelphia, W B Saunders Company,
1937 Cloth, \$8.00

The publication of this book marks an
advent in the progress of laryngology.
There has been no work on the larynx re-
cently published that covers the subject for
the laryngologist in the manner that this
book does. It presents the entire subject,
as its name implies, beginning with anat-
omy and taking in every possible abnor-
mality, injury and disease. The *Notes on
Vursing Tracheotomized Patients* are es-
pecially valuable. This is indeed a most
complete volume, well arranged, replete with
sketches, drawings photomicrographs, illus-
trations, and a great number of colored
plates, which vividly reproduce the patho-
logical conditions as visualized by the
authors. One could go on indefinitely ex-
tolling the authors and their work. The
practitioner and laryngologist alike will find
the book a most useful addition to his
library.

SAMUEL ZWERLING

The Basis of Clinical Neurology The
Anatomy and Physiology of the Nervous
System in Their Application to Clinical
Neurology By Samuel Brock, M D Octavo
of 360 pages, illustrated Baltimore, Wil-
liam Wood & Company, 1937 Cloth, \$4.75

Dr Brock's work is an excellent com-
pendium of most recent literature dealing
with neuroanatomy and neurophysiology,
and reveals a broad insight into this im-
portant subject which lies at the base of
clinical neurology and is so important for
its proper understanding. It would appear
better adapted for the use of the neuro-
psychiatrist than for the medical student,
as the treatment of the subject is detailed,

and at the same time, the knowledge of the reader is assumed as to much that is elementary. The book is profusely illustrated by diagrams, and contains an excellent bibliography and a good index.

FREDERIC C EASTMAN

A Laboratory Manual of Physiological Chemistry By D Wright Wilson, Third edition. Octavo of 288 pages. Baltimore, The Williams & Wilkins Company, 1937. Cloth, \$2 50.

The manual is divided into two parts. The first deals with various tests for the detection of inorganic constituents such as phosphorus, calcium, magnesium, sulphur, chloride, and nitrogen. There are also chapters on preparation of standard solutions, hydrogen ion concentration, colloidal solutions, and tests for various carbohydrates, proteins, and fats. The second part of the manual deals with the chemistry of body tissues and fluids. This includes chemical tests of the saliva, gastric and pancreatic juices, milk, blood, bile, bone, muscle, and urine. The tests are concise, and without any burdensome details.

EDWARD H NIDISH

The Patient and the Weather By William F Petersen, M.D. Volume I, Part 2—Autonomic Integration, \$9 00 and Volume IV Part 1—Organic Disease Cardio-Vascular-Renal Disease Including a Chapter on Experimental Endocarditis by Alexander J Nedzel, M.D., \$10 00. Quarto, illustrated. Ann Arbor, Edwards Brothers, Inc., 1937. Cloth.

Both of these volumes are part of a series of monographs by the author. In them, as well as in the other volumes, he has advanced the assumption that meteorological alterations are of primary importance in the reduction of disease processes. This thesis has been expanded in the other books of the series.

In Part II of Volume I, the author discusses constitution, the limits of biological reaction as regulated by the autonomic apparatus, the meteorological environment and finally, studies of this integration as made evident in the observation of normal individuals living in the midst of storm tracks. It deals primarily with normal autonomic integration. In later volumes the author presents the clinical evidence for dysintegration (disease). For him there exists two main types of individuals—psychic and leptosomic—that react differently to meteorological alterations.

In Part I, Volume IV, the author is primarily interested in the demonstration that organic disease may take its origin from environmental stimuli. Even though Petersen is a pathologist he evidences his interest in the beginning of the disease of

major organs rather than in the final picture as determined at autopsy. To prove his point he has selected a series of commoner diseases and by means of charts, case histories, etc., he demonstrates the effect of the weather on the production of cardio-vascular-renal diseases. There is also appended a chapter by Dr A J Nedzel, Associate Professor in the Department of Pathology, College of Medicine, University of Illinois, on experimental bacterial endocarditis in dogs, emphasizing the importance of meteorological alterations in the production of an increased permeability of the valvular endothelium.

These volumes, as well as the others of this comprehensive and scholarly monograph, are printed in a new format which permits them to be sold at lower cost.

JOSEPH L ABRAMSON

Out of the Test Tube By Harry N Holmes, Ph.D. New edition revised and expanded. Octavo of 301 pages, illustrated. New York, Emerson Books, Inc., 1937. Cloth, \$3 00.

The revised edition of this work, prepared for popular and nontechnical consumption, tells the story of chemistry through historical development to its modern importance in various fields of industry. Despite its scope, considerable material is directly applicable to the field of medicine, much of such information being unusual and sometimes surprising because of novel treatment. Definitely not the usual type of book reviewed in these columns, the casual medical reader will find it holding his interest and frequently providing a new viewpoint for much of his medical thought.

IRVING M DERBY

Short Wave Diathermy By Tibor de Chohnoky. Octavo of 310 pages, illustrated. New York, Columbia University Press, 1937. Cloth, \$4 00.

Although the introduction of short wave therapy is comparatively recent, an extensive literature has already been contributed on the subject. Much of this and the claims made for the treatment border on the fantastic, so that a text of the kind here offered fills a definite want. This book is based on actual clinical experience, with the necessary considerations of physics uncolored and undistorted to fit any set theories. Opinions of various workers in the field of short wave therapy are quoted extensively. Conditions amenable to treatment are carefully considered, and application of the therapy clearly described in many instances. The book is well written, clearly printed and illustrated, and can be recommended to students and practitioners of physical therapy.

SPINAL ANESTHESIA

Its Use and Limitations

ORVILLE C KING, M D, *Philadelphia, Penn*

Spinal anesthesia (subarachnoid analgesia) we believe has a definite place among anesthetic methods. The basis for this statement is our personal experience with this method in 10,000 cases over a period of ten years. Following Pitkan's contribution in 1926, surgeons throughout the country accepted the spinal method enthusiastically, but after a few years many of the same group became adverse to its use. If one analyzes the literature on spinal anesthesia during that time, one can appreciate that such a reaction was to be expected, because cases were improperly selected for this anesthetic. We were led to believe, or, at least thought, that the spinal method should be allotted to the debilitated, emaciated, and shocked. These patients did not withstand this anesthesia, and many deaths followed, the casualties which resulted being most often the fault of the surgeon or the anesthetist, who selected such a method. In other words, we were unfamiliar with the actions of an anesthetic agent introduced into the subarachnoid space. Later, with the researches of such workers as Ferguson and North, Bower, Cotui, Fagan and Wrightman, Seevers and Waters, and many others—together with their clinical experience—the knowledge and the use of this method were increased and changes in technic were introduced.

Formerly, many writers reported complete failures as well as neurogenic complications, and the writer himself, in 1933,

reported 13 per cent of failures in 1500 cases.¹ In the last 7500 cases, there has not been one complete failure. Neurologic complications, which appear to be the result of faulty technic, are less frequent. Shamberg, reporting 14073 cases in 1935 where spinal had been used, had only three cases of transient peripheral neuritis.² Consequently, during the past five years, this anesthetic method has been given on a more scientific background with better results.

We view the use of spinal anesthesia in a conservative manner, and believe the area to be operated upon under spinal block should never be above the diaphragm, as it has been shown that shock increases with the height of the anesthetic agent.³ As the anesthetic tends to rise, the accessory muscles of respiration, being rendered useless, the danger is increased. If such height is reached to include the vital centers, especially the respiratory and cardiac ones, paralysis of their activity will follow.⁵ We do not agree with Koster and others who advocate spinal anesthesia for a higher field.

With only the area below the diaphragm to be utilized, the use of spinal is limited, and it possesses special advantages in surgery upon the gastrointestinal tract, gall-bladder, and spleen. Due to the extensive relaxation, tension upon the viscera is minimal and visualization is increased. Marked retraction of the

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 25, 1937*

abdominal walls and large packs are unnecessary, the collapsed intestines acting as accessories to this. In addition, the closure of the abdomen is rendered less difficult, a factor in the prevention of postoperative evisceration and herniation.

Urological surgery, for the most part, is performed upon individuals the majority of whom are beyond fifty years of age, and who have an impairment of kidney function. This fact was apparent in the analysis of a group of 1534 cases, for 62.4 per cent were between the ages of fifty and eighty-eight. Bearing such facts in mind, the anesthetic agent should be one which will neither increase metabolism nor further kidney damage, and preferably one which does not induce the loss of consciousness, which is so frequently a cause of apprehension in those of advancing years.

With the exception of kidney surgery, the operative area in urological patients is confined to the bladder and prostatic bed, this being true in 63.1 per cent of the 1534 cases reviewed.

Consequently, the anesthetized field is low, the amount of the agent used is small—averaging seventy-five mg.—and there is practically no shock. For this reason transurethral surgery offers an ideal field for spinal anesthesia.

Operation upon the kidney is usually undertaken in younger individuals—between thirty and forty years of age—and a larger field block can be included without undue risk. Such patients under spinal anesthesia present to the surgeon a complete relaxation which enhances kidney exposure and allows for an easier delivery of this organ. There is greater access to the pedicle, consequently a better opportunity for secure ligation of its vessels. In Dr. Leon Herman's clinic spinal anesthesia has practically displaced all other forms. During the past year, eighty-five per cent of urological operations have been performed on patients so anesthetized.

Children's surgery offers another field for spinal anesthesia, and while we have not used it extensively, yet in those cases in which it has been tried, the results have been most satisfactory. Physiologically, children are ideal for this method.⁶ They are not apprehensive and are for the most part cooperative, and tolerate fairly large

amounts of the anesthetic agent. We have used the spinal method in very young babies when operating for the relief of pyloric stenosis, with fewer complications than with either local infiltration or ether. In children with generalized peritonitis, the relaxation which is given by the use of spinal block allows for a rapid exploration with minimum loss of tissue fluids. Nausea and vomiting rarely follow, thus promoting a smoother convalescence. For a thorough evacuation of the colon in cases of Hirschsprung's disease, the introduction of a small amount of procaine into the subdural space has no equal, and it can be used as a diagnostic aid in this condition.

For surgery upon the lower extremities, the spinal method has proven valuable for here, as in surgery upon the prostatic bed, the area to be anesthetized is low and only small amounts are necessary. In fractures, the relaxation permitted allows for complete reduction with the least trauma.

Dislocations, likewise, are readily reduced. Amputation, when diabetes complicates, is an indication for spinal anesthesia. It is also safer than local infiltration, as often there is present an inflammatory reaction with a resulting slough and ulceration.

Spinal anesthesia should never be used routinely, as this destroys individualization, the condition and needs of the patient are neglected, and carelessness soon supervenes both on the part of the anesthetist and the surgeon. Routine also tends to a disregard of the dangers of the method, and sooner or later an accident will occur, the blame being improperly placed on the method rather than on the anesthetist himself where it properly belongs. The novice should not be given the responsibility of administering this anesthesia, and yet only too frequently a Junior Intern is entrusted with the procedure. It follows that the success of spinal anesthesia increases with the anesthetist's training. The ease with which many spinals can be given soon gives the untrained a false sense of security and it must be remembered that once the agent is introduced, it cannot be removed, nor its action stopped. The anesthetist must be familiar with the reactions that may present themselves, consequently he must continually and intelligently interpret the

SPINAL ANESTHESIA

November 15, 1937]

clinical signs and symptoms as they occur and know how to recognize and properly treat the untoward ones.

We advocate training of these individuals who are to be responsible for patients anesthetized in this manner. This training should include the opportunity of inducing the anesthesia under guidance of the anesthetist shows himself capable of caring for patients so anesthetized. We all recognize that the mortality of spinal anesthesia decreases with the individual's increased experience, so poignantly shown by North.⁷

As our experience with spinal anesthesia has increased, we have learned that the contraindications to its use have become less in number. Since the shock factor depends primarily upon the number of white rami involved, the anesthetization of the upper abdomen has the greatest number of contraindications. Our guide for the selection of patients is the elasticity of the cardiovascular system, this being adjudged by a careful history and physical examination with special reference to this system, electrocardiographic and other special studies being made when indicated. Spinal anesthesia, just as any other anesthetic, is best employed in young, robust individuals. In certain pre-operative complications, however, making a choice of anesthetic agents necessary, we employ the anesthetic which will be the least harmful, the selection thereby becoming an individual problem, and not based on hard and fast rules.

Such complications as exist when there is pathology of the central nervous system or its environs must rule out subdural analgesia, infection at the site of puncture also contraindicates its use. In patients with marked cardiovascular disease, the area to be anesthetized must be confined to the lower abdomen. Hypotension is a contraindication when not present in an otherwise normal individual and especially when the hypotension is due to surgical shock or hemorrhage. Too frequently, the anesthetist and surgeon do not appreciate that a lowered tension generally follows when spinal is employed in the upper abdomen. When the systolic blood pressure drops to eighty or seventy mm of mercury with a corresponding diastolic decrease, this is reported to the surgeon who usually immediately orders

a stimulant, thus inducing an unjustifiable temporary rise in blood pressure. Without such measures the blood pressure will remain at this lower level until the procaine loses its effect, provided no great loss of blood has been encountered.

A better guide to the condition of the patient, we feel, is the pulse pressure, the pulse rate and rhythm, the even but lowered respiratory rate, and the patient's general appearance. Stimulating drugs should *only* be used preanesthetically, and we give ephedrine twenty-five mg in practically all cases. During the last 7500 cases no other stimulant has been given after the initial injection and there have been no deaths. Tovell of the Mayo Clinic reported the use of benzedrine as an inhalant to combat the fall of blood pressure, and while the number of cases was small, he did show an increase in twenty-nine of the thirty-one instances in which it had been given.⁸ Further studies in this field are necessary. If shock becomes severe the intravenous instillation of blood, glucose or saline should be employed, this having been necessary only nine times in our experience, each time due to loss of large amounts of blood.

Due to the sudden change of intra-abdominal pressure, care must be taken in the employment of spinal anesthesia for the removal of large abdominal masses. North,⁷ Veal and Van Werden⁹ comment upon this, each mentioning several cases in their own experience resulting in a mortality.

I would like to offer several suggestions for the care of patients who are to receive spinal anesthesia.

- 1 Assure the patient that it will be a painless procedure and make it so.
- 2 Proper evaluation of the blood pressure, pulse, respiration, and general appearance of the patient during the anesthesia.
- 3 Sympathetic assurance to the patient at all times.
- 4 The addition of another anesthetic agent before the spinal loses its effect, if indicated.
- 5 The use of the Trendelenburg position only when the operation necessitates.
- 6 Careful transfer of the patient from operating room table to his bed.
- 7 Careful observation postoperatively by a nurse trained in the care of patients who have received "spinal" until the effects of the anesthetic have disappeared.
- 8 Comfort and assurance of the patient at all times cannot be overemphasized.

Summary

Inexperience and improper selection of patients were the most important reasons for the earlier accidents in spinal anesthesia. We advocate special training for anesthetists using this form of nerve block.

Subarachnoid anesthesia is limited, in our opinion, to operations upon the area below the diaphragm.

The value of spinal procedure has been mentioned and individual selection of patients and their treatment especially advocated.

The contraindications have been given in some detail and several suggestions for the care of patients who have received spinal anesthesia has been outlined.

HINTS ON RUNNING COUNTY SOCIETY PROGRAMS

Among the pet peeves of county medical society secretaries and chairmen of program committees are speakers who are too technical or who speak beyond the allotted time, and members who are always late for meetings, remarks *The Ohio State Journal*.

A determined effort at least to ameliorate these conditions is being made by the Program Committee of the Academy of Medicine of Cincinnati, which recently announced the following set of rules.

1 A maximum time limit of twenty minutes for all local speakers appearing on the Academy programs. Two discussants of each paper will be allotted a maximum of five minutes each.

2 The President of the Academy has been requested to enforce this time-limit rule by giving a two-minute warning signal and calling for conclusion of the paper or discussion when the allotted time is up.

3 All meetings will start promptly at 8 15 o'clock. The habit of starting late only encourages members to come late. If

it becomes known that meetings started promptly at 8 15 regardless of the size of the audience at that moment, members will be stimulated to get to the meetings on time.

4 Members of the Academy, who are invited to appear on the Academy programs, will please observe the general rule that papers should not be too technical. The purpose of the Program Committee is to build programs that will help the greatest number of members and be of special interest to the general practitioner.

The adoption of a similar set of rules by all county societies, properly observed by speakers and members, plus a courageous chairman, should provide the interesting, snappy programs which will insure a good attendance.

Incidentally, since the establishment of a Speakers Bureau by the Ohio State Association, there is no longer any reason for program committee chairmen to worry about where to get guest speakers occasionally for county society meetings.

WHY IT WAS

Two or three New York State physicians are qualified to fill the State Health Department post to which Dr Rosslyn Earp of Santa Fe, N M, has been appointed, but they were not attracted by the salary of \$4,500.

That is the reason given by Dr Edward S Godfrey Jr, state health commissioner, as reported in an Albany paper, for not appointing a New York man to the new job of medical editor in the division of health education.

In Dr Earp's acceptance of the appointment, Dr Godfrey said, the state should feel itself fortunate. The qualifications needed for the post, the commissioner pointed out, are a sound background in medicine and in public health, coupled with ability to write on both those subjects in a way that would attract lay readers.

All of these, Dr Godfrey said, are possessed by Dr Earp, whose training in medicine, health and literary work covers two continents.

THE ROLE OF ACUTE INFECTION IN HYPERTENSIVE CARDIAC FAILURE

JAMES R. LISA, M.D. and ALFRED RING, M.D., *New York City*
From the Pathological Laboratory, City Hospital, New York City Dept. Hospitals

It is common knowledge that only a certain percentage of hypertensive cases develop cardiac breaks. One naturally suspects therefore that an additional factor must be present in the cases comprising this group. This communication is the report of a study undertaken to determine the nature of the precipitating factor in the cardiac failure complicating some cases of hypertension.

Eighteen cases of decompensated hypertensive heart disease that came to autopsy at the New York City Hospital were made the basis of this study. Only those cases were accepted where the clinical features were predominantly cardiac in nature, where the systolic pressure was at least 150 mm Hg, and in which the histology of the kidneys revealed arteriolar sclerosis. There were eliminated from the series all cases with a recognized etiological factor of cardiac dysfunction, such as rheumatic fever and syphilis, cases of diffuse glomerulitis with hypertension, and cases of hypertension dying from uremia or cerebral hemorrhage. For control material several hundred hearts from autopsies performed between 1927-1934 were employed. They included cases of essential hypertension dying from uremia or cerebral hemorrhage, asymptomatic hypertension dying from unrelated conditions, diffuse glomerulitis cardiac cases of recognized etiology, and noncardiac cases, i.e., pneumonia, tuberculosis and malignancy.

In each of the cases the patient was under hospital supervision and therefore a satisfactory correlation between the clinical and pathological findings could be made. The evidence found and herein presented indicates infection to be the superimposed factor bringing about the cardiac breaks.

For the purpose of clarity and to indicate the character of the cases there is briefly summarized in Table I the sex, age, clinical type of case, course and manner of death.

Acute Lesions

The most frequent changes found in the hearts were the mottled gray-yellow and light brown color, the soft consistence, and the friability. Massive cardiac infarction was present in eight cases. It was usually limited to the left side of the heart, occasionally involving the right ventricle. Acute fibrinous pericarditis was present in five hearts. In four, it was diffuse, in half associated with an acute infarction. In one instance it was limited to the apex over an acute infarction. Acute coronary thrombosis was demonstrable only once. Spontaneous rupture of the aorta with hemopericardium was present in one case.

The histological examination revealed acute lesions to be much more frequent and more extensive than the naked eye appearance of the hearts would indicate. Miliary infarctions and necroses were present in ten hearts not affected by the gross infarction. Lesions of a similar character were found in the eight hearts with coarse infarction. In these hearts they were well beyond the acute lesion and frequently appeared to be in regions supplied, not by the artery feeding the site of acute infarction, but within the distribution of the opposite artery. An acute infectious myocarditis, either as a diffuse lesion or as miliary abscesses, was found in three cases. One of them was the case of aortic rupture. An acute fibrinous exudate limited to the apex of the pericardium at its reflexion over the roots of the large vessels was present in three cases, in one instance with myocardial abscesses. An acute medial necrosis involving the proximal portion of the right coronary artery was present in one case accompanied by miliary infarctions of both ventricles. An interesting feature of this heart was the distribution of the miliary infarctions. They were as extensive in the regions supplied by the left

Fig 1 Acute infectious myocarditis. This type of lesion was found in ventricles in the case of sudden death from aortic rupture and in two cases with infection.

Fig 2 Molecular degeneration of myocardial fibers. Microscopic lesion of myocardium found even in absence of massive cardiac infarction.

coronary and anterior descending arteries as they were in that of the right coronary artery. Young arteriolar thrombi were present in two instances, neither having a recent thrombosis of a main coronary artery.

Chronic Lesions

A diffuse thickening of the epicardium of the auricles and milk spots of the ventricles were almost universal findings.

TABLE I

No.	Sex	Age	Clinical Type	Course	Mode of Death
1	M	60	Congestive failure	Improving	Infection
2	M	32	Congestive failure	Slowly progressive	Infection
3	F	80	Congestive failure	Progressive	Infection
4	M	60	Congestive failure	Improving	Sudden
5	M	67	Congestive failure	Slowly progressive	Sudden
6	M	70	Combined	Progressive	Infection
7	F	38	Combined	Progressive	Pulmonary edema with death within twenty-four hours.
8	M	70	Combined	Quiescent for three months	Sudden

15	M	60	Anginal	Quiescent three weeks	Episode with death within twenty-four hours.
16	F	70	Anginal	Progressive	Episode with death within twenty-four hours.
17	F	68	Anginal	Progressive	Infection
18	F	55	Anginal	Progressive	Infection during episode

The ventricular milk spots were frequently much more prominent over the right side and especially over the right auricle. Healed infarction producing coarse myocardial scarring was present in twelve cases, in seven instances associated with an acute infarction. The condition of the superficial coronary arteries varied from normal or slightly atheromatous to intense sclerosis with canalized thrombosis. The anterior descending artery was particularly prone to display the more intense lesion.

The histological examination again presented evidence of more extensive lesions than were evident to gross inspection. Scarring of the myocardium—usually more marked on the left side—was fre-

quently present in the right ventricle, where it tended to be perivascular. Cellular reaction was frequent within and near the scars. It was predominantly lymphoid in character with a few plasma cells but all stages could be observed, from the acute polynuclear infiltration to the healed scar.

The intensity of the chronic cellular reaction beneath the epicardium proved to have one feature of particular interest. It was extremely dense at the apex of the pericardial sac in the region of the roots of the large vessels, the site of most marked involvement being over the vena cava. The location of this chronic lesion was similar to the acute focal lesion noted

Fig 3 Acute medial necrosis of proximal portion of right coronary artery, case of sudden death. Widespread myocardial lesion was similar to Fig 2

above as occurring in three cases. The adventitia of the coronary arteries frequently had an intense reaction, somewhat similar in character to that observed at the pericardial apex, usually with a greater admixture of polynuclear cells, monocytes and hemosiderin-bearing phagocytes. This reaction was associated with atherosclerosis of the artery but was much more intense than is usually seen in this condition. Certain differences (to be published in a later communication) exist between these changes and those occurring in the coronary arteries of cases of hypertension complicated by syphilis. Suffice it to

Fig 4 Marked perivascular scarring and dense chronic cellular reaction present in many cases

say at present, that they led to the conclusion that in the present series, the adventitial reaction was not syphilitic in nature.

To summarize, then, the following histological features suggest an infectious basis for the cardiac breaks:

- 1 Extensive acute myocardial degeneration associated with edema and acute cellular reaction
- 2 Chronic granulomatous lesion of the adventitia of the coronary arteries
- 3 Chronic granulomatous lesion of the

Fig 5 Chronic granulomatous lesion found at apex of pericardial sac, view taken from superior vena cava

epicardium, most intense toward the base of the heart

4 Acute diffuse pericarditis, in half the cases only attributable to an acute coarse infarction

5 Acute fibrinous lesion at the apex of the pericardial sac

Of value as an indication that the atherosclerosis of the coronary arteries *per se* was not the primal factor in the cardiac breaks was the great variability of the changes both in the larger arteries and the arterioles

There was further clinical and pathological evidence to support the hypothesis of an infectious basis for the cardiac breaks. The cases of sudden or rapid death were found the most instructive because the least complicated. Three patients with complete quiescence of cardiac symptoms for three months or longer died suddenly. Two had massive acute infarctions, one presenting an acute fibrinous lesion at the apex of the pericardial sac. One died of a ruptured aorta and had an acute infectious myocarditis. Sudden death occurred in three patients not completely compensated. Two had massive acute infarction, one with an acute thrombosis of the right coronary artery and acute focal glomerulitis. In the third patient, acute medial necrosis of the proximal portion of the right coronary artery was present, an acute diffuse fibrinous pericarditis, acute fibrinous pleurisy, and acute pyelitis (Tables II-III)

Five patients died within twenty-four hours of the onset of an acute break presenting the features of sudden left ventricular failure seen so frequently in coronary sclerosis. One patient had been completely free of cardiac symptoms for three weeks, mild coronary attacks had occurred in the others, although they were semiambulatory. Four had massive cardiac infarction. One of them, clinically quiescent for three weeks, had multiple acute arteriolar thrombi in the left ventricle and interventricular wall, the region involved by the acute infarction. In the fifth heart were widely distributed miliary lesions. Three of the five cases had acute lobar or confluent bronchopneumonia.

Of the eleven patients, therefore, dying suddenly or rapidly, there were in four of them acute pulmonary infections and in one an acute infectious myocarditis

TABLE II—SUDDEN DEATHS

No	Acute cardiac pathology	Associated pathological changes

6	Microscopic lesions of ventricles	Strept. hemo. septicaemia
9	Miliary abscesses LV IVW	Strept. hemo. septicaemia
		Sacral and iliac bed sores
		Acute pyelonephritis
		Acute pulmonary infarctions
17	Microscopic lesions of both ventricles	Impacted stone in ampulla of Vater
	Early arteriolar thrombi LV IVW	Acute suppurative hepatitis
	Fibrinous pericarditis SA region	Acute bronchopneumonia
		Acute suppurative nephritis
18	Microscopic lesions of ventricles and auricles	Strept. hemo. septicaemia
		Acute saddle thrombus of pulmonary arteries

It is of interest to note in the last case, that there had occurred a few days previously a mild pharyngitis. One other case of this group had evidence of infection in other organs, a focal glomerulitis. Six of the cases therefore had evidence of acute infection, most frequently intrathoracic. That the damage should be limited occasionally to the heart alone is not incompatible with the conception of infection. The tendency of superadded infection in the rheumatic heart to concentrate in previously damaged regions is conceded a normal course of events. The damage in the hypertensive heart is merely different in location, myocardial rather than valvular.

In the last group of seven cases, the gross pathological evidence was primarily that of infection. The clinical features in all of the patients were cardiac in nature, not those of infection as it ordinarily manifests itself. One case had an acute infectious valvular and mural endocarditis and diffuse infectious myocarditis. It was of interest to find in this case acute mural thrombi of the main pulmonary arteries. In a second case, miliary abscesses of the myocardium were found, the focus probably from decubital ulcers. The origin of the infection was demonstrable in three other cases—septic sore throat, suppurative pyelonephritis, and impacted gall-stone. A feature common to all the cases was acute broncho- or lobular pneumonia. The case of septic sore throat had in addition fibrinous pericarditis and acute infarctions of spleen and kidneys. In the case of impacted stone, the acute suppurative hepatitis was associated with young arteriolar thrombi of the myocardium, an acute fibrinous lesion at the apex of the pericardial sac, and embolic suppurative nephritis. A source of infection was not demonstrable in two cases. The pathological changes were those frequently seen however in streptococcal septicemia, petechial hemorrhages in the skin and serosal surfaces. It was of interest to find in one of them, acute mural thrombi of the pulmonary arteries similar to those present in the case of endocarditis.

The question which naturally arises in this last group is whether or not these infections are merely incidental terminal events bearing no relationship to the car-

diac breaks. Certain observations led us to conclude that there was a direct relationship. The clinical features were cardiac in nature, signs of infection were usually absent. Even when there was clinical evidence of infection the cardiac symptoms became greatly exaggerated and dominated the clinical features. The acute pathological changes in the hearts were more extensive than in cases of similar infections occurring in the noncardiac patient and were similar to those found in the cases of sudden or rapid death in the present series.

The last observation of interest was the chronic tubular bronchiectasis found in all cases. This site could well be the focus of infection affecting the heart. Some of the control material offered evidence to support this interpretation. Many of the hypertensive cases dying from a first cerebral hemorrhage, in whom the history of preceding cardiac dysfunction was entirely negative, had normal lungs except for acute terminal bronchopneumonia, unscarred myocardium, epicardium free of milk spots and the pericardial apex free of chronic granulomatous lesions.

From the pathological and clinical findings of these eighteen cases, a definite conception of the course of events leading to cardiac breaks in the hypertensive patient can be formulated. The focus of infection is usually the respiratory tract, either as a primary or metastatic process. The infection gains entrance to the heart through the apex of the pericardial sac, a region of rich anastomosis between the heart and lungs. The lymphatic channels seem the more important or at least the more constantly affected, resulting in the chronic granulomatous lesion of the pericardial apex and the acute fibrinous lesion occasionally found. A similar acute lesion is found not infrequently in the acute pneumonias terminating with cardiac failure. That the arterial system also appears to be the channel of involvement in some cases or at different times seems likely, judging from the distribution of the myocardial lesions in regions supplied by both arteries.

The study of the hearts discloses a definite series of events in the lesions of myocardial degeneration. The earliest change is a disturbance of the finer archi-

tectural pattern of the fiber. The cross striation undergoes a granular degeneration and swelling and changes from a delicate line to a series of coarse masses. The next stage is a disturbance of the relationship of the constituents of the fiber and replacement by a granular mass. The nucleus at this stage appears large and swollen. Then there occurs invasion by polynuclear cells, beginning disintegration of the muscle nucleus, disappearance of the granules, and a suggestion of local edema. Monocytes make their appearance, the polynuclear cells begin to disappear, and early peripheral connective tissue reaction sets in. Lymphoid cells appear and the monocytes disappear. With progressive fibrosis, the lymphoid cells become more and more scanty and finally only the scar remains.

The degree and extent of distribution of the acute parenchymal myocardial degeneration offered the most reliable

histological criteria of the clinical symptomatology. It seems more closely parallel to the clinical features than any other histological change. Neither the condition of the coronary arteries, the degree of hypertrophy, the extent of scarring nor the chronic cellular reaction appeared to offer so close a relationship.

Summary and Conclusions

Eighteen cases of decompensated hypertensive heart disease are reviewed. Histological evidence is presented that infection is the factor precipitating the cardiac breaks. The focus of infection is usually the lungs. The channels through which the heart is affected lie at the reflexion of the pericardial sac over the roots of the large vessels. The acute parenchymal myocardial damage offers the best histological criterion to the clinical cardiac features.

CITY HOSPITAL

A CHEMICAL BREATH-SMELLER

"A mechanical nose took three sniffs today and pronounced one man sober, another intoxicated," says a press dispatch from Baltimore.

Two sniffs were for a youth who gulped two ounces of liquor at a demonstration of the sobriety testing service.

The other was for a fellow subject who downed four ounces of whisky in a room with envious policemen gathered on all sides.

A bit of pink liquid in a tube gave the answers. It grew a shade or so lighter for mild intoxication, colorless for a "real drunk."

Dr R. N. Harger of Indiana University devised the "chemical smeller" and demon-

strated it before the convention of the International Association of Chiefs of Police.

The whole unit is built around reaction to alcohol of permanganate and sulphuric acids and water and a supply of toy balloons. The chemicals form the chameleon-like liquid and the balloons the "sniffers." Subjects breathe into the balloons. Then the balloons are placed on a tube. The air bubbles merrily into the liquid.

"When the quantity of breath required (to change color) is less than one pint, the subject is usually intoxicated," Dr Harger said. "With deeply intoxicated subjects, the color of the fluid is removed by only a few ounces of breath."

The New York Academy of Medicine is giving its third series of Lectures to the Larty from October 28 to May 26 on "The Art and Romance of Medicine." All meetings begin promptly at 8 15 p. m. The program is as follows:

October 28—"From Barber-Surgeons to Surgeons, The Evolution of Surgery as a Profession" Francis R. Packard, M.D., Editor of *Annals of Medical History*.

November 24—"The Meaning of Medical Research" Alfred E. Cohn, M.D., Member of the Rockefeller Institute for Medical Research.

December 23—"Dr. Watson and Mr. Sherlock Holmes" Harrison Stanford Martland, M.D.,

Professor of Forensic Medicine, New York University College of Medicine.

January 27—"Medicine in the Middle Ages" James J. Walsh, M.D., Extension Professor, Fordham University.

February 24—"The Search for Longevity" Raymond Pearl, Ph.D., Professor of Biology, Johns Hopkins University.

March 24—"The Physician's Contribution to Medicine." Edward Elway Free, Ph.D., Consulting Physician.

April 28—"Medicine and the Progress of Civilization" Nicholas Murray Butler, President, Columbia University.

May 26—"X-ray Within the Memory of Man" Lewis Gregory Cole, M.D., Consulting Roentgenologist, Fifth Avenue Hospital.

MANTOUX TEST IN PEDIATRICS

Increased Significance and Importance to the General Practitioner—Report of 1000 Cases

JOSEPH BATTAGLIA, M D and FRANK L. ROSEN, M D, *Brooklyn*
From the Pediatric Service of Kings County Hospital, Long Island College of Medicine Division

When there is so much of medicine that we do not understand it is a pity that we do not utilize the knowledge we already possess. Such is the case with the Mantoux test for the diagnosis of tuberculosis so widely used by the pediatrician, yet so rarely performed by the general practitioner.

For many years, in many communities, physicians have noted a marked decrease in the incidence of positive Mantoux reactions in children (adults also). As routine tests begin to show less "positives" so does the value of the test become enhanced for the diagnosis of tuberculosis. Since so few positive skin tests occur in infants and children, the value of this simple test is now so great, that the Metropolitan Life Insurance Company has undertaken a nationwide advertising campaign to inform the public about the tuberculin test. No large series report, based on the incidence of positive tuberculin tests, has as yet been published from Brooklyn, a community of 2,700,000.

This article is based on a clinical study of 1000 cases from the inpatient children's medical service of King's County which is Brooklyn's largest municipal general hospital and draws its patients from the lowest economic strata. It is well-known that these patients present the highest incidence of tuberculosis and any evaluator of statistics must bear this in mind, for as we go higher and higher in the socioeconomic scale, the incidence of tuberculosis and its parallel, the incidence of positive Mantoux reactions decline thus rendering the tuberculin test indispensable.

The testing material used was supplied by the Health Department of New York City for all city hospitals. It consists of a ten c.c. vial of salt solution and a capillary tube containing 0.1 c.c. of old tuberculin. When the two are mixed the resulting solution is a 1:1000 dilution of old

A tuberculin syringe is then used to inject 0.1 c.c. of this solution intracutaneously into the volar surface of the forearm, thus the amount of old tuberculin injected is 0.1 mg. In suspected cases of tuberculosis, if the reaction is negative to 0.1 mg., lower dilutions are used and we inject one mg. and if that is negative ten mg. of old tuberculin.* Whatever testing material remains in the vial after forty-eight hours is discarded and care is taken not to allow alcohol to remain in the tuberculin syringe. The test is read forty-eight hours after the injection and recorded as 1+, 2+, 3+, or 4+. The presence of an edematous area of at least five mm. in diameter is required for a positive reading.

In our series only two severe reactions were observed as a result of our thousand injections. Both of these occurred in children over six and the symptoms consisted of swelling of the entire arm with a temperature reaction of 102° F. The swelling and temperature subsided with no complications in one week's time. Strangely enough neither of these two cases was a proven clinical case of tuberculosis. The results of our investigation are shown in Table I.

Of the thousand cases, 67 per cent had positive Mantoux tests, 35 per cent had skin reaction without clinical evidence of tuberculosis, and 32 per cent had positive clinical evidence of tuberculosis. Of the positive Mantoux reactors, 47.7 per cent clinically or radiologically manifested tuberculosis. This finding gives the tuberculin test great significance. In discussing the importance of this test, Webb² states "The skin reaction constitutes at present the most important single diagnostic method in childhood tuberculosis." Thus certainly if only for economic reasons a tuberculin test should be per-

* It is a rare occurrence to obtain a positive reaction at a second or later test when the first is negative.¹

TABLE I

Age	No. of cases	Total positive Mantoux	No. of tuber proven	Total incidence positive Mantoux inc. tuber cases	Incidence positive Mantoux exc. proven tuber cases	Incidence of proven tuber in series by age
To 1 year	252	1	0	0	0	0%
1 to 3	230	14	0	0	0	0%
3 to 5	144	10	5	4%	4%	0%

TABLE II—SEX INCIDENCE OF POSITIVE SKIN REACTION

Sex	No. of cases	Total positive Mantoux	No. of tuber proven	Total incidence positive Mantoux inc. tuber	Incidence positive Mantoux exc. tuber	Incidence of tuber
Male	587	42	21	7%	3%	3%
Female	413	25	11	6%	3%	2%
Total	1000	67	32	67%	35%	32%

TABLE III—RACE INCIDENCE

Race	No. of cases	Total positive Mantoux	No. of tuber proven	Total incidence positive Mantoux inc. tuber	Incidence positive Mantoux exc. tuber	Incidence of tuber
White	869	51	23	5%	3%	2%
Black	131	16	9	12%	5%	6%
Total	1000	67	32	67%	35%	32%

TABLE IV—CLINICAL AND RADIOLOGICAL TUBERCULOSIS IN OUR SERIES

Distribution of tuber lesions	Tuber of lung (parenchymal—adult type)	Tuber of lung (childhood type—tracheo-bronchial form)	Tuber of lung (combined lung and tracheo-bronchial form)	Tuber meningitis
No. of cases	4	11	13	4

formed before a routine chest plate. For public health purposes in children, Mantoux tests should be performed routinely and then all positive reactors searched for signs of Koch infection.

The incidence of positive skin reactions (excluding tuberculosis) is practically the same in boys and girls—3.5 per cent in the former and 3.4 in the latter. The incidence of tuberculosis in our series was

3.5 per cent in males and 2.6 in females (Table II).

Drollet's³ incidence of positive Mantoux was thirteen per cent in females and fifteen in males. Webb² finds an incidence of 13.3 per cent in males and 15.7 in females. Myers⁴ and Chadwick⁵ in their series find the incidence slightly higher in males.

The total percentage incidence of positive Mantoux in our series was 5.9 per cent for white children and twelve per cent for black. Excluding the cases of clinical tuberculosis the percentages were 3.2 per cent in white children and 5.3 in the black (Table III).

The incidence of tuberculosis was 2.7 per cent in the white race and 6.9 in the black, thus the incidence relationship of positive Mantoux closely parallels the incidence percentage of tuberculosis. This is another extremely important routine reason for the general use of the tuberculin test since a fair estimate of the number of cases of clinical tuberculosis can be made from the percentage incidence of positive skin reactions in any community. The higher incidence of positive skin reactions in the black race has been noted by many. Drollet's³ reports 11.1 per cent positive in the white and 15.4 in the black.

Mantoux Reaction in Acute Infections

The percentage incidence of positive Mantoux tests in acute infections such as pneumonia, otitis media and upper respiratory infections is practically the same as the percentage incidence for the entire series excluding the cases of proven tuberculosis. Rheumatic heart disease and chorea show a higher percentage incidence of positive reactions. (However, these diseases occur in older children.) It is of great interest to note that in our series the percentage incidence in malnutrition and rickets is not higher than in the general group.⁶

These observations are not in accordance with Smith^{1,2} who believes that acute illness may suppress the Mantoux reaction. Drollet³ however presents two large series of cases one showing the positive reactors in three large Manhattan hospitals and the other the results of skin tests in various health clinics (Chart

I, curve C and D) Although the former group included a large percentage of children with acute illnesses and the latter a large group of children without acute illnesses, the incident rate of positive Mantoux was about the same in both groups. Our results and Drollet's observations suggest that the results of skin testing in acute illness needs further study.

The observation has repeatedly been made that the incidence of positive skin reactions is diminishing with the passing of years, as the death and registration incidence of tuberculosis decrease. Chart I is a complete chart of the surveys of positive skin reactions in and around New York City in different years. It graphically portrays the gradual fall of the percentage incidence in the different groups. Comparing the various curves, one sees a remarkable fall in the incidence of positive Mantoux through the years, and the unusually low percentage of positive reactions in our cases which can be explained by the generally noted fall of incidence, and also by the fact that earlier studies were made in Manhattan where the incidence of tuberculosis has been consistently higher than in Brooklyn where our studies were made. Drollet³ makes the following observation: "In 1921 the tuberculosis death rate of Manhattan was 130 per 100,000. In 1931 death was still 127 per 100,000, whereas in Brooklyn it had fallen from 87 to 51 per 100,000 or by 41% for the same years." In New York City in 1931 11,794 cases of pulmonary tuberculosis were reported with 4,370 deaths. In 1935, 8,796 cases were reported¹³ with 3,969 deaths.

It is a common knowledge that the incidence of tuberculosis and its result, positive tuberculin test, varies in different communities.

Chart II, a much-quoted table, has crept into many modern text books and articles. It is the basis for the general practitioner's erroneous concept concerning the Mantoux test, since the incidence of positive tests are so high that we learn little by performing it. The chart shows a rapid fall of incidence rates through the years. This observation must be qualified by knowledge that tuberculosis rates vary greatly in different communities.

In Chart I, we mentioned our 32 cases

of positive tuberculosis.* Table IV is included to show the distribution of the

*It must be remembered that these cases are from the children's medical service. Other forms of Koch infection, in K.C.H. go to Orthopedics, gu E.N.T., etc.

CHART I—MANTOUX REACTION IN NEW YORK CITY, 1921-1936

- A—6429 cases in eight tuberculosis clinics, over fifty per cent contacts. A large number of contacts makes this an unsuitable curve for comparison.³
 B—7668 cases in Bellevue Hospital¹ (New York City)
 C—6080 cases in three Manhattan hospitals.³
 D—1965 cases in health clinics.³
 E—Author's series—all positive Mantoux (1000 cases)
 F—Author's series—positive Mantoux excluding cases of proven tuberculosis (1000 cases)

CHART II—MANTOUX REACTION IN OTHER CITIES, 1909-1932

- A—Vienna⁹
 B—Philadelphia⁷ (2678 cases)
 C—Graz¹¹
 D—London⁸ (1003 cases—twenty-eight per cent contacts—1930)
 E—Minneapolis⁴ (2045 cases)
 F—San Francisco¹⁰ (3500 cases)
 G—Chicago² (1000 cases)

tubercular lesions. All these cases received the benefit of repeated x-ray studies and many were proved by the finding of the tubercle bacilli or at autopsy. *477 per cent of our positive Mantoux show clinical tuberculosis for all age groups.* Up to seven years of age, sixty per cent of the positive Mantoux were in clinically proved cases of tuberculosis. From seven to twelve, only twenty-nine per cent of positive skin reactions were in cases of tuberculosis.

Thus a child with a positive Mantoux should always be thoroughly examined for tuberculosis.

In 1920, the death rate from all forms of tuberculosis in the United States was 114 per 100,000. In 1933 this figure had fallen to 60 per 100,000. These figures show that definite progress has been made in the struggle against this dreaded disease. The lowering of incidence of tuberculosis is reflected in the lowering of the percentage rates of positive skin reactions. This diminution increases the importance of this simple diagnostic procedure and the adoption of its widespread use in general practice may mark the next step forward in the progress of what may be called the battle against the white plague—tuberculosis.

Summary

1 The results of a study of tuberculous skin reactions in 1000 admissions at Kings County Hospital are presented.

2 The age incidence of positive skin reaction has been shown.

3 The race incidence shows the colored race to contain about twice as

many positive reactors as the white race.

4 The incidence of positive reactions is equal in both sexes.

5 The falling rate of positive skin reactions from 1921 to 1936 for New York City has been graphically portrayed.

6 The results of Mantoux tests in different cities of the world show that the incidence varies greatly in different places.

7 A plea is made for routine tuberculous skin testing of children because of the simplicity of the test and the great diagnostic significance it has.

8 For economic reasons, Mantoux tests should always be done before routine chest plates (of children).

Acknowledgment

We are indebted to Dr. Paul L. Parrish and H. B. Logie for their assistance in establishing a cross card index based on the "Standard Classified Nomenclature of Diseases" which facilitated the gathering of these statistics.

'O, IS THAT SO?

The world has long been used to statesmen with brains of the "O" or zero type. Now a Japanese doctor has thrown the officials of Nippon into a panic by declaring that all diplomats should have "O" type blood. We can imagine the rush of agitated officials to the laboratories, and the deep silence when the blood turns out to be some other type. The news dispatch from Tokyo runs:

Dr. Tsunemasa Nugaki, medical adviser to the Foreign Office, urged the government today to pick its diplomats by blood type—the "O" kind.

Dr. Nugaki explained that there were four

distinct types of human blood, "A," "B," "AB," and "O." He added that only "superior" men like Prince Fumimaro Konoye, the Premier, who possesses "O," type blood, were fitted to fight Japan's diplomatic battles.

"These men combine level-headedness with quick, unerring decision, perseverance and a gentle mien cloaking an iron will," said Dr. Nugaki.

"Unlike fortune-telling, the blood type test is completely scientific."

"We no longer want pale, anemic, genius-type fellows in the government, but robust chaps who are vigorous and full-blooded."

The doctor's dictum created a sensation in government departments.

ANALGESIA AND ANESTHESIA IN OBSTETRICS

Pentothal Sodium, Cyclopropane, and Vinyl Ether

WESLEY BOURNE, M D, *Montreal*

It is an old problem—that of the relief of pain in obstetrics—and its solutions are still a subject of great controversy, which has been stimulated lately by the increasing demands of our women excited by the palpably specious assurances of some physicians and the active interests of drug houses. However, we must not cease to seek suitable measures of assuaging the suffering, that is without harm to mother or child. Indeed it is our bounden duty so to do. Let us abide by the common maxim, with end and aim to make abstruse things simple.

As a composite of experiences it is culled that of the many drugs which have been used in obstetrics for their analgesic and anesthetic effects, almost any of them may be allowed from dependable hands, but for more universal employment we must try to find those drugs which are least injurious.

Variable degrees of analgesia, amnesia or hypnosis may occur from the use of such substances as morphine, scopolamine, paraldehyde, or the barbiturates, and also from the inhalation of gaseous or volatile anesthetics, in low concentrations. The advantages are well-known, but at the same time we are fully aware of the unfavorable conditions which may ensue. I shall not discuss relative merits too exhaustively but confine my remarks more particularly to one of the newer barbiturates, namely pentothal, and to the newer anesthetics, cyclopropane and vinyl ether (vinethene).

Great expectations were engendered from the work of Irving, Berman, and Nelson¹ setting forth the benefits of nembutal. These have not been fulfilled, on the contrary there are many affirmations that even in combination with scopolamine, nembutal may cause such excitability as to necessitate the caging-in of the patient and the employment of a constant attendant. The one is not practical for ward cases, and the other is not

conducive to good obstetrics. What is more, frequently uterine contractions become definitely weakened, labor is prolonged, and the use of forceps is made indispensable. Again, often the infant is depressed to such an extent that extreme resuscitative measures are essential.

Pratt, Tatum, Hathaway, and Waters² have found that pentothal causes *no* *cicitement*, depresses respiration only in anesthetic doses, does not disturb the circulation, and that, as this drug is broken down rapidly in the body, it closely resembles the so-called controllable anesthetics. Accepting their report, MacPhail, Gray, and I³ proceeded to use this thiobarbiturate* in the early stages of labor. From 116 cases we find that there are no noticeable toxic effects on mother or fetus, that the maternal heart rate is invariably slowed, seemingly due to the lessened excitability, and that when the fetal heart rate is within normal limits it is not changed by pentothal, but should it be unusually rapid, it becomes somewhat reduced by this drug. All the infants of this series breathed spontaneously. With respect to the influence of pentothal on uterine contractions, the duration of labor is markedly shortened, an average of nine hours for primiparae and of 4½ hours for multiparae. Concerning excitement, the woman is quiet, cooperative, easy to examine, and does not need special attention. We believe that a woman does not really want to forget all about her childbirth and that from a psychical point of view it is better for her to remember something of her travail. She is no hedonist. As the drug under consideration does not produce a very pronounced degree of amnesia, we have latterly caused this to be enhanced by the administration of a small dose of scopolamine (grs 1/150 to 1/100 at the

*The Pentothal Sodium was kindly supplied to us by Abbott Laboratories

time of the first portion of pentothal. As soon as labor pains are definitely established, four grains of pentothal in capsule are given by mouth. One-half hour later three grains more are allowed and this amount is repeated at the end of one hour. Usually the patient becomes quiet, sleeps in between the contractions, and does as she is told willingly. Every half to one hour, two or three grains more may be given if the effects seem to be wearing off.

Perhaps the substitute sulphur in the urea part of barbiturates may remain, and former oxygen lose its post, perhaps so to settle a heated controversy.

One should take care sedulously not to overestimate the usefulness of any one drug especially among those which have for their chief action depression of the cerebral cortex, as at its best this structure possesses some functions with characteristics which easily become quite protean. Just as there is considerable choice among the so-called analgesics, so too there are several anesthetics which themselves are useful for analgesia. We have long known the benefits of nitrous oxide in this respect, how that if anoxemia is avoided it may be given intermittently during labor, starting quite early, without harmful effects. With the advent of cyclopropane⁴ it was found that an abundance of oxygen may be given with this gas and anoxemia is entirely out of the question. Furthermore, it has been shown that in dogs cyclopropane anesthesia does not damage the normal liver, even after repeated administrations, nor after long periods, that it does not increase the liver damage purposely produced by chloroform, nor impede the usual recovery of the liver from chloroform poisoning, even when the cyclopropane anesthesia is prolonged, and that it does not cause liver impairment in starved dogs even after a three hour period of anesthesia.⁶ Again while cyclopropane was being used in obstetrics,⁷ liver function tests were carried out in three normal cases and in one of eclampsia. Practically no dye was retained in the blood of the normal women after the administration of cyclopropane, and as the liver of the eclamptic woman was damaged to an extent of more than fifty-five per cent before delivery, the damage

was not augmented by cyclopropane, there being less than fifty per cent dye retention in her blood twenty-two hours after anesthesia. At this time cyclopropane was used to produce intermittent analgesia during each uterine contraction for varying lengths of time in a number of women. In each case the termination of labor was conducted under cyclopropane anesthesia, from which recovery was devoid of untoward effect to mother or child. Griffiths,⁸ one of the first to use cyclopropane, is convinced of its superiority over other anesthetics in obstetrics. Very recently, he, with Morgan and Eaman,⁹ have "compared 100 cases of caesarian section under cyclopropane anaesthesia with 100 similar operations under other types of anaesthesia, principally ethylene and ether, and report very marked improvement in the postoperative course of the cyclopropane cases, particularly in regard to the factors of vomiting and abdominal distention. There was no case of adynamic ileus in the cyclopropane series whereas this had previously been a serious and fairly common complication, and there was no maternal death in the cyclopropane series. The cyclopropane cases required an average of three days less hospitalization. It is presumed that less disturbance to bowel function and less uterine hemorrhage are the principal reasons for smoother convalescence following cyclopropane anaesthesia."

I believe that the salutatory feature about the use of cyclopropane in obstetrics is that an excess of oxygen is given with it.

So much for a brief consideration of the gases—nitrous oxide and cyclopropane—so much for their advantages in obstetrics, but they may not be administered by other than competent individuals. Allow me to warn against self-administration of these gases,^{10 11} that is, by the woman herself from a "fool-proof" machine. While the dangers of anoxemia have been known for a long time, it is of interest to note that very recently Courville¹² of the Department of Neurology, Los Angeles County General Hospital, in a monograph on "Asphyxia as a consequence of Nitrous Oxide Anaesthesia" has given an exhaustive account of his studies of the effects of this form

of anesthesia on the brain in a series of thirteen cases, nine of which terminated fatally. In these a critical examination of the cerebral tissues was made. Regardless of the circumstances, the clinical symptoms and the pathological findings are the effect of *asphyxia* and are not due to any toxic effect of the nitrous oxide itself. He gives a detailed account of the damage done to the cortical cells and points out that much of this is permanent. It is easy to see that there will be a considerable number of instances wherein severe disturbances may take place without fatality. Whereas *asphyxia* is quite out of the question in cyclopropane anesthesia, yet another equally serious consideration presents itself here, namely, that cyclopropane is an extremely potent drug producing anesthesia so rapidly that it is very difficult to recognize the stages of this condition. Perhaps enough has been said to show that although these two gases occupy positions of priority in obstetrical analgesia and anesthesia when properly used, yet their employment will not become universal.

It seems fair to say that at long last we have a substance which is safe for common use, this substance is vinyl ether (called vinethene). That it possesses anesthetic properties was first demonstrated by Leake and Chen¹³ in 1930. Later Leake, Knoefel, and Guedel¹⁴ found vinyl ether to be preferable to chloroform and ethyl ether. They declared that dogs are more easily anesthetized, recovery takes place more quickly, nausea and vomiting are less marked, and that there are no significant pathological effects on the various organs. Then Goldschmidt, Ravdin, Lucke, Muller, Johnston, and Rugh¹⁵ showed, among other things, liver necrosis in some dogs after prolonged vinyl ether anesthesia, but no liver necrosis in monkeys, as well as no untoward effects on respiration, the circulation, the liver or the kidneys after several hundred operations of a very varied nature on patients of all ages and conditions. It was then that it occurred to me that this drug might be appropriate for anesthesia in obstetrics. Accordingly it was applied in this capacity and the facts¹⁶ of the first administration of vinyl ether to parturient women show that it is easy to give and

practically harmless. Since that time additional studies have been made and reported¹⁷⁻²⁰ so that now with confidence vinyl ether may be said to be "particularly suitable for obstetrical analgesia and anaesthesia in general practice on account of its safety for mother and child, its ease of administration, the rapidity of its action, the satisfactory maintenance of any desired degree of narcosis, and the early uneventful recovery."

The additional studies mentioned above, included those on the liver,¹⁷ from which it was found that vinyl ether anesthesia in normal dogs does not alter the liver function appreciably, it does not enhance the liver function damage produced previously by the inhalation of chloroform nor does it delay the period of recovery from this damage, and that its effects upon the liver function in partially starved dogs is not appreciably different from that produced in normal animals. These findings have been confirmed separately by Molitor²¹ and by Goldschmidt, Ravdin, and Lucke,²² each of the two sets of research being conducted differently from each other and from ours. Additional studies¹⁸ gave, as well, a most striking comparison between the liver function test findings following vinyl ether anesthesia in parturient women and those after chloroform administered under identical circumstances. There was dye retention in the chloroform cases, indicating definite liver damage, while the administration of vinyl ether was followed by very slight dye retention and consequently practically no liver impairment.

From experiments on lower animals Molitor has shown that mixtures of vinyl and ethyl ethers may have certain advantages. Accordingly we²⁰ were led to their employment in obstetrics and can recommend the mixture of twenty-five per cent vinyl ether with seventy-five per cent ethyl ether to be given by the "open" method. In this manner analgesia is attained, at least from a practical prospect, just as quickly as it is with vinyl ether alone and the usual disadvantages of ethyl ether induction of anesthesia are abrogated. This solves the problem of tremendous waste from rapid volatilization which occurs when vinyl ether alone is used by the "open" method. Hence the utility of an *improved ether* in obstetrics

for the general practitioner, made easy of application, relatively inexpensive, and quite safe—i.e., in comparison with chloroform or ethyl ether by itself. Although we have given this mixture through a simplified apparatus (made specially for vinyl ether by the Foregger Company of New York City) which consists of a closed system, fitted for supplying oxygen and for absorbing carbon dioxide, it is hardly necessary to use vinyl ether as part of a mixture in this fashion, for the simple reason that with a "closed" machine one is not concerned with the question of volatility. Notwithstanding all this, the fact still remains that it is infinitely better to administer this drug with oxygen. One cannot em-

phasize too much the advantages of giving oxygen with anesthetics, especially in obstetrics

Conclusions

I would at the present time recommend pentothal sodium for the early part of labor, then, from competent hands, nitrous oxide and oxygen for intermittent analgesia should the pains become severe, and cyclopropane anesthesia for the final stages

For those who are less experienced and for the general practitioner, vinyl ether is highly recommended to produce analgesia and anesthesia following the use of pentothal

THE VALUE OF SNUFF TAKING

The practice of snuff taking has declined greatly in England. It was at its height in the eighteenth century and continued down to the middle of the nineteenth, when it fell away. Letters in the *Times* from Sir Buckminster Brown (a retired urologist and a Surgeon) advocating snuff taking as a prophylactic against colds in the head has revived interest in the subject and led to a paper on it, which was read by Dr. J. D. Rolleston before the Society for the Study of Inebriety. As told by the London correspondent of the *Journal of the AMA*, he said that he habit, which once was in vogue in court circles, seemed likely at one time to find its last refuge in infirmaries and mental hospitals. He suggested that one reason for its disfavor was the great objection of Queen Victoria to any one sneezing in her presence. Sir Buckminster Brown

told the society that his experience with the virtues of snuff dated from his early days in practice when, after operations more or less continuously until the afternoon, when he had to start on his car-freshening and useful. He attributed his immunity from colds in the head to the action of snuff in stimulating the nasal mucous membrane and producing a flow of mucus. Pepper and other irritants would of course also induce sneezing, but tobacco snuff was more than an irritant. It was agreeable to most people, stimulating at first and then narcotic and astringent to the mucous membrane. His advice to the audience was "If you think you are sickening for a cold in the head, take a good pinch of snuff before going to bed and a pinch of snuff quite well in the morning," you will awake

TELANGIECTASES OF THE BRAIN STEM

Associated with Obstructive Hydrocephalus and Mental Deterioration

CHARLES DAVISON, M D and CHARLES ROSENHECK, M D, *New York City*
From the Neurological Service of the Hospital for Joint Diseases, and the Neuropathological Laboratory of the Montefiore Hospital

Telangiectases may accidentally be found in the central nervous system, especially in the pons and medulla oblongata, but rarely do they give rise to clinical symptoms. According to Virchow,¹ the floor of the fourth ventricle is a favorite site for these small, non-fully formed vessels commonly found in the skin or mucous membranes. Cushing and Bailey² found only one case of telangiectases with neural signs from a collection of 2,000 verified tumors of the central nervous system. The accidental discovery of these dilated channels in the floor of the fourth ventricle and near the iter in a case without localizing signs which led, however, to a picture of a progressive mental deterioration not unlike dementia paralytica or Alzheimer's disease, warrants this report.

Report of Case

E V P, a woman, aged fifty-eight, was admitted to the Hospital for Joint Diseases on March 25, 1934 with a history of generalized weakness for about five years. One year prior to her death she became bed-ridden and showed marked memory defects. The Wassermann of the blood at this time was negative, that of the spinal fluid was positive. She received extensive antisiphilitic therapy, without benefit.

Upon admission to the hospital she showed evidences of severe mental deterioration characterized by gross memory defects. The clouding of consciousness became marked just before exitus. Orientation was markedly disturbed in all spheres. She confabulated a great deal and had grandiose ideas. The neurological status revealed equal pupils which reacted sluggishly to light and well in accommodation. There were no extracocular palsies. The fundi oculi were normal. A right-sided facial palsy of the central type and dysarthria were present. There were flexion contractures in both upper and lower extremities. The deep reflexes were hyperactive, the abdominal reflexes were absent, a Babinski toe sign was present bilaterally. There were no gross sensory

defects. There was incontinence of both sphincters.

The Wassermann of the blood and spinal fluid was negative. The spinal fluid was clear, came under normal pressure, contained four cells, and its protein content was normal. The routine examination of the blood, urine, and blood chemistry was normal. Because of the poor condition of the patient, encephalographic study was not performed. An irregular temperature, varying from 99 to 104° F, was noted during her eighteen day stay in the hospital. The terminal picture was one of semistupor, respiratory and cardiac insufficiency.

Autopsy As the findings in the other organs had no bearing on the case, only those of the central nervous system will be reported.

Gross examination *Central nervous system* The frontal convolutions were slightly atrophic, more on the left. The cerebral vessels were normal. The brain was cut coronally. There was marked dilatation of the entire ventricular system with shrinkage of the white matter (Fig 1-A and B). The ependyma of the lateral ventricles contained numerous verrucae. The aqueduct was obstructed by dilated vessels situated on its floor and lateral walls (Fig 2-A and B). A needle passing from the aqueduct to the posterior part of the third ventricle could barely go through. Similar engorged vessels were noted in the floor of the fourth ventricle (Fig 3-A and B). The medulla oblongata at that level had a slightly lacunar appearance. *Spinal cord* The dura was normal. There was a slight translucency of the spinal cord in the cervical and dorsal regions. Sections from all cortical convolutions, corpus callosum, the pons, and medulla oblongata in the region of the aqueduct and fourth ventricle were embedded and stained by the mvelin sheath and cresyl violet methods. Frozen sections from the cortical convolutions were stained by the Bielschowsky and Sudan III methods.

Microscopic examination Sections from the frontal cortex disclosed a slightly thickened pia-arachnoid. The gray matter appeared thinned-out. The cortical cyto-architectural layers had a normal arrangement. Occasionally some ganglion cells stained

Read before the New York Neurological Society February 2 1937

Fig 1-A Dilatation of anterior horns of lateral ventricles, shrinkage of white matter, and slight atrophy of cortical convolutions

Fig 1-B Dilatation of lateral and third ventricles, shrinkage of white matter, and atrophy of cortical convolutions

poorly. The microglia cells were slightly increased in number. The cortical capillaries were hyperemic. In the white matter, there were numerous vacuoles, swollen oligodendroglia cells, and slight proliferation of the astrocytes. The other cortical convolutions showed similar changes. Occasional calcific deposits were found around the vessels of the motor cortex. Senile plaques or Alzheimer fibrillary changes in the nerve cells were not found. Sections from the corpus callosum disclosed slight fragmentation of myelin, swollen oligodendroglia cells many of which were arranged in rows, numerous vacuoles, and a few gemästete glia cells.

Sections through the aqueductal region revealed dilated vascular channels (Fig 2-A and B), which were lined by a single or several layers of endothelial cells surrounded by collagenous tissue. The lumen was distended and filled with red blood cells. The aqueduct was constricted and only partly lined by a single layer of ependymal cells. The nerve cells in this vicinity did not show pathologic changes, those of the locus caeruleus did not contain the abundant iron pigment normally seen. A few dilated channels

were noted in the pons, these, however, did not reach the size of those near the aqueduct. In the myelin sheath preparation, a few vacuoles and an occasional disintegrated fiber was seen in the pyramids.

Fig 2-A Section through aqueduct of Sylvius showing partial obstruction of aqueduct and dilatation of blood vessels

Fig 2-B Same as Fig 2-A. Cresyl violet stain $\times 60$

In sections through the brain stem, the fourth ventricle was constricted and distorted and in its floor there were several dilated vascular channels filled with blood (Fig 2-A and B). The histologic structure of the walls of these channels was the same as in those from the aqueductal region. There was also a dilated blood channel between the cerebellum and the pons at the upper border of the right brachium pontis. A similar solitary dilated vessel was seen between the floor of the left brachium pontis and the cerebellum. Insignificant nerve cell changes were found near these telangiectases. The Purkinje and other cells of the cerebellum were normal. Some of the ganglion cells of the hypoglossal nuclei showed pigment atrophy. The perivascular spaces of one vessel in the medulla oblongata contained inflammatory cells. Sections of the medulla oblongata through the twelfth nerve nucleus disclosed a moderate dilatation of some of the venous channels.

Spinal Cord A slight paling of the columns of Goll was noted throughout all the spinal segments. Some of the myelin sheaths were slightly fragmented, variations in size were also noted. Numerous astrocytes and glia fibers were found in these areas. In the Sudan III preparation, small deposits of fat were found in the slight areas of degeneration.

Comment

The mental picture in this instance simulated a number of neural disorders such as Alzheimer's or Pick's disease, dementia paralytica, and frontal lobe neoplasm. In retrospect, a correct localization might

have been made if a ventriculogram or encephalogram had been done. Clinically, dementia paralytica was ruled out when the examination of the Wassermann of the blood and spinal fluid was negative.

The presence of the dilated vascular channels in the region of the floor of the fourth ventricle and aqueduct of Sylvius and the constriction of these cerebrospinal channels led to the obstructing hydrocephalus and the resulting mental picture. Histopathologically, the absence of marked cortical atrophy, of distortion of the cortical cytoarchitectural layers, of senile plaques, of fibrillary changes in the nerve cells or of the chromatolytic nerve cells were sufficient to rule out a diagnosis of presenile psychosis (Alzheimer's or Pick's disease). The histopathologic changes in the cortex and white matter such as the slight proliferation of the pia-arachnoid hyperemia of the cortical vessels, slight pallor of the cortical nerve cells, increase

Fig 3-A. Section through fourth ventricle showing distortion of same and several dilated venous channels on its floor.

Fig 3-B. Notice dilated vascular channels on floor of fourth ventricle, obstructing same.

in microglia cells, slight degeneration of the myelin in the white matter and corpus callosum, swelling of oligodendroglia cells, and of the vacuoles are typical changes seen in increased intracranial pressure. We are, however, unable to explain the slight pathologic process in the columns of Goll.

The telangiectases of the skin or the mucous membranes, especially the familial types, first pointed out by Osler, are known to cause symptoms more frequently than those of the central nervous system.

Fig 4 Telangiectases in floor of fourth ventricle from a case without neurologic signs

These dilated vessels, which are frequently found by accident in the brain stem, are symptomless (Fig 4). Instances in which they produce neurologic signs, as indicated in Cushing's and Bailey's² collection of 2,000 verified tumors, are very rare. These cases, we believe, are worth reviewing briefly.

Cushing's and Bailey's patient, a psychoneurotic, after a radical mastoidectomy, developed attacks of prolonged unconsciousness with symptoms suggesting arachnitis or a posterior fossa tumor. Following a negative suboccipital operation, the attacks of unconsciousness, except for one or two, ceased for eight years. Then she suddenly experienced a severe headache, became comatose, and died. At autopsy, telangiectases in the

pons and medulla oblongata were found. A somewhat similar case, familial in character, was reported by Kufs.³ He described multiple telangiectases of the skin in a man who died suddenly at eighty-one. At autopsy these capillaries were found in the cerebral hemispheres, pons, and liver. A daughter of this patient suddenly developed an alternating hemiplegia. Kufs concluded that the paralysis was possibly due to a hemorrhage from pontine telangiectases. It is easily conceivable that these thin vessels may rupture when they become distended with blood. In the skin, rupture of such vessels may lead to a diagnosis of a so-called form of "pseudo-hemophilia." Weber and Harris described "nervous attacks" in a woman thirty-four years of age, these consisted of giddiness, unsteadiness in gait, tendency to fall to the right, diplopia, difficulty in walking, tingling sensation, and a left supranuclear facial

The authors believed that the most probable explanation for these attacks was a capillary telangiectatic condition of a portion or portions of the cerebral leptomeninges as a result of extravasation of blood from these abnormal capillaries. Larabee and Littman,⁶ in reporting hereditary hemorrhagic telangiectasia in a family of five, found one member who had a "nervous break-down" followed by a complete bilateral ophthalmoplegia externa. An autopsy was not performed, but the authors believed that telangiectasis of the midbrain was the most likely cause for the ophthalmoplegia.

It is necessary to differentiate telangiectases from angiomas and hemangioblastomas, which are true malformations. Histopathologically, as seen in our instance, the dilated vascular spaces in telangiectasia are usually lined by a single layer of endothelial cells and surrounded by a few collagenous fibers, the intervening tissue between the vessels is normal neural tissue. In angiomas, the walls of some of the tangled vessels may be fully-formed, they are usually tortuous, and the vessels are separated by intervening glial tissue. In hemangioblastomas, the vessel walls are not fully-formed, they may be lined by one or several endothelial layers as in the telangiectases, but the intervening tissue between the blood vessels is formed by xanthoma and endothelial cells.

As these cases are rarely recognized clinically, little can be said about the treatment. In the presence of obstruction or other localizing signs, intracranial exploration is advisable, and in the absence of brain tumor, deep x-ray remains the only form of treatment.

Conclusion

Telangiectases of the brain stem obstructing the fourth ventricle and aqueduct of Sylvius led to a picture of pro-

gressive mental deterioration simulating dementia paralytica or presenile psychosis

WHEN THE OXYGEN THINS OUT IN THE SKYWAYS

A sweeping refutation of the theory jointly attributed to him and Dr. Alvan L. Barach, of the Columbia-Presbyterian Medical Center, in recent issues of scientific and popular magazines that oxygen starvation seriously impairs the judgment of pilots flying above 10,000 feet and may have caused many of last winter's air line crashes, was made by Dr. Ross A. McFarland, assistant professor of Harvard University's fatigue laboratory, before the ninth annual convention of the Aero Medical Association of the United States at the Waldorf-Astoria.

Dr. McFarland's views, set forth in a paper on "Physiological and Psychological Effects of Low Oxygen on Normal Man," which he prepared in collaboration with Dr. D. B. Dill, associate professor of industrial physiology at Harvard, were based upon scientific observations and laboratory tests made on the crew of Pan American Airways' China Clipper during a round-trip flight across the Pacific last summer.

He reported that, although the ship flew constantly at heights of 8,000 to 12,000 feet during the 140 hours, his aerial experiments were under way, the crew "maintained high mental and physical efficiency" throughout the trip. The earlier experiments on which Dr. Barach and Dr. McFarland chiefly based their findings were conducted in de-compression chambers and with other laboratory equipment designed to reproduce artificially the decreased atmospheric pressures and rarefied air encountered in high-altitude flying.

Dr. McFarland attributed the mental alertness and physical fitness of the clipper's crew throughout the long ocean flight to the fact that they had become "acclimated" to high-altitude conditions besides standing regular "watches" and getting frequent rest periods. He said later, however, that he made tests on himself and the assistant who accompanied him without

detecting any impairment of mental or physical functions and conceded that any normal passenger probably would experience no discomfort or unusual sensations when flying for long periods at such altitudes.

One result of his "flying laboratory" tests, Dr. McFarland said, was the discovery of a ten per cent increase in the red blood cells of the clipper's crew while aloft. This increased the oxygen-carrying content of the blood, he explained, and helped compensate for the thin air those aboard the plane had to breathe.

Dr. McFarland also said a series of laboratory tests at Harvard had established that it is possible to increase by 5,000 or 6,000 feet the "ceiling" at which any pilot retains his full mental and physical faculties through introducing three per cent of carbon dioxide into the air mixture he breathes. He said the gas acts as a stimulant to the respiratory system, this proportion doubling the normal rate of breathing and thereby causing the blood stream to receive a greater supply of oxygen in a given time than it ordinarily would in the rarefied upper air.

Dr. Barach, who participated in the formal discussion of Dr. McFarland's paper, insisted that airmen flying at altitudes of 10,000 to 12,000 feet suffer from recurring oxygen want and should have this life-supporting medium supplied to them artificially. He advocates changing the present Bureau of Air Commerce regulation requiring air liners flying above 15,000 to carry oxygen equipment for crew and passengers so that such installation would be mandatory at 10,000 feet.

"We do not argue that garage mechanics should be 'acclimated' to carbon monoxide fumes we take steps to protect them from this danger," Dr. Barach said. "I think pilots should be protected in the same way from oxygen starvation."

BED REST FOR BACK INJURIES

EDWARD T WENTWORTH, A.B., M.D., F.A.C.S., Rochester

From the Department of Surgery, Division of Orthopedics, University of Rochester School of Medicine and Dentistry

There is a fairly strong opinion on the part of those physicians and surgeons, who know end results as determined by employee's time lost and employer's money spent, that arthrodesing operations on spine and pelvis are both expensive and ineffective *Nihil nocere*

The following quotations are excerpts from unpublished reports given by the chief surgeons of large insurance companies

"It is difficult to evaluate the final results, but it does seem as though in the treatment of injured backs, we are no nearer a solution than we were a number of years ago"

"I am free to admit that we are often undecided as to the proper course to pursue in these back cases. As a matter of fact 75% we compromise without resort to any operative procedure, and settle them for a lump sum"

"One method of treatment is just as good as another. It would appear that there is no choice"

"Following an observation of 15 years in the diagnosis and treatment of low back conditions, it is our opinion that, with a few exceptions, conservative treatment has shown better results than operative treatment"

Unquestionably, there are correct indications for operative procedures. The orthopedic surgeon will establish slowly, by trial and error, these indications. But, until that has been better done, operative enthusiasm stands as a definite menace to industry, employer and employee alike. In the meantime, many thousands of workmen annually need treatment for back injury, and, a few thousand doctors have the responsibility of rendering that treatment.

It is almost axiomatic that all *minor* injuries of the back will recover with little else than immediate and proper rest, adequately prolonged. All *major* injuries of the back require immediate bed rest.

Therein lies the importance of discussing how to put a man to bed.

Bed support must be given immediately after injury, not after the injured has tried to carry on his job for a few days. It is better economy for an occasional workman to lose, unnecessarily, a few days work than for many workmen to lose several months work, when one month, immediately after injury, would have sufficed.

In bed, the back must be so supported as to make protective muscle spasm unnecessary. Add morphine for a day or two if there is much pain. Only rarely is the form of any part of the back altered by injury. The change is chiefly in altered function. If muscle fibers or ligaments are torn, or pulled away from their moorings in and beneath periosteum, a new protective muscle function is immediately instituted to prevent continuation or repetition of the original traumatizing motion. This protective function persists until no longer needed, i.e., until proper and adequate rest conditions are provided. If this protective muscle function is not soon replaced by proper outside support, it becomes a source of pain and disability in itself.

We recommend this general position (Fig 1) of thigh and leg flexion as the best for muscle and ligament strain about the lumbar spine and pelvis. It is not correct for fracture of bodies of vertebrae or of intervertebral disks, but is good for fracture of articular processes.

With boards under a firm mattress at back and thigh levels the semi-sitting position provides adequate support for injured articulations and ligaments in a position of maximum muscle neutrality, i.e., a position in which there is a minimum tug on injured joints by muscle tonus, hence, a minimum of protective muscle spasm.

The skeletal parts in these drawings

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 26, 1937

are plantograph enlargements of photographs of a skeleton, the separate bones of which are joined together with rubber, applied in liquid form, about articulations, to simulate ligament. Measurements were taken on the articulated skeleton, not on drawings. As a rule thirty degree elevation of torso and thigh proves the most comfortable position for the patient in severe pain. The flexed position measurements were made at those angles. In practice, the patient is permitted to choose the amount of elevation most comfortable.

In changing from the flexed to the extended position the distances traversed by the sartorius and tensor fascia femoris muscle-tendon combinations (AS and AT) increase from 44.5 to 50.8 cms, an increase of fourteen per cent. That means, in the extended position, a strong downward pull on the anterior superior spine which is accompanied by rotational stress on the sacroiliac joint. If that joint is inflamed or its ligaments injured, an immediate protective muscle spasm is instituted—a contraction of the hamstrings which may institute sciatic pain, and of the quadratus lumborum which may institute back pain.

Likewise, the course of the rectus femoris from the anterior inferior spine (R) to the patella (F) is lengthened in the extended position from 37 to 40.8 cms, an increase of ten per cent. Even

the course of the hamstrings (BF) from the tuberosity of the ischium to the upper posterior leg is increased in the extended position from 35.5 to 37.2—a five per cent increase. In other words, all of the thigh musculature acting on the rotational sacroiliac motion is placed in a position of relaxation by the flexed hip and knee position.

In the extended position also the psoas magnus is stretched.

	Flexed	Extended	Increase	Increase
1st lum. to lesser tro	30 cms	31.8 cms	1.8 cms	} 7%
2nd lum. to lesser tro	27	28.5	1.5	
3rd lum. to lesser tro	24	25.5	1.5	
4th lum. to lesser tro	21	22.5	1.5	
5th lum. to lesser tro	18.5	20.5	2.0	

This produces an elevating force on all lumbar vertebrae tending to raise the spine from support of the bed and aggravating inflamed spinal and lumbosacral articulations.

Much of the back pain in spinal arthritis is due to muscle spasm. It is largely eliminated by rest and local heat, i.e., the pain goes when the spasm is released. Only exceedingly rarely does one find any increase in the size of osteoarthritic changes following injury. Such changes, undoubtedly, make the joints and ligaments involved more vulnerable to injury because they limit flexibility. They reduce the range of joint motion during which muscle action can absorb the force of trauma. And they are in the way to receive the unabsorbed shock of trauma.

Fig. 1

Fig 2 Position of lower lumbar articulations, patient lying supine in sagging bed

But, when injured, they heal, as does any injured tissue, if kept quiet and supplied with blood. It is not rational, then, to conclude that a joint, found after injury to show the degenerative arthritic changes of subchondral density and marginal proliferation, must be permanently deprived of its motion. Sir Arthur Keith said of John Hunter that the most important contribution he ever made to surgery was "his clear recognition of the fact that restoration is effected by powers inherent in the living tissue of the patient."

Moreover, if this protective muscle function, this spasm, is not soon released, it produces an altered position at articulations where healing processes are going on (Fig 2-3). That results in unnecessary scar limitation of motion and prolonged discomfort during the convalescent period. Such pain the patient does not differentiate from the original pain of injury. He develops fixed ideas of permanent disturbance, and fear to institute the motion needed for recovery.

For example, if the capsular ligaments of this articulation between fourth lumbar and fifth lumbar are torn, and the spine is permanently held in lordosis by a prolonged supine position in bed, healing results in scar which makes straightening or flexion of the lumbar spine painful, at least for a time. The patient will admit that he feels pretty well sitting or standing, but will complain that he cannot stoop over at all. Or, if during the healing period, the patient lies supine in a sagging bed, scar makes uncomfortable the normal lordosis in erect position and the patient will want to wear a brace for a long period of time.

Fig 3 (Upper) Position of lower lumbar articulations, patient supine, lower extremities extended producing forward rotation of pelvis and upward lift upon lumbar spine by psoas magnus. (Lower) Neutral spinal position obtained by flexing thighs and knees.

While these photographs show extremes of joint position they do not show exaggeration of joint position. If one uses the relative proximity and separation of the spinous processes as an index of the change at articulations, it will be noted that in film of this normal, thirty-five year old male, assuming, under active motion only, positions of lumbar lordosis and kyphosis, the changes are not greater than in the articulated skeleton. One must remember that ligament strains occur at the extremes of normal motion, for it is only at the extreme that ligaments come into restraining function.

The back must be so supported as to prevent gravity strains on all spinal ligaments. Nature never uses ligaments for continuous support of parts or for the continuous active maintenance of parts in position. Nature uses ligaments as secondary supporting mechanisms, final safeguards against abnormal joint motion,

BED REST FOR BACK INJURIES

but always secondary to the active and primary force of muscles. Muscles only have active elasticity. They contract and elongate with continuous tonus. Ligament has no elasticity, only the capacity to maintain tension when passively tautened. Ligament subjected to continuous tension invariably elongates. It also produces pain when its osseous attachment is long held under tension. The back must be so supported as to prevent compression of injured vertebral bodies, intervertebral disks or articular surfaces.

The question of pressure upon spinal nerve roots at the foramina of exit from the neural canal has not been settled well enough for any dogmatic statements. There would seem to be ample space for the nerve in any spinal position. One can readily show that the size of the foramen is larger with the lumbar spine flexed than with the lumbar spine extended. One can accept that the posterior primary division of the spinal nerve winds closely over the ligamenture of the joint and that any inflammation of the joint may institute radiating pain, but that there is direct pressure upon the nerve roots appears improbable.

So far, we have dealt only with providing the proper support to give the back rest (Fig 4). That is the first

phase of treatment. The second, and equally important one, is to provide the means for motion. Putting a man to bed with adequate and proper support for his back so as to attain the objectives enumerated does not mean entire elimination of motion. Absolute rest is merely an imaginary state. Moments of quiet are always alternated with moments of motion. Motion preserves the active function of muscles. Nature will institute motion automatically, beginning with very small motions, and will gradually increase it, if the parts are adequately supported during the intervening periods of rest. These early motions are involuntary, in the sense that the patient does not wilfully perform them. There is no consciousness of these motions unless they are painful. These small motions are reflex responses to the small discomforts of prolonged single position, of too much heat or cold, or a fold in the sheet, gas in the intestine, etc. They are not always possible in plaster-of-Paris casts. They are inhibited if the support is such that they are painful.

There is also a large psychic element involved in this ability to enjoy small automatic movements. Any patient responds better to any form of treatment if he is comfortable during it. The more ignorant the patient, the more this is true.

Fig 4

Fig 5

Comfort is secured by position, by environment, by the presence of friends and friendly surroundings. Comfort in bed is necessary for sleep. The bed patient does not do enough to get tired. Nevertheless, he demands sleep to escape from disagreeable cerebral experiences. Ability to make the patient comfortable, to put the ignorant patient into a vegetative state, constitutes good nursing and good doctoring too.

Proper bed rest soon becomes manifest because small involuntary movements merge into voluntary, purposeful movements (Fig 5). The patient will be found squirming around, reaching for things, stretching his extremities, and every time he does that he is exercising

his back and approaching convalescence. He should be encouraged in such endeavors but usually not urged vigorously to institute them. If he finds that he is not going to be driven, but is going to be allowed to go his own pace, no matter how slow it may be, he will get well quicker. If, on the other hand, his physician begins to talk about light work in a week or two, when he still has pain turning over in bed, he will certainly rebel. His defensive mechanism begins to control his behavior. Fusion operations are not designed to immobilize the emotions. Their effect, unfortunately, is often to actively mobilize the emotions.

PROFESSIONAL BLDG

NEW RULES FOR SCHOOL HEALTH

New regulations for the health and physical education program in the public schools of this state have been adopted by the State Department of Education and announced by Dr. Hiram A. Jones, Director of the Health and Physical Education Department. Their aim is to prevent physical, mental and social handicaps in young persons. They are now effective, except the section on athletic contests, which goes into effect next fall. All the pupils will be expected to take part in athletics of some kind.

Further, the educational authorities must give primary consideration to the well-being of individual boys and girls in the conduct of games and sports, and conduct all activities under adequate safety provisions. Athletic activities are to be made an articulate part of the physical education program under the supervision of the professionally trained physical education staff.

"It shall be the duty of boards of educa-

tion," the regulations say, "to sacrifice no individual for the sake of winning events, to equalize in so far as possible the powers of opponents in individual and group athletic competitions, to provide adequate health examinations before participation in strenuous activity and periodically throughout the season, and to permit no pupil to participate in such activity without the approval of the school medical officer."

Girls' activities are limited to club athletics, intramural games, play days and approved invitation contests. All such games are to be conducted under girls' rules with women acting as referees, umpires or officials. Wherever possible, girls' contests are to be conducted under the supervision of a woman physical education teacher.

"These rules will prevent the exploitation of girls who have been used in some schools for the purpose of increasing gate receipts," Dr. Jones said.

BLIGHTED BUDS

Not every flower that in God's garden grows
May boast the beauty of a perfect rose,
Nor can all children borne on nature's tide,
Adjust their pace to life's quick-changing
stride

With grateful hearts, we count the sound
and strong,
The fortunates who ever forward throng
If wisely guided, these will surely find
The luscious fruits that feed the healthy
mind

But blighted buds must have more skillful
care

Presenting problems deep and lesions rare
'Tis these that science nobly strives to heal,
'Tis these with whom the world must kindly
deal

Let no one dare to say "There is no cure,
And buds that bear the blight must blight
endure"

Tomorrow's sun may bring a brighter glow
To many who today but darkness know—

DUDLEY MATTICE, *Mental Hygiene News*

TANNIC ACID THERAPY IN ALLERGY OF THE NASAL MUCOSA

HAROLD A. ABRAMSON, M.D., *New York City*
From the Medical Service of Dr. George Baehr, The Mount Sinai Hospital

Introduction

Tannic acid has been employed for many years as an astringent in ocular and nasal therapy, especially in the form of the glycerite. Apparently it has not been employed to an appreciable extent in allergic conditions of these organs. That solutions of tannic acid may be of service in preventing or diminishing symptoms of probable allergic origin was suggested to the writer by the results of its use in a patient who was hypersensitive to brazil nuts. This patient's sensitiveness was so great that "swelling of the throat" occurred if "cake cut by a knife that had previously been used to cut a cake baked with brazil nuts" was ingested. Swallowing a small amount of a solution of tannic acid allegedly relieved the unpleasant symptoms. The writer has not as yet developed this phase of the subject as part of tannic acid therapy in oral allergy but has rather used it in certain types of allergic conditions of the nasal mucosa. The recognition that certain astringents like tannic acid and alum administered intranasally might prevent poliomyelitis has emphasized the possibility that local measures may hinder the passage of certain large molecules like viruses or proteins through the nasal mucosa. Astringents of this type could react on the nasal mucosa on excitants or on both simultaneously in cases allergic in nature.

Olitsky and Cox¹ in 1934 demonstrated that mice which had received nasal instillations of tannic acid (or alum) were resistant to infections with equine encephalomyelitis administered by the nasal route. Further investigations by Sabin, Olitsky, and Cox² showed that tannic acid instilled intranasally over a period of several days protected monkeys against the virus of poliomyelitis by the nasal route. One half per cent tannic acid protected mice but three per cent was required for monkeys. Treatment over a period of three days was required to induce resistance. The effectiveness of the action of the tannic acid was apparently not on the

virus itself but rather on the tissues of the host, possibly the nasal mucosa. These authors also showed that four per cent tannic acid can be given to human subjects with only slight discomfort and no obvious harmful effects.

Olitsky and Cox have shown that the absorption of Prussian blue through the nasal mucosa of rabbits and mice may be retarded after intranasal treatment. Rake and Cox³ found that tannic acid may produce an inflammatory reaction in mice and that a qualitative difference in the manner of passage of dye occurred through the olfactory mucosa. A correlation also existed between the degree of mucosal inflammation and the passage of the dye. In six mice in which pigment was observed to a lesser extent, the inflammatory process was relatively greater. In three other mice the tannic acid treatment produced a lesser inflammatory response with a correspondingly slight increase in the passage of pigment into the olfactory cells. Rake⁴ has more recently analyzed these phenomena⁵⁻⁷ in detail.

Case Reports

The writer has been employing chiefly one-half per cent tannic acid in certain types of allergic rhinitis since 1935. The following case reports will instruct the reader in its use.

CASE 1. A twenty year old medical student registered for the physiology course at Cold Spring Harbor in June 1935. The dormitory building as well as many of the laboratories was closed during the winter. He was constitutionally allergic and especially sensitive to dust, and on taking up residence at the laboratory began to have attacks of sneezing and coryza severe enough to prevent attendance at lectures and laboratory. The bedroom was changed and cleaned thoroughly. New pillows and a mattress were purchased with no cessation of symptoms. A three per cent solution of tannic acid was suggested. This was used by the patient as a spray on arising and several times during the day. It was slightly irritating but after sneezing several times the nasal symptoms

diminished sufficiently to enable him to work.

This medical student analyzed his case carefully and summarized his experience as follows

(a) Glycerine solutions of tannic acid leaked out of the nostrils and the treatment afforded no relief

(b) If an aqueous solution was sprayed into the nose three or four times daily an important effect was observed after three days. The treatment had to be kept up continuously. If it was omitted for a period of days the attacks of sneezing returned. If the spray was used continuously with the formation of crusts in the nose (probably protein tannates with a superimposed film of tannic acid) the results were unusually good. Under these conditions there was no sneezing at all irrespective of exposure to the same dust. But even if the crusts had formed, discontinuance of treatment for any considerable length of time led to a recurrence of the sneezing attacks. After leaving the laboratory this form of therapy was discontinued, since no sneezing occurred in the new environment. This case was one of extreme hypersensitiveness to dust. The patient was unable to attend classes or work without therapy.

CASE 2 E W, Finnish born woman of forty-eight years had had hay fever for twenty years and asthma for fifteen years. She was sensitive to wool, cotton, and silk, and it was necessary to stop wearing and handling these substances. Intradermal tests with the usual inhalants showed positive reactions to ragweed, timothy, dust, glue, and wool. Food reactions were essentially negative. The patient's clinical reactions were quite marked, however, to dusts, paints, and sharp odors. In March 1936 she complained of itching eyes which were somewhat relieved by drops of an aqueous solution of $\frac{1}{2}$ per cent tannic acid twice daily. At this time the patient complained of sneezing while dusting her home and the same concentration of tannic acid was used in a spray twice daily and before dusting. During the grass season she continued using the spray for the relief it afforded and in addition received injections of dust, timothy, and ragweed extracts. On August 17 her home was repainted. She had no complaints in spite of the fact that she lived at home during the painting. In the previous year she had had hay fever and asthma. Under the combined therapy of pollen and dust injections with tannic acid intranasally she was able to perform all of her duties as housewife and again was able to iron silks. She passed through the ragweed season (1936), which had a higher pollen count than the previous one, without any symptoms of hay fever. At this time (February 1937) she is still using $\frac{1}{2}$ per cent tannic acid solution as a spray without any obviously harmful effects. There have been no asthmatic attacks.

CASE 3 A female of thirty years who had severe coryza and sneezing at the height of the ragweed season in 1935 used a two per cent solution of tannic acid as a spray several times. She found this concentration as well as the $\frac{1}{2}$ per cent solution irritating. There was no alleviation of symptoms.

CASE 4 K H, an adult female, a biologist at Cold Spring Harbor of twenty-seven years who had hay fever volunteered to use two per cent tannic acid as a spray during the height of the ragweed season. She found the solution irritating. She counted the number of sneezing episodes and the number of sneezes or episodes with and without therapy. Since these studies were not correlated with pollen counts they were not conclusive. Her opinion, however, concided with that of the writer—that this solution produced no improvement in her case.

CASE 5 O W, an unemployed Finnish doorman of forty-eight who had had diabetes for many years and who was receiving insulin for his glycosuria, showed skin reactions that were essentially negative to the routine set of inhalants. His reaction was one plus to 0.1 of ragweed. In spite of his practically negative skin reaction he was clinically extremely sensitive to pollen during the ragweed season. In addition he had marked hypersensitiveness to cold draughts at various times. Odors of paint, camphor, and other sharp substances led to sneezing and nasal discomfort. He began to receive ragweed and dust injections in May. At that time he also complained of itching eyes and a stuffed nose. The itching eyes and stuffed nose did not seem to be related to the pollen in season at the time. He was advised to use a one-half per cent solution of tannic acid as a spray and if necessary to use a small amount of one-quarter per cent tannic acid in his eyes. It was found that tannic acid used as indicated decreased his discomfort. He continued to use tannic acid up to November when nasal symptoms diminished. He went through the entire ragweed season without any marked symptoms of hay fever. In his case, contrary to the experiences which are given in the other cases, which did not find tannic acid useful, tannic acid was used throughout the ragweed season with no ill effects, and apparently was efficacious in preventing symptoms. In December the nose and throat consultant reported that there was bilateral maxillary sinusitis, that the septum was deviated to the right and that the tonsils were diseased. In this instance as far as the writer was able to observe, the tannic acid was especially useful in avoiding paroxysms of sneezing excited by draughts of cold air and large

quantities of dust occurring incidental to house cleaning

CASE 6 H K was a thirty-seven year old housekeeper who was constitutionally allergic and had rather severe hay fever in the fall. She was skin sensitive to a large variety of inhalants. It was very frequently necessary for her to go to the country and open up the country house during the winter. On these occasions there was a large amount of packing and dusting. House openings of this sort were followed by paroxysms of sneezing and a good deal of nasal discomfort. She was advised, as a preliminary to these changes of residence and to dusting and work of this sort, to spray her nose with one-half per cent tannic acid several days ahead of time and to continue spraying during the time that she engaged in her occupation. According to her report the use of the tannic acid spray diminished considerably the nasal discomfort attendant upon any type of dusting, or contact with malodorous materials.

The response of the normal mucous membrane to tannic acid varies. Some individuals who have sprayed their nose with one-half per cent solutions seem to find it not irritating at all. Others sneezed for several minutes and disliked the effect. The same is true of allergic patients with various types of nasal complaints. A patient may refuse to use the tannic acid because of sneezing and irritation, in these cases it is to be discontinued. On the other hand, there are some individuals who use it continuously and find it in no way objectionable. The following prescription may be written to make thirty cc of the solution

Tannic acid USP 0.15

Chloretone 0.15

Aqua qs ad 30.0

S To be used as a nasal spray from two to three times a day

It may be advisable in certain instances to use a higher concentration if the low concentration is well-borne but there is only slight clinical improvement. In that event a one per cent solution may be prescribed. The writer has used solutions, as will be noted from the case histories, as concentrated as two per cent. When used in attempts to prevent poliomylitis, even higher concentrations have been recommended. The patient should prefer-

ably use the solution with an all-glass nebulizer, and spray his nose from two to three times a day depending upon his reaction.

Discussion

If employed alone, tannic acid was apparently washed out by the enhanced secretions present during the ragweed season as fast as it was sprayed in. In the cases where it was employed pre-seasonally, injections of ragweed were also administered. There was no instance in which the tannic acid was used pre-seasonally for a suitable period with the ragweed injections omitted.

It is of interest to remark that tannic acid does not agglutinate ragweed pollen or coagulate pollen protein with the same facility that it causes precipitation of other proteins or cells.⁸ The further study of precipitation reactions of tannic acid and other astringents suitable for nasal instillation with the other allergenic inhalants would be of considerable interest and importance.

Tannic acid has the remarkable property of sensitizing the surfaces of bacteria and red cells for phagocytosis.⁹ It is, perhaps, by a mechanism related to this surface action or unicellular organisms that a protective process may have been set up in the nasal mucosa, in the instances where relief was afforded in the cases yielding to this form of therapy.

Summary

Tannic acid solution has been employed successfully in the form of a spray in certain types of allergic rhinitis. It is recommended as an inexpensive adjuvant to the usual procedures

AUTO TRANSFUSION IN ECTOPIC PREGNANCY

ARTHUR J WALLINGFORD, M D *Albany*

From the Gynecological Service of the Albany Hospital

Several papers have been written in recent years on the maternal morbidity and mortality in the United States. These articles have all stressed the importance and necessity of lowering the death rate in pregnant women, and very little has been said about the deaths caused by extrauterine pregnancies. Statistics show that maternal mortality due to ectopic gestation is surprisingly high. Gordon¹ in a recent paper summarized statistics as follows:

The New York Academy of Medicine report on New York City for 1930 to 1933 listed 120 deaths from ectopic gestation, 5.9 per cent of the total maternal mortality. The Philadelphia report considering 717 maternal deaths from 1931 to 1933 reported 33 ectopic deaths, 4.6 per cent of the total, or 11 per cent of the cases under twenty-eight weeks. The Children's Bureau "Study of Maternal Mortality in Fifteen States" for 1927 and 1928 in 13 states, and for 1928 only in 2 more states, attributed 314 deaths to ectopic gestation, or 4 per cent of the total 7,380, deaths from hemorrhage of placenta previa were but 347, and deaths from post-partum hemorrhage 374.

On the basis of 16,000 deaths annually assigned to pregnancy and childbirth, it is likely that about 1,000 women die from ectopic pregnancies every year. Tenney² in a review of 150 cases of tubal pregnancy treated on the Gynecological Service of the Boston City Hospital during the past eight years stated that there were three deaths. In Albany last year there were thirteen maternal deaths. Three of these deaths were caused by tubal gestation. Since death in most cases of ectopic pregnancy is due to shock, hemorrhage, or sepsis, blood transfusion is an excellent therapeutic measure.

In this paper, the writer presents a practical method for transfusion in which the blood present in the peritoneal cavity is recovered and returned to the circulation of the patient. This procedure, used successfully in twenty-six cases, has been prompted, *first*, by the observation of the

large amounts of blood present in the peritoneal cavity, and *second*, by the immediate need of blood in the systemic circulation of the patient either before or after operation.

The advantages of autotransfusion are, *first*, that there is no necessity for another donor, and *second*, that the blood is immediately available when it is urgently needed. Cottis,³ in his discussion of the value of auto blood transfusion, states:

'In the event of severe hemorrhage into the abdominal cavity, whether it is before or during operation it is not good surgery to throw away the blood. This method of returning it to the patient is simple, safe and effective. It is a conservative measure which is worthy of more general use.'

When autotransfusion is employed there is no danger of a foreign protein reaction which may occur sometimes even if the blood of the donor is theoretically compatible with that of the patient. Levine and Segall,⁴ in their studies of post-transfusion reactions, state: "A long operation in which ether is used alters the patient's serum as regards its haemagglutinin properties. This is not permanent but disappears in the first twenty-four hours after operation."

The terms autotransfusion, autohemofusion, and autotransfusion are used synonymously in the literature. Autotransfusion was employed successfully in 1914 by Johannes Thies⁵ of Leipzig. He reported three cases of ruptured ectopic pregnancy where he procured the blood free in the peritoneal cavity and returned it intravenously to the patient. Previous to this time, English investigators mentioned the advisability of autotransfusion and used it in several cases of leg amputations. Lichtenstein⁶ in 1918 reported its use in thirty-nine cases of extrauterine pregnancy. The first article on this subject to appear in this country was published by White⁷ in 1923. Autotransfusions in ruptured tubal pregnancies have been reported by Cottis,³ May,⁸ Maynard

*Read at the Annual Meeting of the Medical Society of the State of New York
Rochester, May 25, 1937*

and Rees,⁹ Appleby,¹⁰ Love,¹¹ Ricci and Di Palma,¹² and others. In 1923 Burch¹³ summarized 164 cases, all European, with only two deaths. Davis and Cushing described a method for autotransfusion using the blood lost during prolonged neurosurgical operations. Gray obtained the blood from a spleen after splenectomy and used it with good results. Coley reported a case of autotransfusion where the blood from a traumatic ruptured spleen was employed. Recently Watson and Watson reported the successful use of autotransfusion in the treatment of a patient who had a laceration of the heart.

Blood for autotransfusion has been obtained by various methods, treated in many different ways, and administered to the recipients by a variety of technics. In gynecology and general surgery, the blood escaping from tubal pregnancies or from ruptured viscera has been allowed to remain in the peritoneal cavity for absorption. At other times it has been removed from the peritoneal cavity by a suction apparatus or a syringe or has even been dipped up by cups or squeezed out of tampons and then returned to the patient's veins. In general medicine the blood has been treated by radium, x-ray, chemicals or kept in an incubator before being returned to the circulation. In obstetrics blood obtained from the placenta has been given per rectum. Farrar,¹⁴ in her article describes a technic similar to the one employed by the writer. She used this form of transfusion in patients where blood had escaped into the peritoneal cavity during hysterectomy and from tubal gestation.

Technic

In the cases herewith reported, blood was obtained from the peritoneal cavity before, during, and after the removal of the ectopic gestation and then immediately returned to the patient's circulation by intravenous transfusion. The apparatus used for recovering the blood from the peritoneal cavity is a suction outfit similar to the one ordinarily employed in recovering fluids in the course of abdominal operations. This consists of a source of suction, which in the operating rooms of the Albany Hospital, is the radiator, a part of the vacuum heating system. A

wash bottle with a two-holed rubber stopper is placed on the floor. Through one opening in the stopper a glass tube with a rubber delivery tube is attached to the source of suction. Through the other opening a tube is connected with a suction flask on the instrument table as shown in the diagram (Fig 1). The suction flask on the instrument table is plugged with a one-holed stopper. From a side limb in the flask a tube is attached to the source of suction. Through the hole in the rubber stopper a tube with sucking tube attached is extended to the peritoneal cavity. The suction flask and tubes are all sterilized before operation. Immediately before use, a nurse washes out the flask and tubing with normal saline and then places forty c c of

Fig 1

two per cent sodium citrate solution in the flask. In each case from 350 to 900 c c of blood were obtained from the peritoneal cavity.

The operator can proceed without difficulty while the suction is working. Now and then the instrument nurse rotates the flask containing the blood, citrate, and saline solutions. After all the blood or a sufficient amount is obtained, the instrument nurse filters the blood through at least twenty thicknesses of gauze and measures it. If more of the two per cent citrate is needed to make the citrate solution ten per cent of the total volume, the necessary amount is added. While the blood is being prepared an intern starts an intravenous injection of normal saline and is ready to give the citrated blood as soon as it is filtered. The blood is kept at body temperature by immersing the flask in warm water. In the cases reported the transfusion was completed

usually before the abdominal operation was finished

Although the cubital vein has ordinarily been used, any vein, even a large vein of the omentum, can be used if the brachial vessels are collapsed

Citrated blood has been used without danger. When one considers that if 1000 cc of citrated blood are given, the patient receives only two gm of sodium citrate, and since over twice this amount of sodium citrate may be given safely to the patient this method may be considered feasible

Contraindications

The contraindications to autotransfusion are three: infection, malignancy,

TABLE I—AUTOTRANSFUSIONS IN TWENTY-SIX PATIENTS

Age of Patient	Citrated Blood cc	Age of Patient	Citrated Blood cc
28	400	38	400
42	350	40	350

28	250	25	150
22	400	26	200

and old stagnant blood from long-standing tubal pregnancies. Old chronic salpingitis apparently does not contraindicate using the peritoneal blood associated with tubal pregnancy. A careful examination of the peritoneal cavity for evidence of infection should be made at the time of operation. If any such evidence is found the blood should not be used. It is also possible that bacteria may be introduced into the blood stream of the patient as a result of faulty technique

Case Reports

CASE 1 Mrs. R. F., aged twenty-eight, entered the Albany Hospital December 8, 1933, in a state of shock. She had been seen in her home one-half hour previously. At that time she was cold and clammy, her pulse was thready and weak, and she was very pale. A diagnosis of intra-abdominal hemorrhage, probably caused by a ruptured tubal pregnancy, was made. Her present illness started three days

previously with vague, low abdominal pain on both sides, but emphasized on the right. There was some nausea. She consulted her physician who felt that she had a pregnancy in a retroflexed uterus because she had missed two periods. There was no vaginal bleeding. The morning of admission the pain became more acute and she called her doctor. He made a pelvic examination and then advised the patient to assume the knee-chest position, in order to bring the fundus of the uterus forward. After a few minutes in this posture the patient almost went into shock. At this time I was called, and without any further attempt at examination, the woman was rushed to the hospital and operated upon. An attempt was made to obtain a donor for blood transfusion.

The operation was performed under ether anesthesia by the writer. A midline incision was made. Free blood appeared in the peritoneal cavity and the suction tube was placed there. Approximately 500 cc. of blood was obtained. A ruptured left tubal pregnancy was found. Under ether anesthesia, the left tube and ovary and appendix were removed by the author. Prior to and during the operation the radial pulse was not perceptible. As soon as the incision was made an intravenous saline injection was started. The citrated blood was also given and the patient left the operating room in good condition. Her pulse rate was 120. She made a normal convalescence and was discharged from the hospital in good condition.

In this case, autotransfusion may have been a life-saving measure because a suitable donor was not immediately available.

CASE 2 Mrs. M. I., aged forty-two, entered the Albany Hospital on April 20, 1934, complaining of abdominal pain and discomfort with periodic attacks of nausea and vomiting, of easy fatigability and shortness of breath.

The present illness started seven weeks before admission. The onset was sudden and acute, with marked pain, nausea, vomiting, and weakness. She did not faint. Her last menstrual period occurred three months previously. She did not consider herself pregnant because of the amenorrhea, for she had been irregular for the past two years. She had four children who were living and well. Following the onset of her present illness she had a small amount of vaginal spotting which had persisted until the present. For the seven weeks before admission, she had been confined to bed because the slightest exertion increased all of her symptoms.

Before admission to the Albany Hospital she had been under observation in another

hospital. There she was told that she had "fibroids." One morning while in the hospital she fainted after straining at stool in the lavatory.

On admission to the hospital, physical examination showed a well-developed, well-nourished female, rather pale and dyspneic. Mucous membranes were pale. Heart and lungs were normal. The abdomen was distended, very tender, and tympanitic on top. No definite masses were palpable. Pelvic examination showed a tender, boggy mass filling the culdesac. The body of the uterus was not definitely palpated. A preoperative diagnosis of hematocoele and ruptured tubal pregnancy was made.

Urine examined in the laboratory was normal. Friedman's modification of the Aschheim-Zondek reaction was positive for pregnancy. Examination of the blood showed the hemoglobin to be seventy per cent, white blood cell count was 13,350. The Wassermann test was negative.

Operation was performed by Dr. John A. Sampson on April 25, under ether anesthesia. On opening the peritoneal cavity a large amount of old blood was found. The pelvis was filled with a mass of the various viscera slightly adherent. As this mass was disturbed fresh bleeding occurred. The uterus was in normal position, slightly enlarged and soft. A large hematocoele filled the culdesac. On the right side a three to four months fetus was found. The placenta was attached to the right broad ligament, tube, and pelvic wall. An appendicectomy, panhysterectomy, and bilateral salpingo-oophorectomy were performed. The fetus and placenta were also removed. Drainage was established through the vagina and a stab wound. During the operation approximately 350 cc of blood were obtained from the peritoneal cavity, citrated, filtered, and given to the patient intravenously.

The convalescence was uneventful and the patient was discharged in good condition on May 13.

CASE 3 Mrs. L. A., aged thirty-two, entered the Albany Hospital on May 21, 1934. She had been seen one hour earlier in her home. At that time she complained of faintness, pain, nausea, and dyspnea. Her last regular period had occurred in March. In April, two weeks after normal time, she had slight pain low down in the right side. This was followed by a small amount of vaginal bleeding. The pain and the bleeding persisted until two days before admission. At no time did she take to bed. Two days before admission she fainted, because she "felt weak." That day she took a 200-mile automobile trip. The day before admission she had more pain than at any other time

previously. This pain, so severe that she had to go to bed, was more intense on the left side. The pain and weakness persisting till the next day, she called her family physician. When he saw her, she was cold and clammy, but did not faint. On questioning, she stated that today she had pain in her right shoulder and also pressure in the rectum as if the bowels wanted to move.

Physical examination revealed the usual findings of secondary anemia. The abdomen was moderately distended, tympanitic, and tender low on both sides. Pelvic examination showed a uterus of normal size and position. There was a tender mass on the left side, and a soft tender mass in the culdesac.

Laboratory examination of the blood on admission to the hospital showed Hemoglobin, fifty-five per cent, white blood cell count, 23,200, Wassermann, negative.

On the evening of the day of admission, an operation was performed by the writer. Under ether anesthesia a low midline incision was made. As soon as the peritoneal cavity was opened, a large amount of bloody fluid was encountered. A tubal pregnancy was found on the left, and the left tube and ovary were removed. Before the incision was closed 700 cc of blood, obtained from the peritoneal cavity, were returned to the patient's circulation.

After seventeen days in the hospital, she was discharged in good condition.

CASE 4 Mrs. C. H., aged thirty-four, entered the Albany Hospital on January 3, 1936, because of severe pain in her lower abdomen. This pain was worse on the right side and was associated with nausea. There was no vomiting. She stated that ever since her last menstrual period, which started December 1, she had not been feeling well. Her period, which started on time, lasted for fifteen days and vaginal spotting had continued. She had had eight previous pregnancies—six children living and two miscarriages. The last was in June 1935.

The severe pain actually started the morning of admission. She felt a little faint. Temperature was normal, pulse about 124. The abdomen was moderately distended and very tender low down on both sides, particularly on the right. A diagnosis of tubal pregnancy was made. A pelvic examination was not attempted because of the danger of causing more internal bleeding. She was operated upon the same day, under ether anesthesia by the writer. A low midline incision was made. The peritoneal cavity was filled with both fresh and old blood. This was aspirated, citrated, and filtered. Approximately 900 cc were returned to the patient intravenously while the abdominal

operation was in progress. Her appendix, right Fallopian tube, and ovary were removed. She made a normal convalescence and was discharged in good condition on January 23.

CASE 5 Mrs E M, aged thirty-six, was first seen on the morning of April 22, 1936, because she had severe abdominal pain and had fainted. When I saw her she was pale and gasping for breath. If she attempted to sit up, she would faint. Her abdomen was distended and very tender. Pelvic examination was not made. She said that when she went to bed the previous evening she felt perfectly well but during the night she was seized with severe pain, particularly in the lower left quadrant, which continued and increased, spreading over her entire abdomen. She vomited several times. She also complained of pressure sensations on the rectum as if her bowels wanted to move. She experienced some pain in her right shoulder.

She was brought to the hospital and operated upon immediately by the writer. A low midline incision was made under ether anesthesia. A large amount of fresh blood was found in the peritoneal cavity. A suction tip was inserted at once and the fluid blood aspirated. The left Fallopian

tube was removed because it was ruptured in its middle third. During the operation approximately 900 cc of citrated blood were obtained, and, properly filtered and warmed, returned to the patient's circulation. She left the operating room in good condition. Her convalescence was uneventful and she was discharged from the hospital May 10.

Summary

1 Autotransfusion is a standard procedure in the Gynecological Service of the Albany Hospital.

2 In many cases of ectopic gestation, blood may be obtained from the peritoneal cavity during the operation and returned to the patient intravenously as soon as it has been properly citrated and filtered.

3 A simple technic for this purpose is described.

4 Auto blood transfusion has been successfully employed by the writer in twenty-six patients with ectopic pregnancies, all of which recovered.

EXHIBIT SHOWS HOW LIFE TICKS

Displays that they may operate themselves by means of push buttons enable visitors to the "Story of Man" exhibition at the New York Museum of Science and Industry in Rockefeller Center to watch the rhythm of their heart-beat, measure the speed at which their muscles tire, determine the keenness of their sense of smell, and do many other things that will give them a clearer idea of how the mechanism of human life actually ticks.

The exhibition opened at the Museum on November 6 and will continue for several months. The material was constructed abroad for the Museum and is being shown for the first time in America. It includes, in addition to numerous operating exhibits, actual specimens of organs and bony structures in the human body prepared by the famous Spalteholz process, together with

demonstrations of body functions and processes dramatized in models, pictorial devices, and many other media.

In presenting this visual "Story of Man," the tale of the development of the human being begins with a group of models showing, first, the fertilization of the human ovum, enlarged 200 times, and continuing through the various phases of cell growth up to the stage where the embryo itself begins to take on form. From this point, the story is taken up in a series of actual human embryos, all Spalteholz specimens so prepared that they are transparent and show plainly the tiny bones and organs in process of formation, following the embryo from month to month up to the time of birth. A group of Spalteholz specimens of animal embryos provide interesting contrasts and comparisons.

CLINICAL EVALUATION OF TERTIARY BUTANOL HYDROGEN PEROXIDE AS A FUNGICIDE

FRANK C COMBES, M D, *New York City*

The treatment of dermatomycosis is essentially local. Notwithstanding several reports extolling the therapeutic efficacy of parenteral injections of fungus extracts, their use in desensitization of the individual has not met with sufficient success to warrant their continued use. Furthermore, I doubt whether their rationale in treatment is theoretically sound. They may be instrumental in attenuating the normal fungistatic elements of the skin, thus defeating the very purpose for which they are administered.

Of all the fungicides at our disposal, greater dependence can be placed on the simpler chemical substances, such as iodine, sulphur, chrysarobin, salicylic acid, potassium permanganate, and hydrogen peroxide. Of these, iodine in proper dilution has been the most reliable for general use.

An aqueous solution of hydrogen peroxide, if not for its unstable nature, should be an excellent application in mycotic infections. It undergoes a slow process of reduction with liberation of a portion of its oxygen content. This nascent oxygen has a powerful oxidizing effect and is destructive to organic matter. Fungi are facultative anaerobes and subsist on epidermic tissue. The destruction and removal of this tissue definitely inhibits their proliferation. In addition, hydrogen peroxide is directly a fungicidal agent. According to Gifford,¹ its germicidal action does not depend upon the liberated oxygen, but upon the hydrogen peroxide molecule. Certain organic substances, especially blood and pus, exercise a powerful catalyzing action on aqueous solutions, so that the oxygen is given off rapidly. A stabilized solution would liberate oxygen more slowly and we could take advantage of the effect of this nascent oxygen and simultaneously the fungicidal properties of the peroxide molecule. We have such a solution in a

preparation of tertiary butanol hydrogen peroxide.

Pure hydrogen peroxide is an unstable crystalline substance, and in the past has found its greatest use in the official *Liquor Hydrogenii dioxydi*, which represents a three per cent solution by weight H_2O_2 . At ordinary temperatures it is unstable and when dispensed is often of little practical value. Hydrogen peroxide possesses many of the same properties as water, one of which is its solubility in various solvents. A substance which dissolves water will dissolve hydrogen peroxide. For example, tertiary butanol will dissolve water or hydrogen peroxide in all proportions, whereas mineral oil fails to dissolve either to any appreciable extent.

Consequently the ideal organic solvent for hydrogen peroxide would be one difficult to oxidize and in which the peroxide is soluble in all proportions. A further requisite is that the resulting solutions be stable and capable of slow liberation of oxygen on contact with dead organic matter. Several different alcohols, both aromatic and aliphatic, have been tried with varying success. The actual number of alcohols available is somewhat limited, some being too expensive to be practical. The higher alcohols are either solid or fail to dissolve any appreciable amount of hydrogen peroxide. Other alcohols will dissolve plenty of peroxide but are themselves easily oxidized and give unstable solutions.

Table I shows the various solvents employed with qualitative results on the solvent power for water and hydrogen peroxide, the resistance of solvent to oxidation, and the stability of the peroxide solution. The grades, "excellent, good, fair, poor and very poor," are designated by "E", "G", "F", "P", and "VP". "-" signifies that a given characteristic is unknown.

From the Department of Dermatology, New York University College of Medicine and the Dermatological Service of the Third (New York University) Medical Division, Bellevue Hospital. Service of Drs. Howard Fox and Edward R. Maloney.

It will be seen from Table I that tertiary butanol is the best solvent from both a theoretical as well as from an experimental viewpoint since it dissolves water

and hydrogen peroxide in all proportions, is difficult to oxidize, and gives a stable solution

The preparation of the peroxide solution in tertiary butyl alcohol is outlined by Milas and Sussman²

To 100 cc of 30 per cent hydrogen peroxide was added 400 cc of pure tertiary butyl alcohol and the solution treated with small portions of anhydrous sodium sulfate whereby two layers separated out. The alcohol layer, which contained most of the hydrogen peroxide, was removed and dried with anhydrous sodium sulfate (Drierite). A solution of 6.32 per cent hydrogen peroxide in tertiary butyl alcohol was obtained, giving a recovery of 93.8 per cent. This solution can be easily concentrated by vacuum distillation of the alcohol at room temperature to any desired concentration without any loss of the peroxide, provided an all-glass apparatus is employed. When hydrogen peroxide solutions of this sort were allowed to stand at room temperature for over six months, only a small decrease in hydrogen peroxide concentration was noted.

The properties of tertiary butanol hydrogen peroxide are as follows: *Assay*—About seven per cent H_2O_2 , although it can be made in any strength. *Practically* all of the other ninety-three per cent is tertiary butanol. *Inert substances present*—Water and a trace of sodium sulphate. The amount of water is quite low but there is no method available to determine it. *N. V. M.* about 0.05 per cent. *Surface tension*—Twenty-five dynes per cm (Water 71 dynes per cm) at 25° C. *Reaction*—Acid (methyl red). *Specific gravity*—0.850–0.859. *Preservative*—A trace of metaphosphoric acid.

The type of container used for the peroxide solution is important. A glass bottle of low free-alkali content is necessary. This bottle should be cleansed thoroughly with sulfuric and nitric acids before use to remove the free-alkali left after manufacture. Ordinary and ultraviolet lights appear to have no effect so that a white glass bottle may be used. This is not true of the ordinary aqueous solutions which deteriorate rapidly on exposure to air and light. The type of cap liner is important since many of these are destroyed by the peroxide. Tinfoil, Vinylite or cork liners are best. Bakelite or metal caps are also satisfactory.

The peroxide is fairly stable from 0-50 but over 60° C there is some decomposition. It may be said that the product is stable over all ordinary temperature ranges. It may be diluted with water or alcohol in all proportions although such solutions, especially the alcoholic, are not very stable. The amount of water which the product may pick up from the air is not deleterious.

Assay of Its Antiseptic Value

Phenol coefficients and cup plate tests have been done by the Food and Drug Administration methods.³ These results have been compared with the findings of McCulloch on other antiseptics. It must be remembered, however, that the results of different workers vary considerably. In addition, the activity of an antiseptic on a culture plate is not necessarily an index of its activity when in contact with organisms in animal tissue. The fungus used in this test was the *M. albicans*. Comparative tests were also performed with *E. typhi*, *E. coli*, and *staphylococcus aureus*. Table II compares the phenol coefficient of tertiary butanol peroxide with other antiseptics. The latter determinations are from McCulloch.⁴

Unless otherwise noted, the coefficient applies to the pure or original substance. The tertiary butanol peroxide contains seven per cent hydrogen peroxide. Mercurochrome figures are for the solid, not for the usual two per cent aqueous solution. The coefficient of this would be two per cent of the value given. Figures for Zonite, Listerine, and Pepsodent are for the commercial antiseptics as sold.

During the clinical use of tertiary butanol peroxide, it was suggested that much of the benefit derived might be due to the vehicle instead of its peroxide content. This is not so, since tertiary butanol appears to have little germicidal activity, which was proven clinically. In general, it may be said that the greater the number of carbon atoms in the alcohol the greater is its germicidal efficiency. However, if the chain of carbon atoms are broken up as in secondary and tertiary alcohols, the toxicity for pathogenic organisms is decreased. The figures in Table III, taken from McCulloch⁴ illustrate this.

Therapeutic Results

The therapeutic activity of tertiary butanol peroxide has been observed for a period of six months, during which time it has been used in cases of dermatomycosis. I am able to report thirty-two cases. It is extremely difficult to keep patients with fungus infections of the feet under observation as they fail to return when they gain relief. At least an equal number failed to return or continue under observation for sufficient time to include them in this report. A large majority of these showed marked improvement and many of them were probably cured. The cases reported are those which were observed over a sufficient period to assure that they were probably rid of the infection. In some cases infection of the nails will in the future, result in a reinfection of the epidermis. A one per cent solution was used and found

TABLE III

Alcohol	Phenol coefficient for <i>E. Typhi</i>
Methyl	0.026
Ethyl	0.040
Butyl	0.237
Hexyl	0.45
Sec butyl	0.152
Ter butyl	0.081
Ter amyl	0.082

most satisfactory. The greater concentrations were found too painful on the broken skin to be practical. Table IV designates briefly the type of cases treated and summarizes the results. Nineteen patients (sixty per cent) were clinically cured, nine (twenty-eight per cent) showed definite improvement. Only four patients failed to improve or became worse under treatment.

Experience has shown that the preparation cannot be used on very acute cases where moist dressings are indicated. Its use following the subsidence of the acute reaction has been quite effective in practically all patients. The cases showing the most remarkable results have been those with maceration, vesiculation without edema, and those with desquamation of the soles following the rupture of "dry vesicles." It is also effective in relieving temporarily, associated hyperhidrosis. Incorporation of the preparation in an ointment has not been satis-

factory This was probably due to the instability of the peroxide in this type of base

All the patients applied the solution two or three times daily with a cotton swab or camel's hair brush They were told to avoid the use of soap except those with tinea capitis In these cases daily shampoos were prescribed Constant exposure of the hands to the one per cent solution does not appear to be damaging However, the six per cent solution is quite painful, even on the unbroken skin

Conclusions

- 1 Tertiary butanol is an ideal vehicle

for hydrogen peroxide It is not readily oxidized and forms a solution in all proportions which are stable under all ordinary conditions

2 Perhexogen (tertiary butanol peroxide) is an effective fungicide, easily applied, rapid in action, stainless, and practically odorless

TREATMENT OF THE INDUSTRIAL BURN

JOHN J WITTMER, M D, Brooklyn

In the treatment of burns, regardless of the causative agent or degree, a treatment should be selected calculated to give the shortest period of disability with a minimum of pain and permanent deformity. In any but superficial burns, success can be achieved only from the intelligent and persistent execution of an adequate program. In the main, superficial and minor burns may be treated by the general practitioner, but the treatment of deeper and more extensive burns is a definite surgical procedure.

Long before our present day conception of asepsis, the toxemias and the treatment of shock were recognized, but the vast majority of all severely burned patients and those with even superficial burns covering a large area, generally died.

Time does not permit a resume of all the earlier methods of treatment or the discussion of the various types of experimental work which was carried out and which brought the attention of the medical profession to the cause of death. This experimental work has resulted in a more rational treatment and greater saving of life.

The cause of burns may be divided into five classes

- 1 Moist or dry heat
- 2 Fire.
- 3 Chemicals
- 4 Actinic radiant energy
- 5 Electricity

Burns from any of these causes produce lesions which are essentially similar.

In classifying burns as superficial, we include all those in which the skin epithelium is not completely destroyed.

Systemic reaction, Toxemia Aside from the initial shock caused by excessive burns the real problem concerns the systemic reactions of a toxic nature which may be of sufficient severity to jeopardize the patient's life. It is stated that the severity as concerns life, depends not so much upon the depth of the trauma or the gross amount of tissue actually destroyed, as on the extent and location of the skin

area involved. Living skin, when subjected to burning, is capable of developing certain chemical by-products the exact nature of which is unknown and which when absorbed into the circulation produce definite systemic reactions. In this report, skin differs from other tissues, such as that of fat or muscle, wherein burning is accompanied either by a very minor degree of such a reaction or none at all.

Aldrich¹ believes that the toxemia of burns is the result of massive infection of the burned area with hemolytic streptococci. This may be an added factor in some instances but bacterial infection as the sole cause of toxemia is not borne out by other writers.

The burning of certain particular skin areas seems to be accompanied by the development of more severe grades of toxemia than other areas of similar extent. This is particularly true of the so-called "blush area," which comprises the face, neck, and upper torso especially the anterior part of the chest wall. The rich blood supply of this area and particularly its sensitive vasodilatory capillary system doubtless partly at least accounts for the rapidity and degree of toxic absorption.

There is apparently a definite latent period of about eight hours between the occurrence of a burn and the beginning of toxic absorption since it has been shown experimentally that if complete excision of a burned skin area be performed within such a period the toxic constitutional reaction does not develop whereas if excision be delayed beyond this latent period the procedure of excision is without avail. The eight hour latent period of toxic absorption as just described, represents not the interval beyond the limits of which clinical symptoms of toxemia may be expected to appear, but only the period beyond which the surgical eradication of the local lesion can no longer be depended upon to prevent the subsequent development of toxemia. The clinical symptoms of toxemia do not ordinarily appear for

*Read at the Annual Meeting of the Medical Society of the State of New York
Rochester May 25 1937*

from twenty-four to forty-eight hours, or even longer, after the infliction of a burn. That the development of burn toxemia depends upon absorption of toxin by way of the blood stream is apparently demonstrated by the fact that toxemia does not take place if the vascular drainage from the burned area be interrupted by ligation of afferent blood vessels.

Last year Wilson, Rowley, and Gray reported the successful use of Eucortone, an extract of suprarenal cortex, used as an adjuvant measure in the treatment of three cases of definitely established severe acute toxemias following burns, with recovery in each instance. They intend to carry on further investigation of the action of this extract.

Blood concentration This concentration is directly the result of loss of fluids by way of the burned area, and it varies with the severity and the extent of the burn.

Underhill³ has reported clinical increases of hemoglobin up to 145 per cent. This blood concentration may in itself cause death because the viscosity may lead to impairment of capillary circulation diminishing of oxygen-carrying capacity of the blood lowering of temperature, suppression of urinary secretion and suspension of the vital activities.

Locke⁴ analyzed the erythrocyte count in nine cases of severe burn and found that in five cases in which the count exceeded 9 000,000 to the count, all the patients died whereas the other four persons wherein the count was less than 7 260,000, recovered.

Pack⁵ believes that the maintenance of a forty percent increase in the hemoglobin is inconsistent with life.

Chloride retention The researches of Underhill,³ later established by other investigators, show the chloride content of the blood in burns is characteristically considerably reduced, in severe cases reaching fifty percent. This reduction of the blood chlorides is not accompanied by a corresponding urinary chloride excretion, in fact, the very opposite effect occurs, the urine showing a markedly decreased chloride output. Therefore the maintenance of the proper proportion of blood chlorides seems to be another field for investigation in the treatment of burns.

Burn toxemia The clinical manifestations of toxic absorption usually appear only after twenty-four to forty-eight hours and consist of (1) elevation of temperature, (2) rapid pulse, (3) vomiting, and (4) drowsiness or delirium. The development of such symptoms may be expected to occur in all cases of extensive burns even though very superficial.

Pack⁵ considers as serious all burns deeper than first degree which involve one-tenth or more of the body surface. Burns deeper than first degree, which involve more than one-third of the body surface, may result fatally, and those involving more than two-thirds usually do result fatally in adults. Much less extensive burns in children terminate life.

The estimation of the severity of burns in accordance with their extent, relative to the total body surface is, of course, a rather inaccurate method, but it suffices in ordinary clinical cases.

Berkow⁶ has estimated the distribution of the body surface as follows:

Lower extremities (including the buttocks)	38%
Trunk (including neck)	38%
Upper extremities	18%
Head	6%
	<hr/> 100%

The hand accounts for one-fourth of the surface of the upper extremity. The foot accounts for one-sixth the leg one-third, and the thigh one-half of the surface of the lower extremity.

Treatment

The treatment of burns can be conveniently divided into two parts, treatment of the local lesion and treatment of the prevention of systemic reaction.

Shock

In the early stages of burns, i.e., before the end of eight hours, before toxic absorption has yet occurred there is real danger that the general condition of the patient will quite escape the attention of the medical attendant in his zeal to do something locally, particularly so, if he possesses the information that the local wound is the source of toxemia and is attracted to this area by the silent or expressed entreaties of both the patient and

TREATMENT OF INDUSTRIAL BURN

November 15, 1937

his friends. No undue anxiety need be felt, however, in the usual case of thermal burns, to hasten in the matter of local treatment, since a number of hours of grace are allowed by nature before the beginning of the onset of the other main factor in mortality—toxemia.

Treatment directed toward the relief of local conditions is contraindicated in the presence of shock. The truth of this is too rarely appreciated, and it is a common sight in some hospitals to observe the medical attendant laboring with the removal of clothing, cutting away blebs, and washing away contaminating debris, while the patient's systolic blood pressure is less than seventy, sixty, or even fifty mm of mercury, and the exposure incident to the manipulation is constantly adding in the further dissipation of heat from a body which already manifests a subnormal temperature. Therefore, the shock of hasty and unwise local treatment added to the shock already present as the result of the original burn, will undoubtedly precipitate a needless death.

The treatment of burn shock differs in no essential particulars from the treatment of shock otherwise induced. The essential features are the administration of large doses of morphine, the maintenance of body warmth by the application of external heat in a light tent or by hot water bottles and internal heat in the form of warm drinks or intravenous infusion, the lowering of the head to combat cerebral anemia, and the promotion of quiet and rest under the watchful eye of a competent attendant. During this period, local treatment may be completely disregarded except for the prevention, as far as is feasible, of adventitious local contamination. For this purpose the wounds may be simply covered with a sterile sheet or towels. It is again emphasized that toxic absorption does not occur for several hours, a period of time ample both for the treatment of the shock and for the institution of suitable additional treatment after the period of shock has passed.

Two important exceptions must be mentioned

1 In these cases in which the patient's clothing has caught fire the utmost care must be exercised immediately after the patient is seen to make sure that no smoldering material has been overlooked in the excitement

of transporting the patient to the medical adviser.

2 In attending cases of chemical burns one peculiarity of the traumatizing agent must be remembered, a prolongation of action is maintained until neutralization of the active agent is accomplished, either by natural or artificial means. Patients burned by chemicals should be quickly treated locally to assure complete neutralization of the chemical reagent before anything else is done. The neutralizing property of alcohol in connection with phenol burns can be involved immediately. In most other cases copious gentle washings with water is indicated, after which, application of an agent may be employed, weak acids for strong bases and vice versa.

In addition to the shock caused by an extensive burn, a condition of anhydramia also results. If a burn involves one-sixth of the surface area of the skin the loss of fluid in twenty-four hours may equal seventy per cent of the total blood volume. Rubner has shown that in starvation, an animal can live after loss of nearly all its glycogen and fat, one-half of its protein, and nearly one-half of its body weight, but that it dies from loss of one-fifth of its water. The fatal influence, therefore, of the great loss of fluids in burns is apparent. With such depletion the blood becomes concentrated, the circulation slowed, and the blood loses oxygen. Partial asphyxiation results, metabolic processes become altered, the heat regulating mechanism becomes impaired, the temperature falls and vital activities are suspended.

Here again the fact must be emphasized that the burn itself is relatively unimportant at first. Therefore attention to the systemic effects of the injury should embrace, besides the usual measures against pain and fall in temperature immediate intravenous administration of 1000 cc of normal saline solution at a rate not greater than 25 cc a minute, and thereafter fluid, particularly normal saline solution, should be introduced by every available channel in the amount of from four to eight liters in each twenty-four hours, until the capillaries have lost their abnormal permeability, fluids are retained, and the concentration of hemoglobin and of chlorides in the blood approach normal. Usually the critical period has passed in from twenty-four to forty-eight hours.

Local Therapy

1 Debridement Granted that chemical agents have been successfully neutralized and shock is absent or has been successfully combated, the attention is now focused on the local lesion. The first act is complete debridement in an effort to convert a contaminated wound into a clean one. If the contamination is superficial and does not involve a large area, the application of a paste of sodium bicarbonate made with warm water will frequently cleanse the area in addition to relieving the pain. This treatment is always applicable to a first degree burn where debridement is not necessary.

The contamination may be such, however, as to make necessary administration of a general anesthetic, following which the burned area is either thoroughly scrubbed with a sterile scrubbing brush and sterile water or saline solution until the area is completely clean, or resort is made to instrumental removal of contaminated tissue. This form of treatment is generally applied where there is charring of the tissue or in other deep burns of limited extent.

Blebs are punctured and cut away with scissors and the entire area finally thoroughly cleansed with some nonirritating fluid like normal saline solution. After the area has been thoroughly debrided and all vesicles removed as described, we prepare for the next step.

Fixation Method with Tannic Acid

The use of tannic acid was introduced by Davidson in 1925. The latest modification of Davidson's treatment is to spray the denuded area with a freshly prepared solution of five per cent tannic acid, until a coagulum of fair thickness has been established. Loose dressings are then applied and kept saturated with the tannic acid solution for twenty-four hours, or until the burned area is tanned a mahogany brown. When the burned area is sufficiently tanned all dressings are removed and the patient is placed in a tent to avoid pressure of the bed clothes.

In cold weather the inside of the tent is warmed by means of electric lamps and maintained at a temperature between 95 and 100 degrees F. Sterile pads or

sheets are always kept beneath the burned areas that rest on the bed.

Infection can and often does occur beneath the tanned area, but careful cleansing of the burned area prior to the application of the tannic acid will tend to reduce the incidence of infection. If pus forms, an incision is made in the crust and drainage established.

There are now available on the market various proprietary preparations containing tannic acid jelly plus a germicide. These preparations are stable and well-adapted for use on patients who have a small burned area and who do not require hospitalization.

If the burn is superficial, epithelization will proceed under the dried coagulum, but if the burn is deeper the tannic acid crust that separated between the fourteenth and twentieth day will leave a clean granulating surface, upon which skin grafting may be done.

Davidson bases his treatment on the theory that the toxin present in the red cells was due to the absorption of the products of protein autolysis at the site of the burn. In order to limit this absorption he produces a coagulum of the devitalized tissue only by the application of tannic acid. The dry crust thus produced presents loss of tissue fluids which leads to a lowering of the sodium chloride of the blood.

In addition, the tannic acid applications produce a definite analgesia and does not affect the normal skin. The advent of sepsis is usually prevented by the dry coagulum which forms an unfavorable medium for bacterial growth.

Up to this time we have dealt only with the tannic acid treatment of second and third degree burns.

You will recall that it takes many hours before the coagulum becomes dried and brown, during the interval the patient must be watched closely from rubbing the burned surface against the tent and removing the coagulum. Bettman⁷ overcomes the delay in the tannic process by fixing the coagulum and then immediately spraying with ten per cent solution of silver nitrate. This process shortens the time of hardening of the coagulum to two or three hours. Without the silver nitrate the hardening time is between twenty-four and twenty-six hours. The addition of

the silver nitrate adds an antiseptic action in the presence of a moderate degree of infection

Some authors have employed a two per cent solution of gentian violet, spraying it on in the same manner in which the tannic acid is applied. This solution also forms a membrane over the burned surfaces, much like tannic acid, and it is claimed that the incidence of infection is lowered due to the antiseptic action of the gentian violet. Other writers have employed a mixture of tannic acid and gentian violet.

Ointments containing any form of medication are contraindicated in the treatment of large second or third degree burned surfaces. They tend to cause maceration about the skin margins and prevent the formation of epithelium. When the wound has become cleansed it is far better to leave it exposed to the air without covering, applying a liberal coating of stearate of zinc, which, being a mild astringent, has the property of drying any of the areas where epithelization has begun.

Skin Grafts

When the burned areas involve the region of the joints it is well to apply traction during the process of healing. More important, however, is skin grafting in the regions of the joints, employing either Thiersch, Reverdin or pinch grafts.

To those of you who have employed tannic acid, you know that when nearly two weeks have elapsed, tannic acid crusts loosen and fall off or may be removed entirely. Healing has taken place but an area of granulation may be present. The granulated area is then prepared for the reception of skin grafts. It is frequently found difficult to entirely rid the area from pyocyanous and staphylococci despite frequent dressings with Dakin's solution or other antiseptics. In preparing these surfaces for grafts, therefore, the granulation should be entirely removed by means of a curette. Small areas of two or three inches should be curetted at one time immediately followed by the firm application of hot compresses to allay bleeding while curettage is being carried on in another section of the same granulating area. When large areas are in-

volved, a general anesthetic may be necessary. In smaller areas, circular nerve block with one-half per cent novocain is sufficient. After all granulations have been removed, compresses saturated with Dakin's solution should be applied every three or four hours and kept wet with the solution care being taken to protect the surrounding skin from irritation by the Dakin's solution. At the end of three or four days, examination of the burned area will reveal a bright red, healthy-looking and pus-free area which is now ready to receive skin grafts. The type of skin graft employed will, of course, depend on donor area available.

Treatment of Electric Burns

Electric burns differ from all other types of burns. The degree of heat is far more intense and the general aspect is radically different from the pathological picture of any other type. The intense heat observed in the electric contact burns, is not found in the so-called flash burns.

A flash burn is produced when an electric arc is formed close to the body but the current does not go through the part. The severity of the burn depends upon the proximity of the tissues to the arc and the length of time that the arc is maintained. These superficial burns do not differ in any material way from the ordinary burn or scald.

By contrast, in the case of an electric contact burn, the surface of the body forms one of the poles of the electric arc. The electric current passes through the body and the degree of heat attained at the point of the surface of the body when the contact is made is the temperature of an electric arc. If a burn is produced, no matter how small, an electric arc must have been formed. If the contact is so perfect that sufficient resistance is not introduced to develop an electric arc, the body simply sustains an electric shock which might produce anything from a slight tingle to instant death.

The temperature of an electric arc varies from 5500 to 7000 degrees, whereas the temperature of the acetylene torch is 4500 degrees.

This intense heat presents a characteristic picture

Local Therapy

1 Debridement Granted that chemical agents have been successfully neutralized and shock is absent or has been successfully combated the attention is now focused on the local lesion. Discussion

DR DAN MELLEN, *Rome*—Dr Wittmer has given us a splendid paper. He emphasizes that treatment for extensive burns is a definite surgical procedure, and he has clearly separated the causes of burns into five classes. Here very important information is given when he speaks of the latent period of eight hours between the beginning of a burn and the beginning of toxic absorption. He states that burn shock is essentially no different from shock of any other cause and that too often this condition is overlooked when that is the time to fortify against it.

His report on the blood study is interesting. Loss of body fluid is another point of

which Dr Wittmer has spoken emphatically and here he suggests that we correct this depletion of fluid in every manner possible. He warns us to make all wounds as surgically clean as possible. There is no doubt of our interest and we are grateful for his complete description of his tannic acid treatment. Another important message he gives us is that salves used in the treatment of a large area are of very little value. Anyone who has cared for an electric burn will agree with Dr Wittmer that they are certainly more difficult to treat than other burns. Relative to this he suggests that burned areas be resected before the state of serum formation begins.

THE CHARGE OF THE WHITE BRIGADE

Fear not the young nurse who stands by
the side

Of your man, when he's sick and in
pain,

For after a siege with his grunts and his
groans

She'll give him up gladly again

She may woo him to sleep with her voice
as she lays

Her cool hands on his poor fevered
brow,

But remember, you wives, that this menace
in white

Sees him not with the eyes of his frau

To her, he's a bulk to be freed of its pain

Just a means of her own daily bread

He gets egg on his sheet, and toast in
his hair

And his feet dangle out of his bed

He snores all night long with his mouth
open wide

While his teeth float around in a glass

No sex appeal lurks in that bewhiskered
chin

And his chorus is minus all class!

So lay yourselves down all you green-eyed
young wives

On your bed, and well know while you
rest

That this treasure of yours is as safe with
his nurse

As a bird on a bough in its nest

He may answer the maidenly prayer of the
one

Who got him for better or worse

But whatever his assets or charms to his
wife,

He's a pain in the neck to his nurse!

REFUGEES FIND REFUGE

Four German physicians, exiles from their native country, who had applied in Supreme Court for a mandamus compelling the State Board of Regents to license them to practice here, were notified on Oct. 20 that their licenses had been granted. The suits had been sought on the ground that the State Board had refused to recognize that any foreign physician with credentials showing that he had practiced for at least five years, was entitled to a license.

The physicians all of New York City are Dr Jeanette Sakheim, of 1776 Clay Avenue, Dr Benno Leigner, of 604 West 112 Street, Dr Max Loeb of 390 West End Avenue and Dr Norbert Lewin of 312 West Ninety-second Street.

"No children!" exclaimed a friend to a young matron who had been married several years. "And your husband wants an heir so badly."

"Yes I know," replied the woman sadly. "He's heir minded but not heir conditioned."

—*Medical World*

Professor Kranz: "What did you find out about the salivary glands?"

Stude: "I couldn't find out a thing. Professor, they're too darn secretive—*Purple Parrot*"

What the individual doctor is—that makes the Society—Dave Sugar in the *Detroit Medical News*

Examination of a victim of an electric contact burn may simply present a single small innocent appearing blister, but if the superficial blister is carefully cut away there is noted a central area of white necrosis surrounded by a narrow ring of hyperemia and edema. The size of the central area of necrosis is naturally dependent upon the size of the contacting electrode. The area involved is usually pyramidal with the top of the pyramid at the surface of the skin.

As a rule, in from thirty-six to forty-eight hours an electric burn loses its dry, crisp, circumscribed appearance, and becomes a serum saturated area with disintegrating walls and floor, progressing to profuse purulent secretion, large sloughs bathed in pus, exuberant granulations uncontrollable to the most radical antiseptics.

This disorganization may include muscle, tendon, joint capsule, even bone itself.

After a varying period of the treatment aforementioned, apparently unduly tedious and prolonged, firm granulation ultimately ensues and the final result will be the same as that ordinarily secured in other comparable burns. The period of disability will be greatly shortened and the certain extensive scar formation will be decreased by the application of the surgical principle of complete resection of the burn area before the stage of serum formation begins.

The application of this principle of complete resection and immediate closure by suture or skin graft to third degree electrical burns, produces surprisingly and uniformly satisfactory results.

The method has its limitations, the line of demonstration may not be sufficiently clear in tendons, cartilage or bone to warrant immediate resection of the eschar. Essential structures, such as large vessels, nerves, and joints, should certainly be spared if there is any doubt in the operator's mind as to their possible visibility.

Welles states that experience has taught

that the great majority of electric burn cases are far more successfully handled by complete resection and immediate closure by suturing and skin grafts, than by any other method.

First Aid Treatment

The first aider should be taught only the elemental procedures in the treatment of burns and particularly "that the less that is done, the better." Certainly the measures should be those of an obviously preliminary character that later can be maintained and continued by the doctor. They should be confined to (1) Putting out the fire or neutralizing the chemical, (2) Give fluids by mouth if patient is able to swallow, (3) Saturate parts with solution of bicarbonate of soda or fresh solution of tannic acid, (4) Cover parts with sterile dressings (loosely).

Summary

1 Shock must be considered as of primary importance and treatment instituted immediately.

2 Fluids are vitally necessary.

3 Debridement at an early stage may be the determining factor between life and death.

4 Tanning of the burned area prevents loss of tissue fluids, retards pus formation, and stimulates granulation.

5 Skin grafts should be used judiciously and particularly over joints to prevent deformities.

6 Electric contact burns command more respect than other burns. One must not be misled by the appearance of the area when it is first seen.

7 Ointments of any kind are definitely contraindicated in second and third degree burns.

8 First aid by the layman should be kept to a minimum and he should be allowed to do only the first rudiments of the treatment outlined above.

Preventive Medicine

"Should He Have Died of Heart Disease?"

Preventive Medicine and Cardiovascular Disease

CHARLES H. GOODRICH, M.D., Brooklyn
Presidential Address

As we begin the consideration of this fascinating subject it is desirable to reach a mutual agreement as to terms. In the old days several kinds of heart-disease were emphasized but not myocarditis which now is very stylish with fantastic decorations. In the same old days these were isolated well-separated, clinical entities. Now we find that the very prevalent myocarditis is interwoven with nerve-impulses, arterial changes, hyper- and hypotension with resultant degenerative changes in viscera or extremities. Thus we understand cardiovascular disease to be a combination of an overacting heart with tense spastic arteries, or an anemic frail heart with relaxed or spastic arteries, in either case a fibrosis so distributed in the circulation tubes that *maximum effect* upon function and structure alike *may be at any point* in the circulatory apparatus. Thus may be ultimately associated chronic hepatitis, splenitis, chronic nephritis, arteriosclerosis, especially important in the arteries of heart and brain, chronic myocarditis with fibrosis and enlargement, aortitis, and other things. All may be present if the disease is far advanced. "Except in the brain, and perhaps the kidneys, changes in the arteries nowhere else in the body exercise so profound an effect upon the organ to which they distribute blood as in the heart" (Alfred Cohn). This is our conception of the newer clinical entity which replaces or combines a number of old enemies proven to be interdependent and originating similarly.

What are these similar origins? They are legion. Quoting Turner "Everything has a cause and the cause of anything is everything." This expresses in a few words the idea that almost every occurrence of importance has causes innumerable tangled in unbelievable complexities. A factor in most cases of cardiovascular disease is hypertension. What comes first? Sometimes we think one—at other times another. In essential hy-

pertension there is discoverable no tissue lesion. Yet if the hypertension exists long enough fibrotic tissue alterations invariably take place in heart, arteries, brain, liver, and kidneys. These cases are mostly busy, keen male workers, who do everything 'hard' especially physical or mental work, exercising eating, drinking, smoking and other indulgences. The ratio of female cases increases as women lead similarly tense lives. A second group of hypertonics appear where primary changes are in arterial wall and gradually involve kidneys and heart. The third group are the primary nephritis cases with cardiovascular fibrosis trailing along. Then there is the fibrosis or sclerosis of old age which does not always wait until old age to develop.

"There are two kinds of years, calendar years and tissue years" (Townsend). Longevity is a vascular affair. It depends upon the tubes transmitting the vital fluid to all tissues, and the heart muscle the propelling engine. Fibro-degenerative changes in the "vital rubber" of the walls depend upon the inherited quality of the rubber or the wear and tear to which it is exposed. That inheritance plays some part is evidenced by family groups who develop early cardiovascular disease, without relation to any other known cause. Poor material must have been used in the construction of the engine or the tubing or both. Aside from these cases the usual cardiovascular disease results from the bad use of a circulatory apparatus constructed of materials of first quality.

Perhaps the first question in prevention is should members of families with numerous case-records of early deaths (at 25-45) procreate? This is a wide open question. Cardiovascular disease is usually transmitted by criss-cross inheritance where the sexual powers (not desires) are fairly balanced. (Sons of sclerotic mothers and

DIPHTHERIA OF THE SKIN

ISIDORE PINCUS, M D, *New York City*

There have been few reports of this rare condition in this country,^{1,2} with an excellent summary of the literature by Knowles and Frescoln. The types of skin involvement by the Klebs-Loeffler bacillus can be classified into three groups, (1) Cases characterized by false membrane production, (2) Cases characterized by one of many dermatologic lesions as bullae, vesicles, pustules, etc with no characteristic clinical picture, (3) Cases of wound diphtheria.

The case herewith reported is interesting from two aspects. It is one of the false membrane, paronychia-like types described in the European literature³ but not reported here. Then, it remained undiagnosed for eight weeks, was admitted to a leading general hospital, had an incision done on an enlarged cervical gland, remained a week and was discharged with no thought of diphtheria in the minds of the staff.

Case Report

I W, female, five years old, seen at home February 19, 1937, complaining of fever, generalized itching eruption, paronychia-like lesions of the fingers, and bloody nasal discharge.

The child had recently come from Germany, and became ill one week after landing. The first symptoms began about December 23, 1936 with a slight bloody discharge from the nose, an increasing swelling of a gland on the left side of the neck, and fever of about 101–102°F.

She was treated by physicians at home until January 11, 1937 when she was sent to one of our leading hospitals for incision of a deep cervical adenitis, as it was described. A smear and culture taken from the throat only showed a hemolytic streptococcus. As far as could be determined no pus was found in the gland. At this time the child had a lesion at the base of the nail of the right thumb.

At the time of discharge on January 18 she still had some fever and was still sick. Thereafter, the patient was seen in the pediatric clinic of the hospital. The right index finger showed the same lesion as the thumb and a little later the left index finger became involved in the same way. The diagnosis of fungus infection was made and a keratolytic ointment used which aggravated the condition and was soon stopped.

On February 14, the patient developed a generalized itching eruption, a higher temperature, and was seen by the author five days later.

At this time, the temperature was 103.5°F. There was a generalized urticaria. The nares showed bloody crusts and a profuse bloody mucous discharge. The throat showed pharyngeal and tonsillar congestion.

The fingers showed a most interesting picture. On the skin at the base of the nail enumerated above was a gray white membrane about one cm in its largest diameter slightly raised above the surface of the skin. It was moist, surrounded by a bright erythema in which were some pinpoint superficial vesicles. The nails of the fingers involved on the right hand were furrowed thinned towards the base while the left index finger nail showed no involvement. There was no pain or tenderness on pressure and no adenopathy around the elbows or axillae.

About five cultures were made from the finger lesions traumatizing the membranes and two cultures from the nose.

The origin of the urticaria probably was toxic as no history of antitoxin injections was elicited. An injection of five minims of adrenalin immediately relieved it. The next day the temperature was down to 100.5°F and the urticaria was much improved.

The Board of Health laboratory reported positive cultures from some of the finger smears and from the nose. A virulence test of the culture from the fingers was started and reported later as a virulent organism.

A photograph of the fingers was taken, but unfortunately was unsuccessful.

After consultation with Dr. Wilfred C. Hulse, a pediatrician, it was decided to give antitoxin 5000 units, to the child and to use potassium permanganate soaks (1:5000), $\frac{1}{2}$ hour 3 times daily to the fingers.

Under this regime the bloody nasal discharge stopped the next day, the fingers made remarkable gains, the temperature became normal two days after the antitoxin and thereafter there was an uneventful recovery.

It was later found that the pediatric ward of the hospital was quarantined, and showed four diphtheria carriers.

pressures) should be encouraged to remove to or visit altitudes of five thousand feet or more

Now what can be done in realistic prevention by demolishing, excluding, or correcting known positive causes? First comes syphilis, the most important single cause. Therefore the rapidly-developing campaign against syphilis should have preventive implications in proportion to its other attainments. Active syphilitics in any stage may produce syphilitic children, although many are born and grow to maturity with apparent good health and negative Wassermanns. Cured or long-lasting arrested cases may not only produce healthy offspring but the numerous miscarriages credited to the disease are abolished in some series, largely reduced in others. We are proud to note that the present campaign to control syphilis was born in New York State when Surgeon-General Parran was our Health Commissioner and that our Society Council co-operated with him actively through the efficient Public Health Committee. Continued cooperation in State and Nation is our duty.

Some States require negative Wassermanns or Kahn tests from each candidate for marriage. If scientifically done this is a laudable effort in prevention and should be encouraged. It goes without saying that active syphilitics should not marry. What other measure can be more effective? We understand that such a law will be proposed in the next State Legislature. Its provisions should be carefully studied by all licensed physicians.

Pregnant women who have had repeated miscarriages or whose husbands have a history of syphilis should receive active antisiphilitic treatment throughout gestation whether Wassermann tests are positive or negative. All children of such offspring should be followed up observantly. Thus much cardiovascular disease may be prevented by destroying or reducing syphilis.

Diabetes produces much cardiovascular disease primarily through arterial changes. Hence the prevention and early and continued control of diabetes by the modern balanced diet and insulin is an important preventive of the secondary conditions.

Most of the balance of cardiovascular patients can be found in one of two groups or in both, namely (1) those who overwork one or more structures or functions and

(2) those who poison themselves from without or within. Besides the stress and strain of overworking physically or mentally, denying themselves the physiological rest required by any normal human (and rest requirements vary), these patients are apt to overwork everything they have or use physiologically. They may be overeaters. Overworking the digestive tract and functions is a notorious cause of cardiovascular disease. The mills of the Gods grind slowly but

" (you know the rest of it). Overworking the liver is a companion error. If overworking is by shovelling in the starches and sugars or the intake of excess fats, the liver functions, digestive, metabolic, and storage are overtaxed. Cholesterol, urea, and other things spill over into the circulation intolerably and this does vicious things to heart and arteries. Likewise the kidneys can be overworked by errors in volume of intake and in the chemistry of food and drink. You see the two groups (overworkers and poisoners) merge in spots. The renal cases of cardiovascular disease are always subjects of debate. The only conclusions available are that sometimes nephritis is the primary element in cardiovascular disease whereas in others the heart and arteries yield first to stress or toxemia. Excessive intake of nitrogenous food causes some primary renal irritation, also large consumption of chlorides. To prevent nephritis by reducing these excesses most patients should begin about thirty or forty years before their physician advises these reductions as *therapeutic measures*. This may also be wise in the cases where the cardiovascular disease is primary. We shall be more competent in preventing both types when we understand more about their origins and cognations.

Besides overworking the mind and functions generally, overworking of the voluntary muscles brings increased peripheral resistance, elevates blood pressure, and crowds the heart muscle, hence hypertrophy and defective nerve and nodal impulses. We should warn our patients regarding excessive muscular work, especially the extravagant young athletes who do not usually enjoy longevity. This statement needs some qualification which however carries us still deeper into preventive work. Some research has been done in the recent past on crew men in college, which seems to indicate that this extreme form of exercise is

daughters of fibrotic fathers) Where there are mostly or all sons of sclerotic fathers, sound cardiovascular systems may be the endowment of the offspring Or when mostly daughters of sclerotic mothers The difficulty is that statistical evidence indicates that balance of sexual power also in some measure determines sex Thus if father is sclerotic and more highly endowed with sexual power more daughters arrive who are most likely to suffer and die early Likewise mother and sons Moreover young couples at the ages in which procreation is richest are not thinking in terms of ultimate consequences Nevertheless we have all seen the sufferings and tragedies of young men and women perishing from an acute or sub-acute cardiovascular disease and have not only pitied *them* but also their offspring Contrarywise *some short lives* prove extremely valuable in varying ways What to recommend is open to careful consideration and broad discussion It deserves careful thought in its physiological, social racial and spiritual aspects Nature is notoriously so careful to provide lavishly for procreation that wisdom and conscience should come into play whenever any suggestion is made to interfere with her plans for repopulation Physiologic and social consideration are secondary—and crass emotionalism is barred

The outstanding negative or subtractive cause of cardiovascular disease is anoxemia Recent researches have led to the conclusion that subnormal supplies of oxygen extending continuously or in installments over long periods are effective causes of cardiovascular disease These subnormal supplies of oxygen are not fixed on supply or demand sides The supply may be normal at times and subnormal at others according to the type and degree of interference The demand will vary with the activities of the combined functions of being During periods of comparative inactivity a normal supply of oxygen may be received through obstructed nasal, pharyngeal, laryngeal or bronchial viaducts With moderate or extreme functional activity oxygenation may become decidedly subnormal Here preventive measures aiming to eliminate or reduce such obstructions are always in order Here the question is do we often look for such causes of faulty oxidation and therefore of cardiovascular disease? Chronic irritation of nasal

mucous membranes from daily smoking may do this We often see a smoker, cigarette or cigar in mouth, busy with both hands, trying to overcome dyspnea by dodging smoke and shifting cigarette or cigar, and yet he can hold on some minutes before he gives up and tries for a compensatory intake of oxygen

Habitual physical inactivity may reduce lung capacity in time and cause chronic subnormal oxygenation Thus if a person's occupation does not demand moderate activity a certain amount of daily or twice daily exercises are indicated The habit of taking full breaths and exhaling to a full degree in fresh open air, is preventive medicine especially for sedentaries For these also lessons and practice in singing are good preventive measures

Is there any worse ordinary combination making for anoxemia than sitting in the low seat of a closed motor car, consumed with anxiety over a critical case, while you hold your breath driving through crazy traffic, smoking a cigar, cigarette, or pipe? Elevate the seat, open the windows or drive an open car, think only of driving, avoid all traffic possible, and omit smoking Thus you are practicing preventive medicine

Without further comment we can assume that inadequate ventilation of homes, schools, factories, offices, and public halls and audience rooms causes varying degrees of oxygen starvation as well as carbon dioxide poisoning! Remember the "Black Hole of Calcutta" story!

Specifically the term anoxemia has been used as a synonym for mountain (or altitude) sickness This involves consideration of low atmospheric pressures and the physiologic results thereof The preventive and curative treatments are known to you all "Aviators sickness" also depends on low air pressure Preventive medicine here should include physical examination of those proposing to remove to altitudes two thousand feet or more above their present habitat (Extreme conservatism is advisable because we have known of residents at sea-level to remove to an altitude of two thousand feet and perish all too soon from a mortal feature of an unsuspected cardio-vascular disease) Those thus physically examined should be thoughtfully advised. Only those who possess normal hearts, negative electrocardiograms, and at least moderate blood-pressure (including moderate pulse

chewing finecut or plug? Whatever the manner of indulgence the use of tobacco is a fascinating habit. Whatever other harm it does or does not do it is a cardiovascular enemy through oft repeated spurts of hypertension or a continuous performance thereof. To cease its use after years of indulgence demands character of unusual quality and dimensions. Yet most tobacco users should quit or reduce it largely after fifty. Therefore to surely prevent its cardiovascular consequences, persons should avoid beginning its use.

The average cup of moderately strong coffee contains approximately three grains of caffeine. We should instruct our patients to take coffee in proportion to its caffeine content, their need of its stimulating action, and their ability to use it. The person who discharges much physical energy can profit largely by its steady moderate use. The sedentary bookkeeper, clerk, typist, student, or scholar can safely tolerate small doses only. Temporarily he may do wonders for a few hours after stimulation but it is materially expensive. Coffee is a cardiovascular poison. Its use should be regulated by reason or avoided.

Tea contains some caffeine but is comparatively nontoxic to the cardiovascular system when imbibed as a mild infusion. Strong and boiled over varying periods, it is definitely harmful. The tea-pot cooking all day on the stove produces other vicious poisons and can produce various chemical changes in the human body including some that encourage cardiovascular lesions.

Some credible authorities state that tea and coffee topers harm themselves as definitely as the hilarious alcoholic debauchee. Reasonable restraint or complete abstinence will in a degree be preventive medicine in circulatory disease.

Internal poisons in substantial array may justly be credited with causing or assisting to cause cardiovascular disease. First and foremost, gastrointestinal fermentation, putrefaction, with spastic or atonic types of constipation result from insufficient mastication, hasty eating, lack of exercise and inattention to colon. Two or three decades of daily autointoxication can do as much harm as alcohol to the aforesaid engine and tubes not to mention other structures. In fact, many constipated sugar eaters manufacture their own alcohol. As physicians we should see that our patients

are provided with teeth to masticate with, that they understand what chewing does for them, that their diet is adjusted to their gastrointestinal and other needs, and that they know all of the meanings of the word "constipation." Evacuations must not only be daily but also adequate, of proper consistency and color, and free from undigested food or mucus. We have unpacked many a colon full of hard dry feces in patients who thought they were not constipated because of "some evacuation" each day, while enemata have relieved many others of unbelievable numbers of hard marbles, indicating long storage and petrification. Preventive measures here again indict the need of broad educational endeavors and much personal work among our patients.

Focal infections unquestionably play a leading part in promoting cardiovascular disease. This is a scintillating reason for periodic health examinations. Insidious low-grade chronic septic poisoning effectively produces hypertension and cardiovascular disease. At every periodic health examination, we should look for infections of sinuses, tonsils, teeth, gums, bronchi, gall-bladder, skin, appendix, the prostate in males, and reproductive pelvic viscera in females. Pyelitis and cystitis should be excluded by at least microscopic search of urinary sediment. If there is any degree of chronic osteoarthritis our search for focal infection should be intensive, for associated cardiovascular disease and arthritis may arise from common septic source. A former classmate of Rosenau once accompanied us to the experimental farm-laboratory in Rochester. Introductions over, Rosenau turned to our companion and asked "What are you here for?" The reply was "Hypertension—180 to 200." "Well, where's your focus?" said Rosenau. This question should always jump into the limelight of our minds whenever hypertension is found. Chronic sepsis is not always discernible or present. However it may be associated with one or several other causes. This brings us back to Turner's declaration that everything has a cause and the cause of anything is everything."

We know intimately a physician who has chronic sinusitis, two diseased tonsils, some dead teeth, a generalized osteoarthritis, and cardiovascular disease. Useful men and women should not be allowed to keep such teeth, tonsils or sinuses or arthritides and

followed by hypertensivity of the heart only when some other cardiac damage of unsuspected nature exists, usually chronic infection. If this be true in rowing, it is doubtless true in all other overexercise. All the more reason, then, that those infective states that can in any way damage a heart muscle should be prevented by appropriate means in childhood.

Many overworkers are also poison cases whose metabolic rates are high due to overactive thyroid glands. The emotional drive, mental activity, and the constant struggle to tug and spurt wears the cardiovascular system. Failure in restoring these patients by operation is often due to the persistent daily damage of thyrotoxicosis over a long neglected or untreated period. The engine and tubes have lost their strength and resiliency. Cardiovascular disease is permanently established. Early removal of most three and four plus toxic thyroids is therefore a measure tending to prevent it.

Now we are over in the "poison" column of causes. The leading intake poisons are lead, alcohol, tobacco, coffee, and tea. Exactly how they operate harmfully is far from settled. Sensitiveness to the action of each varies among different persons and in the same person at different times of life and different circumstances. We see more acute lead poisoning in painters, glaziers, and plumbers who are young. Workers in lead however mostly develop cardiovascular disease in the fifth or sixth decade and are long time chronic cases. Lead commonly clings under nails or in the folds of the hand covering and is swallowed in tiny fragments while eating. Prevention can be almost assured if nails are kept short, and hands are scrubbed with stiff brush, soap and water, then the nails cleaned with a cleaner, then hand re-scrubbed, and well dried. As lead can readily be absorbed by lungs masks are advisable for lead workers in factories. Frequent general baths contribute largely. Of course we are thinking of the chronic occupational or habitual absorbers. Chronic lead poisoning may occur through drinking water settled for some hours in lead pipes or for a longer time in lead-lined cisterns. Diminishing use of lead water pipes is therefore preventive—and cisterns should be lined with something less soluble or nontoxic. Cider and other alcohols with acid content rapidly dissolve lead in contact. Lead in cosmetics and hair-dyes

may be absorbed by skin. False-teeth and certain types of thread contain lead ready for intake. The preventive measures are obvious. Most of the acute cases are accidental and have little to do with our subject. However the prevention of lead poisoning is of itself an interesting theme. Its relation to cardiovascular disease is important, however dark and dull it may appear.

More sparkling is the subject of alcohol. While there is no question concerning the resultant hypertension and the malicious overaction of heart muscle and degenerative changes in viscera attending its daily consumption over a period of years, there are many elderly life-time drinkers who seem to be preserved in it, especially if they have avoided overeating. Moreover people seem to develop cardiovascular crises more rapidly when they begin its consumption in the fourth or fifth decade. We recently sat next to an eminent cardiologist at a terrace-table outside a golf-club. "Should that jolly fellow with a florid face drink so much gin?" we asked. "No," said the doctor, "he had a coronary thrombosis three years ago. He should stick to Scotch in small doses largely diluted with an alkaline water. That would dilate his arteries and do him good." This seems to be prevalent opinion with cardiologists. The favor with which the old-fashioned nightcap is regarded by excellent physicians as fatigue reliever and therefore hypnotic must also be respected. (Lauder Brunton). Nevertheless the habitual use of toxic doses of concentrated alcohol daily over years produces cardiovascular disease. It should be interdicted as a habit.

Tobacco contains nicotine, a most virulent poison. It also contains several other poisons in minute doses. In general its deleterious actions are recognized and accepted. The majority of men perishing from coronary disease have at some time been habitual users for years. In the 'gay nineties,' "tobacco heart" was a clinical entity of importance. The newer clinical pathology has demonstrated that most influences are arterial, including coronaries. A personal communication from a New York Hospital clinician stated that observations demonstrated a rise of from six to ten points in blood-pressure after four puffs of an ordinary cigarette. The temperature changes in extremities are well-known. What then about the big black cigar, the fragrant pipe, and

to their own disadvantage. If we could fool them we would help them. But in Dora a cold compress over one eye had an immediate and permanent effect. She was sure that the right upper lid was shaking badly. She "felt it only" and did not see it in the mirror. Nor could the examiner notice any kind of a tremor, or nystagmus, or anything abnormal in the eyes or in the fundi. The vision was also adequate. Nothing abnormal as far as general physical health. But the mental make-up was quite irregular. It had a kink somewhere, but no classification or diagnosis was possible. As some psychiatrists say, a psychopathic personality without psychosis. I learned from her family that she was always a "pest" and everybody was afraid of her. I was prepared to begin a series of talks with her and to go to the bottom of the problem. The hour, however, was late and I was tired. So I told her about the cold application, which would have had a meaning in some real inflammation. I must have impressed her more than I expected. She went home and had the compress on for one half hour, and, she claimed—and the entire family proclaimed—that the "shaking" which had lasted "continuously for weeks," was gone never to come back, and she stopped complaining.

"It was miraculous," she told me.

But when I proposed the water treatment, she balked at first. "What with? Water only? There is nothing to water!"

To which I retorted "Nothing, eh? Have you ever made a drop of water?"

Water and watery remedies are certainly miraculous in the right person in the right time.

Unnecessary or harmful drugs, which may suggest a mental cure, may, at the same time, have the disadvantage of injuring the body physically. Did not our old German teacher warn us to avoid prescribing indiscriminately and only because a medicine is stylish? He made fun of those in the profession whom he called medical parrots.

*"Wenn man nicht weiss wie, was warum,
Gibt man Kalb Jodatum"*

And some time in the last century, when quinine was strongly entrenched as an all-around medicine, a famous physician seeing that it did not work, dared to substitute arsenic for it. But his colleagues were tearing their beards and called him a criminal. At a scientific meeting he told them that—as Raphael of old said about his art that all paint must be mixed with brains—so in our art all medicines were mixed with suggestion and when an accusing finger was pointed at him "What will you say to God when summoned before Him?" he replied "I will touch his shoulder friendly and tell him, Old Pal, you don't know anything about this."

NEW MEDICAL BUILDING AT SYRACUSE

Dr Ray Lyman Wilbur, president of Stanford University and former Secretary of the Interior, will be the principal speaker when Syracuse University dedicates its new \$825,000 home of the College of Medicine on Nov 22.

Other speakers will be Dr Henry A. Christian, Hersey professor of theory and practice of physic in College of Medicine of Harvard University and Dr Edward S. Godrev, Jr, commissioner of the New York State Department of Health. Dr Wilbur

is chairman of Council on Medical Education for the American Medical Association.

The new five-story medical building is the fourth unit to be completed in the plan initiated in 1925 to construct a hospital and educational center adjoining the Syracuse University campus. Previously completed units are the Syracuse Memorial Hospital, the State Psychopathic Hospital and the City of Syracuse's Communicable Disease Hospital, all of which are affiliated with the College of Medicine.

The next American Board of Obstetrics and Gynecology examination (written and review of case histories) for Group B candidates will be held in various cities of the United States and Canada on February 5, 1938. Application for admission to these examinations must be filed on an official application form in the office of the Secretary at least sixty days prior to these dates.

The general oral, clinical, and pathological examinations for all candidates (Groups

A and B) will be conducted by the entire Board meeting in San Francisco, Calif., on June 13 and 14, 1938 immediately prior to the meeting of the American Medical Association.

Application for admission to Group A examinations must be on file in the Secretary's Office before April 1, 1938.

For further information and application blanks address Dr Paul Titus, Secretary, 1015 Highland Bldg Pittsburgh, (6), Pa.

they should be discovered by us at periodic health examinations. Just so with the other causes. *This is our extensive obligation.* If we start now and work diligently for a few decades coronary deaths and cardiovascular disabilities may be reduced as rapidly as has the mortality and morbidity from tuberculosis since 1900.

Considering the notorious incidence among physicians we might well begin by preventing these vicious killers in the medi-

cal students and hospital interns of today and in the young practitioners by periodic examinations. Let this be a part of their training.

If we do this for each other and thus reduce the incidence among ourselves, publication of records may interest the people at large. Thus through periodic health examinations and abiding by their indicated care we may prevent much of the now increasing cardiovascular disease.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., D.R.P.H., New York City

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Some Easier Cases

CRESCENDO

A man was refused a second insurance because his *blood pressure* was 160, slightly higher than normal. That made him worry. He lost his appetite and sleep and much weight. He was in bad humor and made his family unhappy. After a while his underweight suggested "cancer" to him. He read up on health, counted his pulse, palpated his heart, looked into the mirror at his eyes and tongue. Avoided friends and canceled all invitations. Neglected his business and was financially all but ruined.

He went so far as to pay attention to the smallest detail. "The doctor in Chicago said I was improved, but what is the use? My blood pressure is still five points above."

I had to explain how ridiculous this statement was and also how much better it would be for him not to know about himself. Then he caught me contradicting myself. Had I not done my share in popularizing health and had I not taught the necessity of knowing one's body? I was placed in the defensive. The *gnōthi seauton* of the Greeks, the Latin *nosce te ipsum* is meant for normal people and should not be taken literally. Also it should be understood in a detached way. To know oneself too much can only bring harm—and ignorance. It is like trying to see the elephant through a magnifying glass and the mountain very close and without a perspective.

Psychoneurosis, especially when made worse by mental depression, is like the increasing power of slander, the best, the most wonderful description of which is in Beaumarchais' "*La calomnie, monsieur?*"

An eloquent explanation of the point of

view of the insurance company which is buying him as goods and cannot be sure how he might endanger his life in the future, opened his eyes. That was compared with the viewpoint of the private doctor who knows what life he leads and for whom this slightly increased blood pressure, in the absence of other physical defects, plays but a scant role. Patient was gradually talked out of all his disease entrenchments and convinced that he was practically healthy.

MISLEADING LITERATURE

A young man, recently married, was depressed and mentally upset because he thought himself impotent. He had read a big book on sex relations and what impressed him more was the explanation on the "position" at the intercourse. He was in need of some enlightenment, but there was too much of the good, too many and unnecessary details were given. While trying to imitate some of the descriptions, his partner objected. Naturally, any remark—and the more prosaic or trivial the worse—during the critical moment has a deleterious effect. He was told that such *temporary lack of adjustment* did not mean impotence and that it was best to *follow no author*, but his instinct—and hers, *not to be excessive, not to suggest impotence to himself* and not to let his wife *humiliate* him.

He was easily cured, because he had not been ill.

PLACEBO

Placebos do not always work. Patients, especially psychoneurotics, are too smart—

adolescence to obsolescence" without realization of its rich potentialities? To Dr Van Etten, as to many other thoughtful practitioners, a partial answer lies in more vigorous exercise of their social influence and political powers by medical men

Right and Wrong Ways

Because of her official status in public health work, Miss Josephine Roche's recent address before the American Public Health Association has naturally been searched for hints of Administration policy. The result is highly disquieting to the medical profession. While Miss Roche does not actually say state medicine, all the implications she makes point that way. Her demand for concerted public action under the leadership of the United States Public Health Service ignores the enormous contribution made to American health by the private practitioner of medicine and his unique fitness to help direct medical policy.

Miss Roche's attitude is typical of what the profession—and the public—have to fear in lay political control of medicine. Her whole medical philosophy, like that of a majority of social workers and bureaucratic administrators, is based on extensive statistical computations which do not truly reflect individual needs. The nation's medical requirements cannot be expressed in a statistical average or supplied by a standardized formula.

In the last analysis, excluding mass measures like sanitation and the control of contagious disease, medical care is essentially a matter of individual service by individual physicians. Experienced health officers and private practitioners agree on this. Aware of the stultifying effects of bureaucratic control on medical initiative and judgment, they hold that the best safeguard for national health lies in the private practice of medicine carried on in close and active cooperation with local public health

In view of the rest of her speech, Miss Roche's request for a special committee of the American Public Health Association "to co-operate with the United States Public Health Service" in the expansion of public health work might easily be construed as an invitation in the direction of state medicine. The Association refused this invitation without repudiating any of its benevolent aims by appointing a committee "to cooperate with the United States Public Health Service, the American Medical Association, the American Dental Association and other appropriate bodies." The Administration would do well to follow this example.

Treating a Cold

The season of the year is at hand when the common cold will once again begin to play its role in the production of upper respiratory infections. In itself, the cold and the symptoms it presents, are not the products of the ordinary pathogenic organisms, since these are not recoverable in cultures taken during the first days of the disease.¹ Rather the latter function as secondary invaders which produce a subsequent infection of the mucosal lining of the nasal chambers. It is this secondary infection which presents the danger of the common cold in the incidence of pulmonary, otic and nasal accessory sinus suppurations. Consequently the treatment of coryza should be directed toward either preventing or limiting the duration of the bacterial infection.

All of the treatment at present in use is more or less empiric in nature. Diehl,² however, has found that a combination of codein sulphate and papaverine hydrochloride, $\frac{1}{4}$ grain each, when administered for ten doses over a two day period immediately after the onset of the cold resulted in definite relief in ap-

The Doctor Asks "Where?"

In an outspoken address before the Bronx County Medical Society, Dr Nathan B Van Etten graphically described the modern doctor's dilemma. Criticized by social agencies which hope to usurp his functions, bound by ethical laws which place the public welfare above his profit, threatened by political domination, how is the physician to continue his traditional service without sacrifice of his professional independence and security?

Obviously the fast changing conditions of modern life require correspondingly rapid adjustments on the physician's part. The emphasis in modern medicine has shifted to a marked degree from cure to prevention. The forward looking practitioner must seek new fields to replace those which medical progress has removed and will continue to cut from his domain.

Encouraged, perhaps, by the worldwide growth of totalitarian trends in government, politicians in this country have begun to turn covetous eyes upon the practice of medicine. So-called social security furnishes an attractive cloak for a multitude of sins. Not the least of these is encouragement of the delusion that compulsory sickness insurance would

furnish better medical service for all the people at lower cost.

As Dr Van Etten states, "The practice of medicine is concerned with three classes of people: the indigent, the large middle class, and a small group of people who may be called independently well-to-do. *All these people are better cared for in the United States than anywhere else.* Health insurance schemes abroad do not take care of the indigent, have not reduced morbidity but have reduced physicians to a very low place in the social scale."

This is fact, not unsupported theory. Indisputable proof is found in international vital statistics, which place American health services on the basis of morbidity and mortality rates, far ahead of those in nations relying on obligatory insurance for medical care. If further substantiation is wanted, it can be found in the diminution of individual research in insured countries as compared to the vigor and productivity of private scientific investigation in the United States.

Nevertheless, American medicine is harassed by politicians and lay sociologists who see in compulsory sickness insurance an opportunity to control a vast and enormously profitable bureaucracy. What can physicians do to prevent the transition of their profession "from

CURRENT COMMENT

"TO MY MIND IT WOULD BE highly desirable, and is more often possible than we are in the habit of believing, for a youngster who knows, as many of them do during his high school years that he proposes to practice medicine to begin at that time to study the question of what type of practice he will undertake. By coming to this decision by the time he enters college he will be able to obtain some acquaintances with philosophy and psychology, economics and sociology. These seem to me of real importance. His time in the medical school will probably necessarily be spent much as that of his brethren but his internship should be of longer duration than field and should be of longer duration than has generally been thought requisite equipment for general practice. It has been the habit in the past to allow students to go out into general practice with the confidence that they can fill the bill after one year of ordinary internship. Yet it seems to me implicit that the general practitioner must be a more broadly educated person than the specialist, and I do not believe that he can fill the berth which will be required of him in the future unless he has two or three years in contact with masters after his formal medical course is finished."

"—Hugh Cabot writing of Hurdles for Young Doctors" in the autumn issue of *The American Scholar*

profession"—Harry Roberts writes anent euthanasia in *The Living Age*

"MERCIFUL KILLING, NO MATTER HOW humanely applied, would demoralize society. Like war and capital punishment, it would revive the dormant sadism and destroy the sacredness of human life."—A. A. Brill's opinion in regard to euthanasia, as quoted in *The Digest* of October 23

"WE ARE PASSING THROUGH a phase of superficial liberalism. The term liberalism is applied in all departments of human activity and in all the disciplines of knowledge. It has a special significance as applied to political action and political theory. In this field we often use the term as applied to individual experience. Most men combine both progressive and conservative senses. Liberalism represents a personal attitude so combining these senses that the individual is constantly prepared for evolutionary change. "But liberalism also refers to a political tradition. This tradition rests upon certain principles. Two are of cardinal importance. Human advancement both spiritually and materially, depends upon the freedom and liberty of the individual, and however desirable any economic and social change, it should not be sought by means that infringe upon personal liberty."

"DOCTORS ON WHOM WOULD FALL most of the responsibility for administering the *coup de grace*, should euthanasia become general and legal, are perhaps the least enthusiastic advocates, not from lack of sympathy but because they know better than does the public the sinister possibilities attendant on the giving of increased licenses to less reputable members of their

"The outposts of liberalism reach into all frontiers of social and economic ideas. They strike camp with each new sunrise. But its citadel holds a treasure dear! Bought, the blessings of civil liberty. The lines of proposed advance should not be so drawn as to weaken its defense."—James L. Nesbit in an excellent letter to *The New York Times* of October 24

COMMITTEE ON WORKMEN'S COMPENSATION

Physicians who have removed their offices since obtaining a registration card from the Industrial Commissioner, who engage in Workmen's Compensation practice, are requested to send the change of address to the office of the Industrial Commissioners, 80

Centre Street, New York City, and to the County Society which qualified them. This matter is of great importance and should receive the immediate attention of physicians involved.

DAVID T. KALISKI, Director

The wives of the doctors of the Wyckoff Heights Hospital in Brooklyn have organized the "Guild of Wyckoff Heights

Hospital," for the purpose of furnishing a social service worker to follow up cases after they leave the hospital.

proximately three-quarters of all cases treated. A decrease in the nasal discharge and congestion was evident early in the treatment, and the incapacity of the sufferers was reduced to a minimum.

Whether this combination of opium derivatives acts synergistically on the vasomotor system or on the peripheral vessels is not definite. However, their inhibiting action in the prevention of the secondary, infective stage of the cold when they are employed early in the course of the disease, is important to bear in mind in our attempt to avoid the severe complications which follow in the train of acute coryza.

Myocarditis and Vitamin B

More and more, as our knowledge of the role of vitamins continues to increase does our conception of clinical medicine become clarified. Hitherto obscure conditions, for which we had no rational therapy, are now amenable to definite regimes which result in cures or at least amelioration of the existing disease.

The role of the vitamin B complex in relation to beriberi, with its fully developed clinical picture of edema, multiple neuritis, and cardiac weakness has been a recognized etiological factor for many years. Recently, however, certain neurological and cardiac lesions for which formerly no satisfactory explanation as to cause could be found, are now being recognized as partial or subclinical forms of beriberi. Alcoholic polyneuritis, certain forms of acute psychosis and of anasarca are among these.¹

Weiss and Wilkins² have studied 125 cases of so-called myocarditis which presented gallop rhythm, tachycardia or bradycardia, dyspnea, pulmonary congestion, and cardiac dilatation. They present evidence that the pathological

findings in this series are identical with the myocardial degeneration found in beriberi. Such a lesion, they feel can arise in cases of malnutrition and in vitamin B deficiency such as occurs in thyrotoxicosis or prolonged febrile states. On the clinical side of this problem, Jones and Sure³ administered diets rich in vitamin B, to cardiac patients and found that the management of these cases was easier and the results obtained were far better than any other in their experience.

The fact that cardiac disease ranks as one of the foremost in the cause of death makes these contributions among others welcome in pointing the way for a new therapeutic attack. Heart disease of known etiology must be treated by measures now in general use, but cases of myocarditis wherein the cause is not evident may be found by keen clinical investigation to be due to avitaminosis and to respond favorably to vitamin B therapy.

"Should He Have Died of Heart Disease?"

This title prefaced the Presidential address to the Third District Branch Meeting at Kingston, September 30.

Dr. Goodrich, whom we all know as an eminent surgeon, presented a notable medical paper upon the causes and preventive measures to lessen the incidence of heart disease. The thesis continues his program of stressing preventive medicine.

It is not our purpose to editorialize upon the address but we can hardly avoid commenting on its timeliness, its simple stress upon avoidable factors in the production of heart lesions, and draw attention to its appearance elsewhere in this issue. All of us will benefit by reading this presidential address on page 1939.

dent Mrs Francis Irving presiding. Twenty members of the board were present, having been entertained at dinner and bridge by Mrs John L Bauer on the evening before the meeting.

The members present were Mrs Francis Irving, Mrs Daniel Swan, Mrs Frederic Elliott, Mrs Luther Kice, Mrs Henry Hirsch, Mrs Edgar Neptune, Mrs Edwin A. Griffin, Mrs Louis A VanKleeck, Mrs John J Buettner, Mrs Horace M Whiteley, Mrs James M Dobbins, Mrs Harry P Mencken, Mrs John W Mahoney, Mrs Albert W Bell, Mrs Walden Retan, Mrs John L Bauer, Mrs J Emerson Noll, Mrs William Barnhardt, Mrs Carlton M Potter, and Mrs Milton B Bergmann.

At the meeting, reports of activities were presented from various sections of the state. Outstanding during the past summer were the achievements of the Onondaga Auxiliary which sponsored a Maternal Welfare Campaign and of the Suffolk County Auxiliary, equipping the infirmary donated by the Suffolk County Medical Society to the Boy Scouts camp at Bating Hollow. The following resolutions presented by Mrs Frederic E Elliott, Chairman of the Program Committee, were adopted:

WHEREAS, It is the purpose of the Woman's Auxiliary to the Medical Society of the State of New York to bring about understanding between the profession and the public, and

WHEREAS, It is the purpose of the Committee on Program to assist the County Auxiliaries in making their programs, and

WHEREAS, A stronger organization in the department is necessary to obtain best results

Be it Resolved

First, That each County Auxiliary have an active Program Chairman

Second, That each County Chairman of Program familiarize herself with the Presidential address of Dr Charles H Goodrich "The Partnership Idea in Public Health" (N Y STATE JOURNAL OF MEDICINE, August 1, 1937, page 1397)

Third, That each County Chairman of Program secure from her County Advisory Board definite instruction as to how her County Auxiliary may serve in bringing about Dr Goodrich's idea of Preventive Medicine

Fourth, That each County Chairman study the Woman's Auxiliary Handbook, that she represent on her program every function of the Auxiliary—Social, Philanthropic, Legislative, Educational, and Public Relations"

Mrs Bauer entertained her guests at a luncheon at the Golden Eagle in Bayport, followed by a drive which included a tour of Cathedral Pines and other parts of Long Island.

In the evening the guests assembled at dinner dressed for a party as of the "Gay Nineties"

Since that meeting several of the county auxiliaries have been quite active.

CAYUGA COUNTY The Auxiliary met on October 21 at the Nurses Home of the Auburn City Hospital. Dr W E Weld, President of Weld College was the main speaker, his topic being, 'India and the Life of Gandhi'.

JEFFERSON COUNTY An organization meeting was held in Watertown on October 19. The President, Mrs Francis R Irving, was present and helped to work out plans for further meetings.

KINGS COUNTY A card party was held to raise money to buy books to be presented to the library of the Kings County Academy of Medicine.

Layettes were presented to this Auxiliary, which in turn will be given to any person or society that the board may designate.

Mrs Edwin A Griffin, President, writes:

This Auxiliary in age is hardly out of the nursery stage, but many of our members have long years of experience as the humble wife of the physician to her credit—that unseen person who hears all the ills of the poor old world—who answers the phone day or night and tries to comfort the distracted patient on the other end of the wire—is ever alert at the side of her husband to give to the public the best she and the good Doctor have to offer. Surely no one is better fitted to be an aid to the medical profession than the physician's wife.

THE WOMAN'S AUXILIARY

To the Medical Society of the State of New York

Officers (1937 to 1938)

President, MRS FRANCIS R IRVING, 119 Wendell Terrace, Syracuse

President-Elect, MRS DANIEL J SWAN, 141-54 Northern Blvd Flushing

Advisory Council from the Medical Society of the State of New York

Dr John L Bauer, *Chairman*, Brooklyn, Dr William H Ross, Brentwood, Dr Herman W Galster, Scotia, Dr William A Groat, Syracuse and Dr Daniel Swan Flushing

Mrs John L Bauer, former President, writes "It is very satisfactory to learn that the Woman's Auxiliary to the Medical Society of the State of New York has been granted space in the NEW YORK STATE JOURNAL OF MEDICINE, and we are duly grateful to those who have made this possible. It is the fulfillment of a desire and we feel confident, will prove worth while, not only to the Auxiliary, but also to the State Medical Society.

"From the earliest date, the doctor's wife quiet, patient and willing to help, has stood at his elbow, almost unnoticed. Then came the time when she gently made her presence known—she was eager to help him. A few years ago, she nudged his elbow, informing him that she was ready to help him. He accepted the challenge, and so the Woman's Auxiliary to the Medical profession came into life, for in 1917 the Woman's Auxiliary to the Dallas County Medical Society was formed, and in 1922 in St Louis the Woman's Auxiliary to the American Medical Association was launched by Mrs Samuel Clark Red of Houston, Texas.

"The Woman's Auxiliary to the Medical Society of the State of New York, organized March 1936, stands at the elbow of the State Medical Society—willing and ready to serve."

News of Activities

The executive board held a meeting on September 29 in Bayport, L I, with Presi-

The Physicians' Home, Inc.

The Annual Meeting of the Physicians' Home, Inc., was held on October 19, at which meeting it was decided to extend the services of the Physicians' Home by accepting and caring for additional guests. In order to facilitate this policy it will be necessary for the Home to make arrangements for taking care of their guests in various portions of the State of New York. The Directors are anxious to make contacts with individuals of good character—preferably the widows of doctors who, having homes to maintain, would be agreeable to take as house guests one or more of our aged physicians. The Physicians' Home, Inc., are prepared to pay such individuals a reasonable amount weekly for the maintenance of their guests. If any of the members of the Medical Society of the State of New York know such householders who are desirous of entering into such an agreement with the physicians' Home we would be very grateful to have their names for our consideration.

CHARLES GORDON HEYD, M.D.,
President

B. WALLACE HAMILTON, M.D.
Treasurer

NASSAU COUNTY A brief business session was held on October 19 at the Garden City Hotel and then the meeting adjourned to allow members and guests to visit the exhibit and demonstrations of an elaborate collection of educational material, prepared and supplied by the New York State Institute for the study of Malignant Diseases at Buffalo, the Memorial Hospital of New York City, the Tumor Service of Meadowbrook Hospital, the American Medical Association, the American Society for the Control of Cancer, and several local doctors. The speaker was Dr. Louis C. Kress, assistant director of the State Institute for the Study of Malignant Diseases.

QUEENS COUNTY On November 6, the County Auxiliary held its annual fall dinner dance at the Hotel Pennsylvania in New York City.

COMMITTEE ON LEGISLATION OF THE STATE AUXILIARY The chairman, Mrs. Henrietta Stewart Kiee of Garden City, sent in the following announcement:

Auxiliary members and doctors' wives everywhere, find themselves either interested spectators or bewildered participants in this chameleonic era of world activities.

There is a constant appeal and challenge for our intelligent thought not completely usurped by our daily routine of planning meals and tending the phone.

There is the urge to stand shoulder to shoulder and participate in events. Fifty years ago these events were not foreseen. Outside

interest would have been unnecessary and unethical.

But time marches on. Today the legislative committee of the Woman's Auxiliary to the Medical Society of the State of New York, though still a diminutive, young offspring, gives promise nevertheless of being a helpful and vigorous one.

Its steady growth, the ability to fulfill any hopes at its inception will be in direct proportion to the education, guidance, understanding, and cooperation given.

The program of this committee's activities will be suggested by the medical advisors to the Auxiliary, as well as the legislative committee of the Medical Society.

We can make no laws and we act only when requested by the legislative committee. Any apprehensions as to our conduct thereby are stilled.

Untold possibilities of this committee's accomplishments are envisioned with the endless and abundant opportunities at our command. The manner and degree of such achievement will depend upon the interest and study.

It is obvious that if we are to become useful, well-informed auxiliary members, education must be a vital factor.

As we approach this oncoming legislative year, let us be alert to such measures which affect the public health and the medical profession.

Careful consideration of such topics in our county groups, will make this legislative-educational project, a major one. Let us appreciate that this committee's interests are definitely our personal one.

Let us be prepared to stand by or assist in a manner befitting and worthy of our association with the oldest of all professions.

PNEUMONIA CONTROL PROGRAM

Some misunderstanding has occurred regarding the Pneumonia Institutes which are being sponsored by the State Department of Health and the State Medical Society, especially regarding the one to be given in New York City on November 23. These Institutes are for physicians of the State, except those residing in New York City. This exception is due to the fact that the Institutes are financed by the State Department of Health, which has no jurisdiction over the health work in New York City.

Despite the fact that the notices regarding these Institutes published in this JOURNAL and other places, indicated this fact, fifty-five applications have been received from New York City. This matter has

been discussed with the Commissioner of Health of New York City and Dr. Peter Irving of the Advisory Committee on Pneumonia Control of New York City, who have been urged to provide a similar Institute for physicians in New York City.

The Council Committee on Medical Education has been advised that such an Institute will be arranged as early as possible. Consequently all applications which this Committee has received from New York physicians will be turned over to the Commissioner of Health of New York City, who has agreed to consider them as applications for the local Institute, and will give them priority over applications to be received.

MEDICAL NEWS

Number 221

four clergymen of Buffalo and vicinity asking them to comment on the practice of vivisection brought only five replies from the physicians and three from the clergymen, Mrs Alice K Millard, president of the Erie County Anti-Vivisection society, announced on Oct 19

THE CLINICAL AFTERNOON and dinner of the Buffalo Academy of Medicine will be held on November 17, at Hotel Statler, Buffalo, in the Terrace Room at 2 30 P M. The program "The Diagnosis of Lesions of the Stomach by GastroscoPy" Rudolf Schindler, M D, Associate Professor of Medicine, School of Medicine University of Chicago "Drugs in the Treatment of Diseases of the Heart." Robert Louis Levy, M D, Professor of Clinical Medicine, College of Physicians and Surgeons Columbia University, New York City "Responsibility of the Profession" Irvin Abell, M D, President-elect of the American Medical Association, Clinical Professor of Surgery School of Medicine, University of Louisville. "Diagnosis and Management of Surgical Diseases of the Colon and Rectum," Richard Bartley Cattell, M D, The Lahey Clinic, Boston, Mass

At the dinner, the speaker will be Morris Fishbein, M D, Editor of the *Journal of the American Medical Association*, and his topic, "Social Security and the Physician"

Genesee County

DR. LEROY V GARDNER and Dr Homer L Samson spoke on "Pneumoconiosis," before the Genesee County Medical Society on October 28 at the Batavia Club

Jefferson County

THE MEDICAL SOCIETY of Jefferson county was entertained by Dr Sutherland E Simpson, superintendent of the Jefferson county sanatorium, at the society's meeting on Oct. 14, at the sanatorium. Dr Jesse R Pawling, president of the society, presided. The guest speaker was Dr William Warner Woodruff, consulting surgeon to the Trudeau sanatorium whose topic was "Surgery of the Chest"

Kings County

DURING NOVEMBER, the radio program of the Medical Society of the County of Kings is devoted to the prevention and study of tuberculosis. This program is under the joint auspices of the Medical Society of the County of Kings and Academy of Medicine of Brooklyn and the Brooklyn Tuberculosis and Health Association

THE FIRST REGULAR MEETING of the Woman's Auxiliary to the Medical Society of the County of Kings, Mrs Edwin A Griffin, president, was held on Oct 19 at the Kings County Medical Society Building. Dr Samuel Frant was the guest speaker

THE RIDGEBORO MEDICAL SOCIETY met on Oct 21 at the Kings County Lighting Company. It was addressed by Dr Howard Lillienthal on the subject, "Intro-Thoracic Suppuration." Dr Ralph Harlowe of the Long Island College Hospital discussed the paper. Dr Clifton Bogardus presided

Drs G H DAVIS and O C PERKINS finished "one-two" on Oct 5 in the annual golf tournament of the Associated Physicians of Long Island at the Queens Valley Golf Club. Dr Davis had 80, Dr Perkins 81

Monroe County

MODERN TREATMENT of pneumonia was discussed at the Monroe County Medical Society meeting on Oct 19 at the Rochester Academy of Medicine

Dr Jesse G M Bullock, clinical professor of medicine at New York University College of Medicine and visiting physician to Harlem Hospital and Willard Park Hospital, spoke on "The Management of Pneumonias"

Discussion was led by Dr Edward S Rogers of the bureau of pneumonia control of the State Department of Health. Dr. William S McCann of the University of Rochester School of Medicine, and Dr Edward G Whipple, society president

A dinner conference for chiefs of the medical staffs of Rochester hospitals was held at the University Club preceding the meeting. An all-day institute was held at Strong Memorial Hospital under sponsorship of the state medical society

A NEW ATTACK ON TUBERCULOSIS was launched in October by the Tuberculosis and Health Association and the Monroe County Medical Society with the announcement of the opening of a "Healthy House"

"Healthy House" is at 285 Alexander St, Rochester in a building lent by John Pike. It is equipped for a display of motion pictures prepared under direction of the State Department of Health. Rochester Council of Social Agencies and Public Health Nursing Association

Although paraphernalia and programs are designed primarily for instruction of health workers in the technic of health education, the public are invited to see the pictures and hear the instruction

Medical News

Albany County

DR EDWARD M. BELL, Colhoun health commissioner who died on Oct. 19, had practiced medicine there more than forty years.

Broome County

DR ROBERT A. KILDUFFE, director of laboratories of the Atlantic City hospital spoke on "The Clinical Utilization of Blood Studies" at a meeting of the Binghamton Academy of Medicine on Oct. 19.

Columbia County

THE FIRST MEETING of the season of the Woman's Auxiliary to the Columbia County Medical Society, Mrs. Henry C. Galster, president, was held on Oct. 19, in Cavell House, the Nurses' Home, on Prospect avenue, Hudson.

The speaker of the afternoon was Miss Edith Laey, director of nursing, of the School of Nursing of the Hudson City Hospital.

Dutchess County

DR GORDON MACKENZIE, Millbrook Golf and Tennis club links' star, and Dr. M. B. Bevier of the Dutchess Golf and Country club captured major laurels in the Vassar hospital handicap, held at the South road links on Oct. 6. Others who captured awards included Dr. John Turiga of Southern Dutchess, Dr. John F. Rogers, Dr. Gilbert MacKenzie of the Millbrook club, Dr. V. F. Downing, also of Millbrook and Dr. Charles Kovacs and Dr. Joseph Cummings.

Erie County

DR EDWARD E. HALEY, chairman of the Health board of Buffalo was appointed deputy health commissioner and director of the Health Department's Communicable Disease division at an annual salary of \$6000, on Oct. 15.

Dr. Haley said he will continue temporarily at least as Health board chairman although he will decline the \$1000 annual salary.

Dr. Haley intimated he plans reorganization of the operation of the communicable disease division.

"The division is all mixed up and is doing some types of work that it is not

called upon to carry out," he said. "I plan to bring right out of chaos."

WITH FOUR PROMINENT medical men as speakers, a public meeting on the control and prevention of cancer was held Oct. 28 in YMCA building, Buffalo, under the joint auspices of the Academy of Medicine, the Medical Society of the County of Erie, the Eighth District Dental society and the health division of the Council of Social Agencies. Dr. John T. Donovan presided.

Speakers and their subjects were: Dr. C. C. Little, managing director of the American Society for the Control of Cancer, "The Campaign Against Cancer"; Dr. Burton T. Simpson, director of the State Institute for the Study of Malignant Disease, "Scientific Facts About Cancer for Doctor and Layman"; Dr. John W. Swan, executive secretary of the New York State committee of the American Society for the Control of Cancer Inc., "What the Layman Should Know," and Dr. Karl F. Eschelman, chief of cancer service of the Buffalo City hospital, "Diagnosis and Treatment for Cancer in a Public General Hospital."

A NEW PROPOSAL for compensating physicians of Buffalo for treating patients on the welfare rolls is under consideration by members of the Medical Society of the County of Erie.

Outlined at the society's first Fall meeting on Oct. 18 in Hotel Statler by Dr. Joseph C. O'Gorman, chairman of the economics committee, the plan calls for an allotment of funds to the society by the city on the basis of so much a month for each family or each member of a family on the relief roster.

The agreed monthly budget less cost of administration would be allocated to co-operating physicians on the basis of service rendered. Dr. O'Gorman explained. All details of administration would be directed by the society. The plan would apply only to medical care in the home and would not replace existing hospital or clinic facilities, Dr. O'Gorman said.

After prolonged discussion action on the plan was deferred until the society's meeting Nov. 15.

Dr. John T. Donovan, president of the society, presided.

LETTERS to 167 physicians and sixty-

Oneida County

THE ONEIDA COUNTY MEDICAL Society has appointed a committee to confer with the Utica Academy of Medicine on securing a full-time paid secretary

OPPOSITION TO ESTABLISHMENT of a new county Medical laboratory is voiced by the Medical Society of Oneida County in a letter to the Board of Supervisors

The communication declares members of the society are opposed to such a project "because they feel that there are enough laboratories in the county at present to take care of all necessary work."

Action of the society was unanimous, according to the letter, which said "it was also suggested that it be pointed out to the various towns that they can arrange to have their work done at the state laboratory the same as does Utica and New Hartford"

Ontario County

DR. FREDERICK C CLELLAN, Canandaigua city health officer, was elected president of the Ontario County Medical Society on Oct 12 at the 132nd annual meeting at East Lake shore. At the same time, Dr Daniel A Eiseline was named secretary and treasurer for the forty-first consecutive year, and Dr A W Armstrong was elected vice president, succeeding the new president

Approximately 60 members and guests attended the session, which opened with a business meeting, followed by dinner and a program, with Dr Ernest L Stebbins, district state health officer, as speaker. Dr Stebbins discussed "Source, Diagnosis, Clinical Course, and Treatment of Some of the More Frequent Streptococcus Infections Encountered in Medicine"

Dr Chauncey W Grove retiring president, presided. Named to the Board of Censors for another year were Drs J S Morabito, Malcolm R Blakeslee, and A G Odell. Dr W S Thomas was reelected editor of *The Bulletin*, quarterly publication of the society. Dr H J Knickerbocker will be delegate, with Dr M D Dickinson alternate to the state convention next Spring. The next meeting will be in Canandaigua Jan 11

DR. A W ARMSTRONG was host at the meeting of the Canandaigua Medical Society, on Oct. 14, when Dr Adrian Taylor of Clifton Springs spoke on "Empyema"

Oswego County

THE 116TH ANNIVERSARY of the Medical society of Oswego county was observed with a dinner meeting Oct. 14. The speakers

were Charles H Goodrich, M D, F.A.C.S., president of the Medical Society of the State of New York, whose subject was "Preventative Medicine" and Morris Fishbein, M D, editor of the *Journal* of the American Medical Association, who spoke on "Medicine and the National Policies"

Queens County

THE PROGRAM OF THE Medical Society of the County of Queens on Oct. 26 included papers on "Therapeutics of Menstrual Dysfunction," by Raphael Kurzrok, M D, and "Breech Delivery—The Simple Application of Forceps in Occiput Posterior," by Hervey Clock Williamson, M D

The program also included nominations for offices to be filled at the Annual Meeting on November 30. *President-Elect*, Drs Joseph Wrana and Jacob Werne, *Secretary*, Dr Frank R Mazzola, *Assistant Secretary*, Dr Chester L Davidson, *Treasurer*, Drs William T Berry and Tobias Watson, *Assistant Treasurer* Dr Daniel J Swan, *Historian*, Dr Carl Boettiger, *Directing Librarian*, Dr Carl Boettiger, *Assistant Directing Librarian* Dr William Benenson, *Five Censors* Drs Edward Steiner Raymond Murphy, John Wolfram Walter Kerby, Jacob Werne, Robert Yanover, *Five Trustees*, Drs William T Berry, Francis Riley, Albert Voltz, Walter Lynn, Herbert Langer, Thomas d'Angelo, *Delegates*, Drs James M Dobbins, H P Mencken, James R Reuling, *Alternates*, Drs Walter Lynn, Daniel Swan, Charles Miller

THE ANNUAL MEETING of the section on pediatrics is scheduled for December 9, at 8 30 P M, at the Society's Building. The program will be "Dermatological Conditions in Children." Members of the Society are invited to attend

THE WOMAN'S AUXILIARY to the Medical Society of the County of Queens held its annual fall dinner-dance November 6

Rensselaer County

DR. AUGUSTUS J HAMBROOK was named a member of the state advisory council on health and physical education in public schools by the Board of Regents on Oct 15. He will succeed Dr Floyd S Winslow

Rockland County

BOOKS

[Volume 37]

Disease following such injuries must appear within one week or ten days.

Latent and symptomless pathological conditions are often suddenly activated by trauma and controversy often arises as to whether a disease appearing after an injury is compensable.

Coronary occlusion following blows to the chest in patients with coronary disease, peripheral vascular lesions, the disputed question of brain tumors following head injuries, foetal deaths in pregnant women, spontaneous fractures, conditions in the genito-urinary and gastro-intestinal tracts and mental derangements are thoroughly described. With the necessary number of physicians doing industrial medicine and compensation work, this book offers important information and should be read by all as all specialists are considered.

MAURICE J DATTELBAUM

Diseases of the Nose, Throat and Ear
A Handbook for Students and Practitioners
By I Simson Hall, M B Duodecimo of
423 pages, illustrated Baltimore, William
Wood & Company, 1937 Cloth, \$4.00

Diseases of the Nose, Throat and Ear
by Hall is a handy small volume enumerating most of the more common abnormal and diseased conditions of these areas and discussing management and treatment which could be carried out by some general practitioners. It is a book which might also be used by students. However, there are many books of this scope and these needs have long been met. Furthermore, there are many instances in which too much knowledge or ability in the general practitioner seems to be taken for granted, and surgical treatment is outlined quite casually, which should never be undertaken except in expert hands.

CHARLES R WEETH

Clinical Allergy By Louis Tuft, M D
Octavo of 711 pages, illustrated Philadelphia, W B Saunders Company, 1937 Cloth \$8.00

The doctor states in his preface that there is a distinct need of a book on allergy which meets the needs of the general practitioner, the medical student, and the beginner in the field. In this the reviewer is in complete accord. Some of the recent books on allergy are so full of controversial matter that only confusion can result from their perusal by any one other than an allergist. The present volume presents in a direct way what we really know about allergy. Its chapters cover anaphylaxis in animals and in man and its relation to allergy, methods of diagnosis, history taking which is very important, as it is in every field of medicine, skin testing, and the methods and principles of treatment.

All of the important manifestations of

allergy are covered as to etiology, pathology, symptomatology, diagnosis and treatment. Allergy as related to the specialties is also covered, namely, dermatosis, allergy in children, neurology, ophthalmology, and otorhinolaryngology. The appendix contains material on laboratory methods, directions for patients, lists of allergens and their sources, allergic diets and recipes. The book reads easily and is full of meat. The reviewer recommends it highly to the doctor wishing to keep abreast in this new and growing field of medicine.

GEORGE A MERRILL

The Technic of Local Anesthesia By
Arthur E Hertzler, M D Sixth edition.
Quarto of 284 pages, illustrated St Louis,
C V Mosby Company, 1937 Cloth, \$5.00

This latest edition of local anesthesia by Hertzler gives a clear description of the author's successful technique in the management of his surgical work. The first portion of the book is quite similar to the material in earlier editions. In the later chapters the author has gone more extensively than before into the subjects of paravertebral anesthesia and sacral block, and is very moderate in his claims for them. A chapter on spinal anesthesia, written by one of his associates gives a middle-of-the-road opinion of the usefulness of the method and a chapter on intravenous anesthesia closes the book. Yet with the multitude of new drugs introduced to the medical profession for intravenous anesthesia even this 1937 edition fails to mention some of the latest and most advertised preparations.

GEORGE W TONG

Pediatric Dietetics By N Thomas Saxl
M D Octavo of 565 pages, illustrated Philadelphia, Lea & Febiger, 1937 Cloth, \$7.00

In outlining a diet for infants and children, it is imperative that one be conversant not only with the rules and foundation of food stuffs for the human being but also it is necessary to be able to give in detail how to prepare and select a proper dietary. If one merely outlines a 24 hour diet it is not enough. How often does the mother reach home only to call up again and again wanting specific instructions, as to how much vegetable or meat or cereal her child should be served, also, desiring a list of food stuffs that happen to be in season.

This book more than fulfills what most of our modern textbooks leave out. The dietetic handling of various diseases and the reasons for it is timely. The bibliography leaves nothing undone. The bibliographer can well recommend this book for anyone's office.

THURMAN B GIVAN

occurred in individuals in the third decade of life (Table II). The group consisted of fifty-three male, white adults and one female, white adult. The period of exposure varied from two weeks to three months. The onset of acute symptoms in forty-three (79.6%) of this group followed absorption through the respiratory tract. The period of exposure was somewhat longer and symptomatology not so severe in those patients (20.4%) in whom it was believed that the gastrointestinal tract was the probable portal of entry.

The inhalation of lead was responsible for the onset of acute symptoms in forty-three patients. There were eleven painters who developed acute toxic symptoms. In seven, symptoms appeared following the inhalation of lead dust (Table III).

During 1935, a group of thirty-five riveters were employed in the construction of a bridge. The steel girders used were painted with red lead and in driving the hot rivets through the girders, the paint was melted and fumes escaped. These men had worked approximately ten to fifteen years as riveters. Their work was usually done out of doors, consequently the concentration of lead in the air never reached sufficiently high proportions to constitute a hazard, but in the construction of the tower of a bridge a situation comparable to an enclosed chamber was created. As no precautions were taken to ventilate the chamber and masks were not worn, two weeks after beginning the job several of the workers were seized with acute abdominal colic and complained of constipation.

Gastrointestinal tract. Symptoms referable to the gastrointestinal tract occurred frequently. Acute abdominal colic was the most striking clinical feature. Epigastric pain, constipation, and colic occurred in eighty per cent of this group. All these men continued to work despite weakness and loss of weight until the onset of severe colic. In many, the acute episode was heralded by the onset of violent lower abdominal pain. Nausea and vomiting were present in twenty-four per cent of the group. The loss of weight was probably due in a large measure to the loss of appetite. The men feared to eat because "they would have pain." The average loss of weight was approximately eighteen pounds. The "general weak-

ness" (52%) was probably due to insufficient food intake.

Neuromuscular system. Under this heading we have grouped all complaints referable to the joints, nerves, muscles, and brain. Wright²³ and Linenthal²⁴ called attention to the "rheumatic pains" which occur in lead workers. Myalgia due to lead not infrequently remains undiagnosed in the absence of a history of occupational exposure. Two patients complained of severe pain in the mid and lower back. If a history of occupational exposure had not been obtained, lumbago of undetermined etiology would have been the diagnosis. Eighteen (33.3%) complained of pain referable to the muscular system and twenty (37%) had joint pains. The elbows, wrists and ankles were the joints of predilection. The joints were not swollen, disfigured or discolored and there was no interference with joint function. Tenderness was not present. The pain was placed "in the joint" and was fleeting in character. In the absence of a history of occupational exposure a diagnosis of arthralgia of rheumatic or nonspecific origin would have been made. Numbness in the extremities was noted in ten (18.5%) of our patients and sleeplessness in eight (14.8%). In most instances pain in the abdomen and in the joints was more pronounced at night than during the day. These patients were tired but sleep was disturbed because of the increased severity of the pains. Headache was present in seven (12.9%). These headaches were not localized and in only one instance was it sufficiently severe to indicate spinal puncture. Spinal fluid findings were normal in every respect including manometric pressure, cytology, albumin, globulin, and sugar. Serological study of the fluid withdrawn was negative for syphilis. One patient developed auditory nerve deafness due to the toxic effect of lead.

Physical examination. The paucity of positive findings on physical examination was striking. Pallor was noted in forty (76.5%) and a lead line in eleven (20.3%). Oral hygiene is an important factor in the production of the lead line. When the oral hygiene is good a lead line is seldom seen even when the diagnosis of acute lead poisoning is estab-

tenderness, muscle spasm, fever, rapid pulse, leukocytosis, and polynucleosis. The diagnosis of chronic lead poisoning is best portrayed by the changes in the nervous system. In instances of atypical and bizarre neurological signs and symptoms, lead as a causative factor should be considered. Altman and Nowotny¹⁷ described four cases of atypical nonindustrial lead poisoning occurring in adults. These cases of lead poisoning were complicated by a primary spinoperipheral neurologic disorder. All four patients came from the same district and upon investigation, lead in the drinking water was found to be the responsible agent. Lead as a possible etiologic factor in multiple sclerosis was described by Cone and his associates.¹⁸

The respiratory tract is probably the most important portal of entry through which lead dust and fumes gain entrance into the circulation and produce symptoms of intoxication. Absorption of lead through the normal skin almost never occurs. The normal skin is practically impermeable to the inorganic compounds

of lead. Even if the skin is damaged by inflammation, infection or injury, it is doubtful if absorption ever takes place via this route. Among the organic compounds of lead, tetraethyl lead has been shown,^{19, 21} by virtue of its solubility in alcohol and miscibility in oils and fats to be absorbed through the unbroken skin in sufficient amounts to constitute a hazard. We call special attention to the lead content in tetraethyl gasoline because of the increasing popularity of this gasoline. Professor Martin Meyer²² of the Department of Chemistry of the Brooklyn College, in a study of the exhaust of various automobiles found that 22 to 150 mgm of lead were discharged per minute. It becomes evident that the exhaust from aeroplanes and automobiles constitutes an ever increasing lead hazard to the nonindustrial population of any large city.

Lead Poisoning In Industry

During the four year period of 1932-5* (Table I) there was a total of 342 cases of lead poisoning with an average disability of seventy-three weeks. In the group with permanent partial disability there were eight cases (2.3%) and in the group with death and permanent total disability there were twelve cases (3.4%). During the same period of time 322 (93%) were temporarily disabled with an average of 27.5 weeks. Considering the number of employees engaged in the various lead industries in the State of New York, the number here reported may be considered comparatively small. However, with the advances made in the field of preventive medicine, especially in the field of lead poisoning, many of these cases, if not all, could possibly have been avoided.

Acute Lead Poisoning In Industry

We are basing this report on a study of fifty-four cases, the majority of which

*We had the opportunity of reviewing the records of the New York State Department of Labor on the subject of industrial lead poisoning through the courtesy of Dr. Eugene B. Patton and Dr. Leonard Greenberg (Director of the Division of Statistics and Director of the Division of Industrial Hygiene, respectively, of the Department of Labor, State of New York).

vascular system is not adversely affected in acute lead intoxication

Chronic Lead Absorption With Acute Toxic Symptoms

We have chosen this title rather than chronic lead poisoning by reason of the fact that this group of thirty-eight male, white adults had been exposed to the absorption of lead for many years and suddenly developed acute toxic symptoms primarily referable to the gastrointestinal tract.

The majority of these cases occurred in individuals in the fourth and fifth decades of life. The period of exposure varied from two to thirty-three years (Table IV)

Absorption of lead from the gastrointestinal tract in twenty-four painters (63.1%) over a period of twenty to thirty years was followed by an acute toxic episode after exposure to the inhalation of lead dust for a short period of time. In a few instances acute colic followed without any undue exposure to the inhalation of lead dust and during the routine and usual work. The occupational distribution of the other remaining fourteen cases is such that the chronic absorption of lead was due to inhalation (Table V)

Gastrointestinal. Symptoms referable to the gastrointestinal tract were almost as prominent in this group as was noted in the group with acute lead poisoning. Colic and constipation were the most striking clinical features. Colic occurred in twenty (52.6%) of the patients. It presented all of the characteristics and differed in no way from that noted in the acute group. Constipation was the next most frequent complaint and was noted in seventeen (44.7%). Nausea, loss of appetite, loss of weight, and abdominal pains were each recorded in ten (26.3%). Loss of weight was not quite as marked nor did it occur as rapidly as in those who suffered from acute lead poisoning. It was the fear of pain that resulted from the intake of food which caused them to abstain from eating. The resulting weakness was probably due to malnutrition.

One of the patients developed diarrhea which was accompanied by a high temperature, rapid pulse, and subsequent

jaundice. The blood study indicated a leukocytosis and the sedimentation rate was rapid. Culture of the stool yielded a nonhemolytic streptococcus. This case was unusual in that infection probably liberated lead from the tissue depots where it had been stored innocuously.

Neuromuscular system. The diagnosis of chronic lead poisoning is frequently made following the onset of changes in the nervous system. It is therefore to be expected that in a group of workers in whom absorption occurred at a slow rate and over a long period of time that neurological manifestations would occur more frequently than in those who had been exposed for a short period of time. Myalgias were present in thirteen (34.1%). The pains were severe and were located in both upper and lower extremities. The large muscle groups were affected. There was no disturbance of motion in any of the joints. Headache occurred in eight (21.1%). It was not severe and could not be localized and varied from a "tightness across the temples" to a "pulsating pain" which lasted for short periods of time. There was no indication for spinal puncture. General decrease of muscle power, weakness of grip, numbness of the arms and shoulders, dizziness, and disturbances of vision were present in six (15.9%).

Physical examination. Unless signs were evident the absence of positive find-

lished. The decay of vegetable matter in the mouth causes the liberation of hydrogen sulphide which combines with lead in chemical composition to form a black lead sulphide. Much stress has been placed on the presence of the blue line on the gum. When present it is of value only in so far as it lends confirmation of lead absorption. Mercury and bismuth produce a discoloration of the gums which cannot be distinguished from the lead line. Severe primary anemia and blood dyscrasias may similarly discolor the gingival margin. In a group of workers exposed to the absorption of lead, the presence of the lead line in a few may perhaps be used as an index of lead absorption in the group. The rate of absorption, the concentration of the lead inhaled, and the severity of symptoms produced cannot be estimated from either the presence or absence of the lead line. In spite of poor oral hygiene in seventy per cent of our patients, a lead line was noted in only eleven (20.3%). Examination of the heart and lungs showed no abnormalities. On abdominal examination cecal tenderness was present in eight (14.8%) and sigmoid spasm in twenty-five (46.2%) of the group. Manual pressure over the site of the abdominal colic invariably relieved the pain. In one patient a carcinoma of the rectum was found.²⁶ Despite the high concentration of lead in the tissues the carcinoma grew rapidly. The neurological examination revealed no abnormal findings except that occasionally slight decrease in vibratory sensations of the hands and fingers was noted.

Laboratory data. The hemoglobin was slightly decreased. The total red blood cell count indicated a moderate anemia in keeping with the reduction of the hemoglobin yet not as low as one would estimate from the severity of the pallor. A constant finding was the diminution of the platelet count to below 200,000. In spite of the reduction of the platelets, bleeding and coagulation time was normal. On differential study a lymphocytosis was the rule. Basophilic stippling was noted in forty per cent of our patients. As early as 1902, Keil²⁸ noted that, "the red blood cells in patients suffering from severe anemia due to carcinoma gave the appearance of basophilic granules. The salts of copper, cobalt, arsenic and thal-

lium produced a similar effect on the cytoplasm of the red blood cells. Certain gasses such as carbon monoxide and blood diseases such as pernicious anemia, Hodgkins disease, anemia caused by blood parasites and sepsis produce changes in the cytoplasm of the red blood cell which are indistinguishable from the stippling noted in lead poisoning." Chronic anilin poisoning²⁷ affects the red blood cell and makes its cytoplasm indistinguishable from that noted in lead poisoning.

Examinations of the urine, stool, and whole blood for lead were done as a routine on all patients on admission and during the period of treatment at the hospital. In forty-one patients (75.9%), lead was present in abnormal amounts in the urine on admission examination. Abnormal amounts of lead were present in the stool in thirty-two (59.2%). Only twenty-one (38.8%) had abnormal amounts of lead on examination of the whole blood. Chemical examination of the blood revealed normal values of sugar, urea, creatinin, uric acid, and CO₂ combining power. Calcium and phosphorous studies on whole blood also gave normal values. Examinations were done to determine the function of the liver and kidneys, stomach, and cardiovascular system. In a future communication, results of these examinations will be presented in detail. The usual tests were employed for study of renal and hepatic function. In none of the patients were we able to find convincing evidence of impaired function as indicated by the examinations done. Fluoroscopic examination of the gastrointestinal tract showed varying degrees of spasm of the colon, especially affecting the distal half. Retention of barium for longer than seventy-two hours was the rule. Approximately fifteen per cent of this group had marked spasticity of the descending colon and sigmoid with retention of the barium for longer than 120 hours. In one patient suspicious evidence of an ulcer of the duodenal bulb was noted. In almost all of our patients hypotension was present. In addition to the physical examination of the cardiovascular system, fluoroscopic examination of the heart, electrocardiographic studies, oscillographic studies, and the cold pressor test as described by Brown²⁸ were done. Our experience indicates that the cardio-

Even after admission to the hospital and during the period of "control" study these blood pressure determinations remained as noted. Within forty-eight hours after the institution of deleading therapy a decided and prompt drop in both the systolic and diastolic blood pressures occurred. Blood pressure determinations then read 120/70, 160/90, and 140/78 respectively in the order mentioned. We call attention to the paroxysmal hypertension.

Cardiac hypertrophy was noted fluoroscopically and confirmed roentgenographically in ten (26.3%). Hypertensive cardiovascular disease was responsible for the cardiac hypertrophy in eight, in the remaining two, one was due to syphilis and the other was an idiopathic cardiac hypertrophy. Electrocardiographic studies were done on all thirty-eight patients. Twenty-eight of these tracings showed no deviation from normal. The abnormalities were distributed as follows: left axis deviation four, auricular fibrillation one, and myocardial damage five. Abnormalities in the R-T transmission and T wave were the only findings indicative of myocardial damage. Oscillometric determinations were done on the dorsalis pedis, posterior tibial, and the popliteal arteries of both lower extremities. None of the curves showed evidence of occlusive vascular disease. Cold pressor tests were performed on eight patients. In only one instance was an abnormal response observed. The basal blood pressure was

106/74. After the hand was immersed in water at four degrees C, the blood pressure rose to 150/106. This patient gave a maternal history of hypertensive vascular disease. The patient himself was a forty year old white male probably belonging to the essential hypertensive group. A detailed discussion of the many interesting phenomena observed in the study of the cardiovascular system in this group with chronic lead absorption will be presented in another communication.

Summary

1 The absorption of lead in the general civilian population and its possible relation to disease requires further investigation and study. The diagnosis of lead poisoning in nonindustrial life is most frequently among children.

2 The occurrence of lead poisoning in the State of New York for a period of four years has been reported. It is probable that the disability and cost of illness could have been reduced to a minimum if the advances made in the field of preventive medicine were practiced with greater care.

3 We have reported fifty-four cases of acute lead poisoning and thirty-eight cases of chronic lead absorption with acute toxic symptoms and have analyzed the data presented.

ings on physical was striking. A moderate degree of pallor was noted in six (15.7%). The lead line on the gum was noted in eight (21.1%) and was absent in thirty (78.9%). Elevation of blood pressure was noted in eight (21.1%). All these patients were between the ages of forty-five to sixty years. Cardiac hypertrophy was found in ten (26.3%). Varying degrees of abdominal tenderness with spasm of the sigmoid and lower third of the abdomen was noted in seven (18.1%). General decrease of muscle power occurred in six (15.7%) and atrophy of the interosseal muscles in three (7.8%). Bilateral wrist drop was present in two patients. Finger drop was also noted in two patients.

In analyzing the causes of disturbed vision in six of our patients, retrobulbar neuritis of the optic nerve, Argyll-Robertson pupil as part of a central nervous system syphilis, and arteriosclerosis of the retinal artery were each present twice. The retrobulbar neuritis of the optic nerve was the only cause of disturbance of vision which could reasonably be attributed to lead. Sclerosis of the retinal artery was part of a generalized arteriosclerotic process in two patients both of whom were in the fifth decade of life.

Laboratory data. Slight decrease in the hemoglobin was paralleled by a decrease in the red blood cell count. Stippling was found in the blood smears of six (15.7%). Chemical examination of the urine, stool, and whole blood was done routinely on admission and following the institution of deleading therapy. Twenty-four hour specimens of both urine and stool were collected for examination. Proper precautions were exercised in the selection of containers and in the method of collection. Cleanliness of the apparatus was rigidly guarded. The importance of meticulous care in the estimation of lead in biological materials was recently stressed by Gettler.²⁰ The Dithizone method for the detection of lead was carried out by qualified chemists. Examination of the admission specimen revealed the fact that abnormal amounts of lead were excreted in the urine of thirteen patients (34.1%) and in the stool of eight (21.1%). Abnormal amounts of lead in the whole blood were found in only five (13.1%). Chemi-

cal examination of the blood of thirty-seven in this group revealed normal values for sugar, urea, uric acid, creatinin, and CO₂ combining power. Calcium and phosphorus studies on the whole blood remained fairly constant and within normal limits in all. It is interesting to note that one patient who had a marked nitrogen retention also had evidence of severe renal damage associated with arteriosclerotic and hypertensive cardiovascular disease. This patient had been exposed to the absorption of lead for twenty-five years prior to the onset of abdominal symptoms. He recalled having been "sick several times" during childhood but the exact nature of these illnesses were not known to him. He had never been examined by a physician since childhood. Whether or not lead was responsible for the marked hypertension associated with hypertrophy of the left ventricle, advanced arteriosclerosis, and contracted kidney (autopsy finding) or whether the renal disease was primary and the hypertensive and arteriosclerotic heart disease was secondary remains a matter of conjecture.

Cardiovascular system. Studies of the cardiovascular system were done as a matter of routine on all patients in this group. The studies included blood pressure estimations, fluoroscopic examination, teleroentgenographic studies, oscilometry, cold pressor test, and electrocardiographic studies. Hypertension was noted in eight (21.1%). It is of interest to note without going into detail a phenomena which was observed in three patients of the hypertensive group. In each instance blood pressure determinations were made repeatedly to eliminate the extrinsic factors which might be responsible for the elevation of blood pressure. The final constant reading obtained was 190/110, 198/104, and 162/90 respectively. These patients had been removed from the occupational hazard for several weeks before they came under our observation. Deleading therapy was instituted as a hospital procedure to insure absolute control of the patient, rigid adherence to the diet, and to facilitate the collection of urine, stool, and blood for study as indicated. Our patients were not confined to bed during the hospital stay which varied from two to three weeks.

Several have had complicating interdigital patches. Never has it been observed on the palm.

On the bulb of the big toe it may bear a superficial resemblance to a nevus. But the patch is more frequently mistaken for a common callus or localized hyperkeratosis, or for a subacute scaling dermatophytosis. Paring shows its true nature, with the tell-tale capillary bleeding points. Many patients have had mosaic patches for years, considering them simple calluses.

Our findings are not in accord with Andrew's statement that the cores "are surrounded by a firm horny ring." Rather has it been our observation that the individual warty segments in a patch are not round, nor are they encircled by a marked horny membrane.

Apart from the multiplicity of coalesced wart-cells we have found that the character of the border of a patch is important in diagnosis. Even a large compound verruca vulgaris on the sole has a sharply limited border, in fact many of them can be encircled by a shallow spoon-curet and enucleated. Mosaic patches, on the other hand, have a diffuse border, with small warts making the edge irregular. There have been borderline cases that for a time have puzzled us.

But in general, we have found that those with sharp limitations proved to

be radiosensitive and should not be included in the mosaic category.

One point which has impressed us is the frequent association of the mosaic wart with dermatophytosis, a matter of coincidence perhaps, on account of the ubiquity of the latter. Still we almost always find the two diseases coexistent. This does not obtain nearly so often in the case of the common plantar wart. In this connection several patients have stated that their patches arose on sites previously involved by eczematoid ringworm.

The mosaic wart rarely appears in clinic practice. All but two of our cases have been private. On this account our opportunity for obtaining material for microscopic study has been limited. Private patients, to whom we could extend no hope of cure by excision, were unwilling to have an open wound on a weight-bearing surface, undercutting and suturing generally being out of the question.

The reports on one microscopic specimen are interesting. One dermatopathologist, Satenstein, states

This type in all probability is a papillary dermatitis. From its clinical characteristics, mode of development and resistance to therapy it does not fall into the category of true plantar warts. It is, from histologic structure, more like a dermatitis with papillary outgrowth, often associated with the

MOSAIC WART

An Unusual Type of Plantar Wart

ANDREW H. MONTGOMERY, M.D. and ROYAL M. MONTGOMERY, M.D.,
New York City

Three years ago, in reporting our experience in the management of plantar warts in some 426 private patients,¹ we mentioned the unusual resistance to all kinds of therapy of a multiple, patchy variety, limited almost invariably to the sole. To this type, one of us in 1928,² from its surface characteristics, applied the term "mosaic."

Search of the literature has disclosed only two brief notes regarding it and no reference to resistance is made by either Taussig and Miller³ remark "There may be a nest of warts of nearly equal size" Andrews⁴ gives a good description

Sometimes they (plantar warts) are grouped, or several contiguous warts fuse so that they appear as one until the keratotic surface is shaved off and the multiple cores are revealed. These cores are soft and pulpy and are surrounded by a firm horny ring. They occur in no other form of wart but resemble somewhat the cores in corns.

The mosaic wart appears most commonly on pressure points of the sole in the form of a variously sized patch. It is irregularly bordered, dry, and topped by a rather granular, friable, horny mass. It is usually painless. On paring one sees an area composed of soft, corn-like segments, so closely packed that those in the central part have angular, rather than rounded, borders. The individual cell or core is usually from two to three mm. in diameter. Patches may vary in size from that of a pea to five or more cm. across. The whole gives the appearance of a mosaic floor or the face of a honeycomb.

Mosaic patches increase in size slowly but steadily. Years may pass without any apparent tendency toward undergoing involution.

We have had the opportunity many times of observing their onset and development clinically. Papillary lines on the pressure surfaces of the sole are

large and translucent, often transparent. By moistening the skin with alcohol, oil or glycerine, one can see quite deeply. The earliest lesion appears as a local widening of a normal papillary line. Sometimes two such minute growths appear side by side within a line. More and more such papillary enlargements are noted. They increase in size until definite cores with keratotic caps are found. These are to be seen best at the border of a patch or in recurrences, at the edge of an excision or electrocoagulation wound.

In new areas the process of development seems to be the same. Localized broadenings of normal lines develop into warty growths, pin-head in size or slightly larger, which fuse to form a mosaic pattern, but with each cell maintaining its individuality.

Numerous minute outlying patches may be found, singly or in groups, some superficially resembling common plantar warts, but paring shows their multicellular character. These outlying warts, separated by normal papillary lines, often give the corneous layer a moth-eaten appearance, such as one sees in mild hyperkeratotic types of ringworm. Such minute lesions never have the initial deeply seated vesicular appearance of the earliest warts of the epidemic variety.

Coincident with large mosaic patches and detached smaller patches and single lesions, there may be found widely scattered, usually single, warty lesions involving the toes or other parts of the foot, or the hands and fingers. Some resemble verruca vulgaris, but more often they are of the thinner, flat-domed fleshy verruca plana type.

We have yet to see mosaic patches on any part other than the sole, the most common locations being under the head of the first metatarsal and beneath the heel.

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 25, 1937*

character of the border of large patches prevents close shielding. On this account possibly effective doses are barred. We no longer use roentgen therapy in this type, except in rare borderline cases.

Excision by scalpel or surgical diathermy has been found unsatisfactory, both as to recurrences and scar formation. We have done excisions of patches of almost a square inch in extent, three-sixteenths of an inch beyond the border, and down through fat to fascia, coagulating bleeding points, which have been followed by recurrences at the border, and in one case by a painful keloidal scar. In these cases the resilient fat pad of the sole is almost invariably damaged by this method.

We have discarded electrodesiccation and electrocoagulation for the same reason. Both procedures in this type of wart are usually ineffective. They produce large ulcers, painful and slow in healing. In persons with thin plantar fat pads, painful callused scars may follow.

Other forms of therapy: intramuscular injections of sulpharsphenamine, bismuth or of salt solution, hemotherapy, suggestion, solid carbon dioxide, galvanism, concentrated solar rays, applications of mercury, of sulphur, and of pyrogallac acid in ointments, of acid nitrate of mercury and of strong potassium hydroxide solution—all have been tried by us, as well as others, and have ended almost invariably in failure. The result is always unpredictable and generally disappointing.

The most satisfactory treatment in our experience comprises the use of salicylic acid followed by silver nitrate. A moleskin plaster having a hole the size and shape of the patch is affixed to the affected area. Sixty per cent salicylic acid paste to a thickness of one-thirty-second of an inch is spread within the hole. This is retained in place by adhesive plaster. The application is repeated every five to seven days. At each visit the macerated tissue is cut away and a new moleskin shield, usually with a contracted hole, is applied. To be successful one must go deeply. That is especially true when one endeavors to reach the main afferent blood vessels. Salicylic acid seems to have a selective action in blanching papillary elongations, thus making it easier to trace their course and to direct therapeutic attention toward the source.

When thin rete without papillomatous structure is exposed, it is swabbed with strong silver nitrate solution (gr 1 to min 1). Several such swabbings are made, each time after paring down the black eschar.

Care is taken to protect the area from water between dressings.

Outlying patches and single lesions are treated similarly. According to size and shape, pieces of forty per cent salicylic acid plaster, reinforced with a thin coating of the paste, are applied under covering discs of adhesive plaster.

As a patch heals the affected area contracts and the normal arrangement of papillary lines is resumed, usually with

Fig 5 Large mosaic patches with scattered satellites off weight-bearing surfaces. They resembled verruca plana.

Fig 6 Mosaic wart resembling nevus.

Fig 3 Large mosaic area with scattered outlying warty elements

Fig 4 Extensive mosaic areas on heel.

development of considerable granulation tissue, and the entire process resembles that of a papillary dermatitis similar to that of dermatitis vegetans, also to granuloma pyogenicum. It may be said that it is the result of injury rather than of infection and is a hyperkeratotic granuloma. It may occur alone or in combination with isolated keratotic spots suggesting true verruca plana.

Another pathologist, from a microscopic specimen alone, could not see anything unusual in the pathology other than closely packed common warts.

The earliest visible changes seem to arise in the papillary body rather than in the epidermis. Macroscopic examination would bear out the theory that the origin of a patch is situated deeply and extends toward the surface by bifurcations of papillary structures. The main stem is not always beneath a patch. In the metatarsal area it is more often in front, the papillary extensions trailing posteriorly beneath the surface. In this location, the site of the majority of our cases, the hyperkeratotic layers are laminate, overlapping from before backward, like roofing shingles. One sees a striking example of that in removing a disc of adhesive plaster. If it be lifted forcibly from the rear one is apt to tear into the skin deeply. Hypertrophied papillae follow these layers, coming to the surface posteriorly.

We have identified eighty-four cases of this type, fifty-eight since our report of 1934. No two have occurred in the same family. Patients' ages have varied between nine and fifty-nine years, with thirty-four as the average. This age

incidence is much above that of the common plantar wart. Fifty-five cases, or over sixty-five per cent, appeared in the third and fourth decades of life. Those remaining were divided almost equally between the ages above and below this sixteen and thirteen respectively. Over eighty-three per cent were in ages above thirty years. Females were affected over males in the proportion of two to one.

Patches in fifty-eight of the series were beneath metatarsal heads, thirteen on the sole of the heel, fourteen on the big toe bulb. Only one, beneath the long arch, was not on a bearing point.

The duration of the lesions before coming to us for treatment varied between three months and twenty years. Over half, forty-three, had existed for over two years, sixty-eight for more than a year. All but six had been treated previously.

Nearly all the cases referred to us had recurred after incomplete removal by excision, electrocoagulation, and acids. Several showed postirradiation ulcers.

While we have been able to cure nearly ninety per cent of ordinary plantar warts by roentgen therapy, using a developed technique, we soon found mosaic warts to be unusually resistant to either unfiltered or filtered rays. As much as five skin units (1750r) have been given the smaller patches and two skin units (700r) to those an inch or more in diameter, closely shielded, without the usual response of desiccation or contraction. Sometimes an initial dose of four skin units (1400r) to smaller patches caused desiccation of the superficial vessels, but later irradiations made no impression. The diffuse

and progressive, and in its resistance to therapy

We believe that nonrecognition of this type of wart as radioresistant has been responsible for many unfortunate post-irradiation complications

MEDICAL THOROUGHNESS IN JAPAN

As Japan is expanding and taking a larger and larger place in world affairs, it is important to learn what the Japanese are doing along lines that are parallel to our own. A professor of the Philippine College of Medicine at Manila, Dr Regimo Navarro, recently visited Japan and made an interesting report before the Clinical Club in Manila on what he found there. He was especially impressed with Japanese thoroughness. As he said

Another very prominent trait of the Japanese, which is very clearly seen in all their activities, but of which I can judge personally only in their medical activities, is the thoroughness with which they do any job. This thoroughness is probably shown in all fields of work, in commercial, industrial, as well as in other activities. Even in their work in China you see the thoroughness with which they plan and do the job. But it is their thoroughness in the field of medicine that stirs my wonder particularly. In visiting medical institutions such as hospitals, colleges, and institutes, I found the Japanese are not prone to brag of their equipment, of their executive abilities, or of their plans for these institutions but they take intense pride in being able to carry the research activities to a point at which practically every member of the staff carries on some kind of research. This is true not only of institutes and universities but also of hospitals, but it is of greatest importance and of largest scope in the universities and institutes—I mean institutes corresponding to our Bureau of Science here in Manila. When one visits any of these places, be it a hospital, a college or an institute, he is first taken through the building for a general survey. After this preliminary showing the visitor is often asked what particular phase of the work interests him the most. Then he is shown the department which is of most interest to him, and the work in progress there, and is supplied with several pamphlets, reprints, or plans of research to be done for the next three to five years. The thoroughness of their

work is clearly evident in every branch of their scientific activities

The experimental work on cancer being carried on in the Department of Pathology of the Tokyo Imperial University is as complete and as extensive as any of which I have read. The experimental studies on the virus of encephalitis being done in the Department of Bacteriology of the same university are very extensive and comprise not only the study of the viruses but also of their symptomatology, on different laboratory animals, the pathologic changes of the same in the human and in animals, and an attempt is being made to classify different strains by serologic means. A cross immunization process is being carried on with different strains of viruses and an attempt is being made at cross immunization with strains imported from America. It is indeed interesting and very instructive to watch doctors in the Department of Bacteriology carrying on their experimental studies. Just to show the thoroughness of these people—there is even an attempt to manufacture sera for purposes of prevention and therapeutics.

In the government institute for tropical diseases, extensive work has been done on the virus of lymphogranuloma inguinale. The director of the institute takes an active part in these particular studies. He has shown the possibility of demonstrating the virus, of classifying it, of reproducing the disease and of producing immune sera. Different phases of various kinds of studies or experiments are shown the visitor, and the thoroughness with which they carry on their work is evidenced by the different phases of the subject that they plan to study and by the varied and extensive literature they have at hand on the subject.

For one who views all these marvelous scientific activities there is a mixed feeling of admiration and embarrassment—something from one's personal experience as a result of personal investigations or re-

a complete absence of scar formation and with no damage to the plantar fat-pad

The treatment outlined is somewhat painful, but it has never been necessary to incorporate an anodyne in the paste. To prevent recurrences we often prescribe a thirty per cent salicylic acid ointment, to be rubbed into the warty area nightly, using a finger-cot or the knobbed end of a wooden clothespin.

As in the case of fungous infections, persistence is the watchword. We failed in many of our earlier mosaic cases. Our histories in many are incomplete. Pa-

compared, either as to effect or after-effect with salicylic acid.

Summary

Some eighty-four cases of a compound verrucous patch with outlying satellites resembling verruca plana, are reported. Patches have never been found elsewhere than on the sole. They have proved unusually resistant to all kinds of therapy, yielding best, in our experience to repeated applications of sixty per cent salicylic acid paste, followed by swabbings of strong silver nitrate solution.

Fig 7 Extensive mosaic patches which had resisted many types of therapy. Cleared with salicylic acid paste without any scarring.

tients became discouraged and discontinued treatment or went elsewhere. Some were cured by others and we wonder by what method.

The histories of previous treatments are always interesting. We find that many have gone through the entire list mentioned above, from acids to excision, by chiropodist, surgeon, and dermatologist. Some patches have been excised twice and recurred.

Unfortunate results by others using radium, on account of its wide lateral action through a shield-hole, and because of the resistance of this type of wart, have restrained our use of that modality. For awhile we thought we were getting some cures with the half-strength plaque. We still use it with benefit on some of the smaller patches. But it is not to be

The suggestion that they are in the nature of a papillary dermatitis or a hyperkeratotic granuloma is offered.

We have found that the main root-stems are seldom located beneath a patch. To this more than to anything else we attribute the many failures, our own included, in the eradication of this lesion. In the metatarsal area the common stem originates deeply, generally anterior to the patch, its numerous bifurcations trailing backward and ending superficially in a patch, formed by fusion of individual warty bodies capping the papillary fibrils.

Lesions of verruca plana type may be found on other parts of the body.

The mosaic wart differs from the ordinary compound plantar wart in having an irregular border, spreading over large areas, in being invariably dry, painless,

fibers in both that somatic peripheral and the sympathetic nervous systems. It is possible that ordinary pain is transmitted only in this way but when the pain stimulus is extreme, undoubtedly all the sensory nerve fibers participate in its transmission.

When a pain stimulus has passed along the peripheral nerve and has reached the spinal cord by way of the posterior nerve roots, immediately a neurological elaboration of the stimulus begins to take place. In the gelatinous substance of Rolando at the extremities of the posterior horns is a complicated system of short neurones whose function is the handling of pain transmission. As the stimulus passes from one neurone to another it is likely that a change takes place in its characteristics.

The first response to pain occurs at this point. An association fiber arising here may carry the impulse to the motor cells of the anterior horn which results in the withdrawal of the injured part from the source of pain. Such a reaction being purposeful has in it some of the characteristics of the psychological.

The primary central pain tract system arises from cells in the posterior horn and these fibers ascend one or two segments before they cross the cord to the opposite side to form the lateral spinothalamic tracts which lie on the surface of the lateral white columns, where they pass upward to terminate in the medial thalamic nuclei. Here according to Strong³ the pathways undergo a thalamic diffusion and the pain sensations are carried up to the cerebral cortex by thalamocortical neurones whose anatomy is not clearly known.

Pain may be produced by stimulation or irritation at any point along the course of the pain conduction pathways. It matters not where the site of the irritation may be, the resulting sensation of pain is always felt out at the periphery where lies the sensory end organ from which the affected fiber has been wont to receive painful stimuli.

In the clinical observation of pain one may observe various pain manifestations which indicate quite clearly the separate functionings of this complicated pathway. When pain of considerable degree is inflicted on a subject, a definite sequence

of pain phenomena may be seen, each one of which implies the action of a different part of the pain pathway. When pain is great the whole occurs so quickly that no differentiation is possible. When on the other hand pain is produced more slowly the action of the various anatomical parts may be, at least in part, identified. When one stimulates slightly a painful area, such as a localized abscess or a broken bone or even pushes a pin slowly into the skin anywhere, the first reaction seen is one of withdrawal to pull the tender area away from the irritation. This is, in the main, a spinal cord reaction in the nature of a reflex, quick and unthinking but so powerful in its urge as to require great mental concentration and what is known as will power to keep it from occurring. One sees this reaction with its great speed occurring below the level of spinal cord tumors and transverse myelitis which have destroyed the spinal cord tracts so that no conscious sensation of pain can be perceived and no motion of the limb is possible.

The next level of pain expression in the intact nervous system is the thalamic which is one of feeling tone, of displeasure, of discomfort, of pain. When we speak ordinarily of pain we mean most often this thalamic part and those reactions which have their seat of origin here. It is here that those bodily changes, of which Cannon has written, have their origin. It is here that pain is really felt. One of the most accurate indicators of thalamic action is that great motor mechanism of feeling expression—the facial musculature. In states of moderate pain one sees first a slight contraction of the orbicularis palpebrae, contracting and puckering the eyelids especially at the outer angle. Then follows a dilation of the pupil and a contraction of all the facial muscles in a grimace of pain with a quick, gasping intake of the breath. As a rule the thalamic follows the spinal cord reaction very rapidly while frequently there is a definite wait before the cortical reaction is seen. This is the psychic reaction—a matter of perception, of ideas, of relative values, of language, not only of words but of rhetoric as well—simile and metaphor not to mention hyperbole. These reactions run all the way from simple grunts, cries, and other

PSYCHIC FACTORS IN PAIN

LOUIS CASAMAJOR, M D, *New York City*

Pain is as old as animal life. The sensory equipment of even the most primitive forms of animal life contains something that is at least the prototype of pain. Even the protozoa respond differently to stimuli emanating from sources valuable to the animal—food, etc.—than to those which may be dangerous or even destructive to life. To these latter stimuli the animal reacts by avoidance or flight just as do the higher organisms to what we know as pain.

One does not define pain or even attempt to classify it for pain belongs to the category of experiences which occur far below the verbal level in psychic life. It is likely that pain and pain reactions comprise the most primitive psychology. Pain consists of a group of sensations, impressions, and reactions which have as their purpose the preservation of the organism. Since such a function has to do with the future as well as with the past (memory), one can see how close it comes to that which in highest forms is known as mental activity.

When Dr. Cannon,¹ twenty years ago, brought together the results of his researches he named his book "Bodily Changes in Pain, Hunger, Fear and Rage." All these he grouped together because those bodily changes of which he wrote—blood chemistry, metabolism, and organ function—are strikingly similar under each of the conditions that made up his title. All four were definitely psychological for each one similarly affected the relationship between the animal and his environment especially in so far as this relationship bears on the instinct of self preservation.

One has but to look at the anatomy of the sensory pathways in vertebrates to note how early pain sensation and its close relative temperature sensation manifested their highly specialized nature and differentiated themselves from other forms of sensation. One of the most striking anatomical characteristics of highly specialized nerve tract systems

is their tendency to cross from one side to the other to reach a termination on the opposite side of the nervous system from that on which they arise. This is especially true of those fiber systems that go to and come from the forebrain. One gets the impression that these fiber systems whose functions have a psychological import must cross to the opposite side of the central nervous system as a part of the process of attaining such psychological import. If this be true—and what evidence we have would seem to point that way—then one would be justified in considering pain and temperature sensations the most primitive psychology for they are the only ones that complete their crossing in the spinal cord long before the brain is reached.

Pain arises as a result of the stimulation of the pain conveying nerve tract. There is still some doubt whether there are special nerve endings for the reception of pain stimuli and special nerve fibers for its transmission to the central nervous system. Free nerve endings probably can transmit nothing but pain. They are the only ones to be found in the cornea, the ear-drum, and the pulp of the teeth. Even the slightest stimulation of these areas can produce no other sensation than pain. However it is most likely that all other sensory end organs are capable of transmitting pain when the stimulus is great enough. Extremely intense light transmitted by the optic end organs and equally intense sounds transmitted by the cochlear apparatus result in pain sensations in the consciousness as well as light and sound. Whether pain from the somatic nervous system and the involuntary nervous system may not at times be similar in its peripheral causation is well within the realm of possibility.

A similar doubt exists as to whether there are in the peripheral nervous system special nerve fibers which can carry only pain. It is possible that this is the function of the nonmyelinated sensory nerve

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 25, 1937*

My only personal experience with extreme pain was the occasion of the passing of a kidney stone nearly fifteen years ago. The pain of ureteral colic is one of considerable intensity. According to the evidence of those who have experienced both, the pain of ureteral colic is more intense and severe than are labor pains. A few months after the experience I was able, in a lecture to undergraduates, to give what I thought was a good description of that pain but the following year I found I was unable to repeat that lecture, nor have I ever been able to do so since. However, I am confident that, like the patient mentioned above, I should recognize the pain at once if I should ever again experience ureteral colic.

What I have tried to show by this digression is that pain memories and pain descriptions are at best extremely inaccurate things. Psychic pain is made up much less of pain memories than of ideas of pain. To the patient psychic pain appears quite real at times but it lacks the anatomical and physiological characteristics of pain of organic origin. It is a matter of pain belief, pain idea, and pain delusion, not plain pain as we know it. It is the product of psychic activity and consists only of the cortical part of pain with the spinal cord and the thalamic components entirely absent. It consists of pain description and pain elaboration without the concomitant, tell-tale, thalamic pain symptoms that give the stamp of reality to organic pain.

Again psychic pain is likely to be unphysiological and unanatomical in that the pain picture does not correspond to known anatomy and physiology. Thus psychic face pain may often be differentiated from the pain of trifacial neuralgia by a study of the area affected. The pain of trifacial neuralgia has an exquisitely accurate anatomical localization. When one asks the patient to indicate the painful area he does so usually by outlining with the tip of one finger one or more of the areas of the trifacial nerve. The line he draws outlines an area as accurate as an anatomical chart. It goes to the midline but never beyond nor does it extend over into the sensory areas of the other branches or of other nerves. In psychic face pain on the other hand the area indicated is usually inaccurate in the

extreme. When asked to show the painful area the patient does not use one finger tip to outline an area. Rather he usually places his whole hand over an area which, in many instances, takes in parts of both sides of the face and also cutaneous areas supplied by cervical nerves only.

Again the description of the pain is often of great diagnostic importance. The pain of trifacial neuralgia defies description. It is pain and nothing else. There may be accompanying gestures in the form of thalamic facial expressions but words do not exist to cope with these thalamic memories which occur so far below the verbal level of psychic life. Reproductions of these pain memories

Psychic pain on the other hand consists almost entirely of language—adjectives and not infrequently adverbs—as well as simile, metaphor and hyperbole. Recently I saw a woman who was suffering from a pain in her face, gums, and neck following the removal of an upper tooth some ten years previously. She talked quite volubly of the pain without evidencing the slightest facial expression. Most of her talk consisted of adjective used in the superlative. Often she spoke of her sensation as pressure, as though pressure and pain were synonymous. When her attention was called to the fact that pressure and pain are not the same thing and that pressure may be an intense different or even a pleasurable sensation she was much confused and had difficulty in continuing her description once her language concepts had been disturbed.

It is a difficult matter to classify psychic pain just as it is difficult to classify any other psychic manifestation. The more one tries to be definite the greater risk one runs of being inaccurate. Clinical psychic states, in spite of their reality, are tough things to try to define and to delimit. They run with insensible gradations from the simple psychoneuroses through the hysterias and compulsions up to the frank psychoses. Psychic pain may appear as a symptom manifestation at any and all of these many levels. The less well-organized the neurotic state the less well-organized the psychic pain symptom. At the risk of being inac-

unformed pain sounds up to elaborate description. It is at the psychic or cortical level that pain is understood, so well as it can be understood, localized, compared, and talked about.

One can see from this review of the anatomy and physiology of the pain pathways that spontaneous pain may be occasioned by irritating lesions occurring at different points along the pathways. One may speak thus of peripheral pain, neural pain, ganglion pain, spinal cord pain, and thalamic pain. Peripheral pain results from local traumatic or inflammatory lesions, neural pain from neuritis and peripheral nerve tumors, spinal cord pain from cord tumors and syringomyelia, and thalamic pain from destructive and irritating lesions involving the median nuclei of the thalamus. The latter is seen especially in the so-called thalamic syndrome of Dejerme² and Roussy. This syndrome which is caused by lesions involving the thalamus anterior to the pulvinar, an area which includes the median thalamic nucleus, consists of severe, constant, intractable, subjective pain in one-half the body with complete anesthesia to objective pain on the painful side. This painful analgesia can mean only destruction of the pain conducting mechanism at its thalamic level with a constant stimulation of those fiber systems which carry the pain sensation to the cortex and the consciousness.

Above the thalamus there are no known organic lesions which cause subjective pain. The cerebral cortex itself is insensitive to pain. However stimulation of the motor cortex may occasion subjective pain in the part represented by the cortical area stimulated. I once observed the removal, under local anesthesia, of a cortical meningioma which was adherent to the motor area of the foot. When this adhesion was pulled, the patient immediately complained of severe pain in the foot of the opposite side of the body. It is possible then there exists pain localization in the cortex but most likely these are so bound up with other forms of sensation, of motion, of sensory and motor memories that pain itself cannot be separated off as an isolated function as can be done lower down in the nervous system. Cortical pain is not pain as we know it in the rest of the nervous system. It is

not a matter of lesions involving nerve tract systems, but rather a matter of pain memories, pain ideas, pain beliefs, and pain delusions. It is psychic pain which one must evaluate in terms of psychology rather than in terms of anatomy and physiology. Psychic pain may be real enough in the consciousness without any basis in nervous system pathology.

To evaluate psychic pain one must first speculate on what pain means to the individual. To some Spartan individuals there is no pain except great pain. To others, such as the hypersensitive neurotics, even moderate discomfort is called pain, often with qualifying adjectives such as "terrible," "terrific" or "intolerable." Pain is such a primitive psychological factor and so much of its functioning is confined to the lower parts of the nervous system that it is not well-organized in the psyche. Most of us have difficulty in describing the pains that we feel. Most of us just call it pain and let it go at that. We may offer comparisons such as "like a tooth-ache" but usually the language of pain is very meager. The neurotic has a more elaborate language of pain but usually this is rather barren except for hyperbole. The rapidity with which pain memories disappear from the consciousness is also indicative of the poor psychic organization of pain.

Pain memories do however persist more or less unconsciously for a considerable period of time but they do not persist in the form of words. They persist in the form of feelings which may be recognized with great accuracy many years afterwards although they may not be accessible to description in terms of language. Nearly twenty years ago Dr. Tilney and I⁴ reported this form of pain memory in a case of hemorrhage into the basal cisterns. The patient, the wife of a physician, a highly intellectual woman, suffered a severe pain in her head after having run up a flight of stairs. Before she became unconscious she told her husband that she knew she was having a brain hemorrhage because the pain in her head was so similar to that experienced at the time of her abdominal hemorrhage due to the rupture of an ectopic gestation some years before. Autopsy revealed an extensive subpial hemorrhage located mostly in the basal cisterns.

My only personal experience with extreme pain was the occasion of the passing of a kidney stone nearly fifteen years ago. The pain of ureteral colic is one of considerable intensity. According to the evidence of those who have experienced both, the pain of ureteral colic is more intense and severe than are labor pains. A few months after the experience I was able, in a lecture to undergraduates, to give what I thought was a good description of that pain but the following year I found I was unable to repeat that lecture, nor have I ever been able to do so since. However, I am confident that, like the patient mentioned above, I should recognize the pain at once if I should ever again experience ureteral colic.

What I have tried to show by this digression is that pain memories and pain descriptions are at best extremely inaccurate things. Psychic pain is made up much less of pain memories than of ideas of pain. To the patient psychic pain appears quite real at times but it lacks the anatomical and physiological characteristics of pain of organic origin. It is a matter of pain belief, pain idea, and pain delusion, not plain pain as we know it. It is the product of psychic activity and consists only of the cortical part of pain with the spinal cord and the thalamic components entirely absent. It consists of pain description and pain elaboration without the concomitant, tell-tale, thalamic pain symptoms that give the stamp of reality to organic pain.

Again psychic pain is likely to be unphysiological and unanatomical in that the pain picture does not correspond to known anatomy and physiology. Thus psychic face pain may often be differentiated from the pain of trifacial neuralgia by a study of the area affected. The pain of trifacial neuralgia has an exquisitely accurate anatomical localization. When one asks the patient to indicate the painful area he does so usually by outlining with the tip of one finger one or more of the areas of the trifacial nerve. The line he draws outlines an area as accurate as an anatomical chart. It goes to the midline but never beyond nor does it extend over into the sensory areas of the other branches or of other nerves. In psychic face pain on the other hand the area indicated is usually inaccurate in the

extreme. When asked to show the painful area the patient does not use one finger tip to outline an area. Rather he usually places his whole hand over an area which, in many instances, takes in parts of both sides of the face and also cutaneous areas supplied by cervical nerves only.

Again the description of the pain is often of great diagnostic importance. The pain of trifacial neuralgia defies description. It is pain and nothing else. There may be accompanying gestures in the form of thalamic facial expressions but words do not exist to cope with these thalamic memories which occur so far below the verbal level of psychic life. Adjectives practically never appear in the reproductions of these pain memories.

Psychic pain on the other hand consists almost entirely of language—adjectives and not infrequently adverbs—as well as simile, metaphor and hyperbole. Recently I saw a woman who was suffering from a pain in her face, gums, and neck following the removal of an upper tooth some ten years previously. She talked quite volubly of the pain without evidencing the slightest facial expression. Most of her talk consisted of adjective used in the superlative. Often she spoke of her sensation as pressure, as though pressure and pain were synonymous. When her attention was called to the fact that pressure and pain are not the same thing and that pressure may be an indifferent or even a pleasurable sensation she was much confused and had difficulty in continuing her description once her language concepts had been disturbed.

It is a difficult matter to classify psychic pain just as it is difficult to classify any other psychic manifestation. The more one tries to be definite the greater risk one runs of being inaccurate. Clinical psychic states, in spite of their reality, are tough things to try to define and to delimit. They run with insensible gradations from the simple psychoneuroses through the hysterias and compulsions up to the frank psychoses. Psychic pain may appear as a symptom manifestation at any and all of these many levels. The less well-organized the neurotic state the less well-organized the psychic pain symptom. At the risk of being inac-

curate one might divide psychic pain into three categories

- 1 Pain belief,
- 2 Pain idea,
- 3 Pain delusion

Pain belief is a simple thing and often it does not exist outside the field of attention. It has little effect on the fundamental personality and usually is not constantly incapacitating. A woman came in to the clinic complaining that her face twisted upon the right side and pained her "something dreadful." She was suffering from a left sided facial palsy. When she was placed in front of a mirror and was shown that the right side of her face was all right but the left was diseased the pain immediately disappeared from the right side of her face. When she was seen later the pain had returned, this time on the left side.

Pain idea is a more organized thing than pain belief. It occupies much more of the psychic life and has its roots much deeper in the personality. It may exist outside the field of attention. A clinic patient had for years been seeking relief for pain over one eye. It had bothered him quite a bit and fairly constantly enough to make him seek medical relief occasionally but not enough to interfere materially with his daily routine of life. The history was that one night some years ago he had dreamed that a cat bit him over the eye and ever since then he had had pain where the cat bit him. The limitations of clinic practice did not make it possible to find out what this symptom really meant before the patient disappeared from the clinic, possibly to seek the aid of doctors more in sympathy with his pain idea.

Pain delusion is a much more stubborn thing. It is a definite integral part of the patient's personality. It may even become the ruling motive of his life. Often he seems to live only for the pain, and all of his life routine is adjusted in respect to its affect upon the pain. This is intractable pain real and vital to the patient but unfortunately it is not susceptible to relief by surgical therapy nor, for that matter, by psychotherapy either. Often these patients closely simulate the paranoiacs.

A delusion is a false idea and accord-

ing to White⁵ a delusion has certain characteristics (1) It is obviously not true to facts, (2) It is out of keeping with the patient's education and intelligence, (3) It is not correctable by any appeal to reason. Pain delusion satisfies all of these characteristics and especially the latter. It may persist for years and may so occupy the patient's entire attention that he appears to be very little else besides a pain and a voice.

Pain delusion appears not frequently in the face and the mouth. In the latter location it is seen following extraction of teeth and the fitting of artificial dentures. In these cases we frequently see the burning tongue which does not appear to be amenable to any form of therapy and may last for years. The diagnosis is never easy. These patients have such firm belief in the reality of their pain that not infrequently they present a very good and consistent clinical picture. The longer one knows the patient however the more one is impressed with the stubborn, ingrown personality, that lies in the background. As a rule it takes a very definite kind of person to harbor a pain delusion and this type of personality very closely approaches that of the paranoiac.

I have talked to you at length about psychic pain touching here and there on the high spots of the subject. Some of these pains are fleeting and inconsistent while others of them are a definite part of the patient's personality. The more superficial of them are remediable by means of psychotherapy even of such simple form as suggestion. The more severe are truly intractable and since they are frequently made worse by surgical procedures which are so efficacious in organic pain, their recognition is of utmost importance where surgical intervention may be considered.

THE ACID FACTOR IN PEPTIC ULCER

With Special Reference to Milk Drip Therapy and Partial Gastrectomy

ASHER WINKELSTEIN, M D, *New York City*

From The Gastro-Intestinal Clinic of the Medical Department and The Wimpfheimer Wards for the Surgical Treatment of Gastro-Intestinal Diseases, Mount Sinai Hospital

There exists a general impression, probably founded in fact, that the incidence of peptic ulcer is increasing. This may be due to a general increase in the so-called "diseases of civilization" which include not only peptic ulcer but essential hypertension, arteriosclerosis, exophthalmic goiter, and disease of the coronary arteries. Perhaps a review of some recent theories of the cause of ulcer will throw new light on this phase of the subject.

Three theories will be briefly discussed, (1) the psychogenic, (2) the ductless glandular, and (3) the inflammatory

Psychogenic

Recently Leonard Rothschild completed a psychoanalytic study of thirty-two consecutive patients with duodenal ulcer in the Gastro-Intestinal Clinic at Mount Sinai Hospital. He found that they all gave evidence of a profound neurosis usually of a definite type. They were an aggressive, Sadistic type who were chronically frustrated emotionally. These repressed emotions seemed actually to cause the patients "to eat themselves up inwardly." Moschowitz described ulcer patients as highly irritable, commonly "swallowing their anger," with resultant gastric symptoms. Cushing concluded, "So it may easily be seen that highly strung persons through repressed emotions incidental to continued worry are prone to the hyperacidity often leading to ulcer." While a direct casual relationship has not as yet been established there should be no doubt as to the importance of psychic factors in peptic ulcer.

The Ductless Glandular Factor

Peptic ulcer is predominantly a male disease. It is approximately twelve times as frequent in males. No student of the ulcer problem should neglect this strik-

ingly unequal sex incidence. Recently, in some experimental work with gastric fundus pouches in dogs, I found that during estrus the abdominal wall erosions about the pouch orifices healed and the acid secretion from the pouches diminished. During lactation, the contrary occurred—the erosions enlarged while the pouch secretion increased. These preliminary observations suggest the possibility of a relationship, particularly of the anterior pituitary gland, to gastric secretion and to peptic ulceration. Further investigations along these lines are now in progress.

The Inflammatory Factor

Since the extensive use of partial gastrectomy for peptic ulcer in this country chiefly by A. A. Berg, a splendid opportunity for studying the histopathology of the gastric mucosa has presented itself. Practically all of the resected stomachs show a varying degree of a specific type of gastritis and duodenitis. This lesion, described extensively by Konjetzny, Puhl, and Buechner in Germany, and Aschner and Grossman in this country, reveals the following characteristics:

1 It is located chiefly in the antrum and duodenum.

2 It is erosive (erosions and acute ulcers) and infiltrative (polynuclears and round cells).

3 In general, it corresponds neither with the state of the ulcer itself nor with the degree of pyloric obstruction.

The cause of this lesion is as yet unknown. At present we are studying the following possibilities: dietetic errors, alcohol, tobacco, focal and general infections, allergy, and "the acid-pepsin plus spasm" factor. This gastritis and duodenitis probably has a great significance. It is possible that this type of lesion may

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 25, 1937

be the precursor of the ulcer disease. Furthermore, patients with symptoms of ulcer in whom ulcer is not found frequently display this specific type of erosive gastritis and duodenitis. This also should prove a fertile field for thorough investigation.

It is necessary to point out that the foregoing discussion has dealt only with some of the ultimate causes of ulcer. We will next turn our attention to the mechanism through which these causes operate to produce the lesion itself. In recent years this phase of the problem has been greatly clarified. For, all the experimental and clinical data as well as the theoretic considerations are in agreement that the following three factors are most important: (1) the mechanical, irritant, or, exogenous factor, (2) the "acid-pepsin" or "acid" factor, and (3) the factor of tissue resistance. Briefly, some evidence for the irritant factor is the high incidence of ulcer among the Abyssinians who eat mostly meat impregnated with Cayenne pepper and the high incidence among the inhabitants of India who eat hot curries. Speaking strongly for the acid-pepsin factors are the numerous animal experiments of Exalto, Mann, Ivy, and Dragstedt wherein typical chronic peptic ulcer is produced almost constantly after various anastomoses which exclude the alkaline duodenal juices (duodenoileostomy plus gastrojejunostomy, or, Pawlow pouch-ileostomy experiments). The evidence for the tissue resistance factor is less impressive but it seems quite probable that the specific tissue itself possesses protecting factors (mucin? vascularity? antiferments?).

In our clinic at Mount Sinai Hospital, we have devoted ourselves for many years to an intensive study of what seems to us the most important factor in the ulcer problem, viz, the so-called "acid" factor. We believe it to be of fundamental importance in the mechanism of ulcer formation and certainly in its medical and surgical treatment. We have been impressed by the following points:

1 Peptic ulcer (esophageal, gastric, duodenal, jejunal, Meckel's diverticulum) commences and occurs invariably in an acid medium.

2 Using a combined "histamine-neutral red-food" fractional test meal, we have been

able to confirm the dictum "no free acid, no ulcer."

3 The best results are seen with the medical cures based on acid neutralization (Sippy and "milk-drip") and with partial gastrectomy (especially in gastric ulcer where there is practically always a post-operative achlorhydria without ulcer recurrences).

Our studies of the acidity factor have led us to a new ulcer therapy. It is my purpose to outline it briefly and then later to present some studies in gastric secretion in relation to the surgical problem.

With reference to the therapeutic approach, we might propose as an axiom that "whatever measures will produce a chronic, harmless achlorhydria will benefit peptic ulcer." Unfortunately, because of the complexity of the mechanism of gastric secretion, this is a very difficult, if not an impossible task to accomplish medically. Surgically, partial or subtotal gastrectomy is the most successful method for reduction of gastric acidity. However, when we consider the magnitude of this operation, it does not seem proper to advocate surgical therapy for every chronic ulcer. And, admittedly, a fair per cent of ulcers heal and remain healed with an adequate medical therapy. We have already indicated what we consider an adequate medical therapy, viz, one in which the gastric secretion is greatly reduced. The Sippy treatment, which has as its ideal a constant neutralization, does not accomplish this aim.

We recently completed and published a study of the gastric secretion in 169 patients during the longest interdigestive period, viz, the night. In this study we confirmed our earlier findings, already published in 1930. We found that ulcer patients have a large amount of strongly acid secretion throughout the night. Normals on the other hand have little or no free acid in their stomachs during the night. Inasmuch as these nocturnal acidity curves were obtained while the patients were on the Sippy treatment, it is obvious that that method fails to accomplish what we consider the desirable state in ulcer therapy, viz, a constant neutralization of the acidity throughout the twenty-four hours of the day. All attempts to control the nocturnal hypersecre-

tion of ulcer patients with aspiration, alkali, olive-oil, and atropine failed. Because of this we have invented and instituted the following treatment for peptic ulcer.

A Rehfluss or a thin Levin tube, preferably through the mouth, is passed into the stomach of the patient and connected by a long piece of rubber tubing to a gravity flask (or an enamel or aluminum quart can) and a Murphy drip screw and indicator are interposed in the system. Milk (with or without a teaspoonful of bicarbonate of soda to the quart) is permitted to drip into the stomach at the rate of thirty-forty drops per minute—the patient receiving in all, three quarts of milk a day.

This provides adequate nutrition, fluid, and constant neutralization. Actually, many samples, aspirated during the day and night showed a negative test for free acid and a low total acidity. In patients with severe ulcer symptoms, we like to keep the tube in the stomach two or three weeks continually day and night. Thereafter we continue the drip at night for several more weeks. During the day the conventional ulcer therapy (third or fourth week of the Sippy cure) is used. In patients with milder symptoms, the milk drip during the night only seems sufficient. The method is definitely practical. We have been surprised at the willingness of very nervous individuals to take and continue the drip (this indicates a probable psychic factor). They learn quickly the details of the treatment, and in many instances, have continued the nocturnal therapy themselves for months, and even years, in several instances.

We have been impressed by these features: (1) The symptoms disappear usually in four to five hours, (2) The relief of symptoms in patients previously refractory to the Sippy, mucin, or injection forms of treatment, (3) The lowered acid curve, improvement in radiographic signs, and the excellent subsequent course in most of the patients thus treated. We are now collecting the results in some hundreds of ulcer patients who have received the milk drip treatment.

The studies in gastric acidity were continued in relation to the surgical problem. We believe that the basis of the surgical treatment of ulcer is not only the removal of the lesion itself but also the removal of the associated gastritis and duodenitis

together with a procedure which gives a resultant optimal motor activity. But, above all, the operation must reduce or abolish the free hydrochloric acid to prevent recurrent ulceration. Because of these fundamental principles we consider partial gastrectomy as the operation of choice. This has been carried out by Berg in more than 600 cases of gastric, duodenal, and gastrojejunal ulcer in the past fifteen years.

In an analysis of the preoperative gastric secretion of 122 ulcer patients, (Table I) it was found that (1) the acidity is high in duodenal ulcer and (2) in gastric ulcer the acid curve is low or normal. Postoperatively, the patients with duodenal ulcer had free acid in forty-five per cent of the cases studied and achlorhydria in the remaining fifty-five per cent. Gastric ulcer patients, on the other hand, have practically invariably a postoperative achlorhydria. In view of the important fact that we have never encountered a recurrent ulcer after partial gastrectomy in a patient with achlorhydria, the explanation of this striking difference in the pre- and especially in the postoperative acidity in duodenal and gastric ulcer patients may prove of great practical significance. We have, therefore, carried out certain investigations in these two groups of cases.

These studies were based on the following physiologic considerations. It is now generally accepted by physiologists (Babkin, Ivy) that gastric secretion is produced chiefly in two ways, *first*, cephalic or psychico-reflex phase is nervous and mediated through the vagus nerve, *second*, chemical, or, hormonal phase is chemical and depends on the absorption of secretagogues or hormones through the antrum of the stomach and their action after access to the blood stream on the secreting gland cells (Table II). (We do not regard the intestinal phase as a very important exciter normally.) Because of the fact that in partial gastrectomy the antrum or chemical phase is removed and the vagus nerve supply together with the gland cells is left intact, it seems necessary to study the two phases of gastric secretion separately. Without going into the details of these experiments we may state that, using the chewing of an orange to produce the first or nervous phase of

gastric secretion, and bouillon and histamine (which act directly on the gland cells without nerve intervention) to evoke the second or chemical phase, we found that (1) the nervous phase of gastric secretion is high in duodenal ulcer and low or normal in gastric ulcer and (2) the chemical phase of gastric secretion is normal in duodenal ulcer and definitely quite low in gastric ulcer (Chart I).

Since the response to the chemical stimulus depends on the state of the gland cell itself, it is apparent that the glands in gastric ulcer are inhibited, probably

by gastritis. We say that because the histologic studies of our resected stomachs do indeed show that the specific ulcerative type of gastritis does affect the gland cells more in gastric than in duodenal ulcer (Aschner and Grossman).

PEPTIC ULCER

December 1, 1937]

This at once gives us a clue to the almost universal postoperative achlorhydria in gastric ulcer. To investigate our idea, all the postoperative achlorhydria cases, both duodenal and gastric ulcer, were tested with histamine and neutral red (since both act directly through the gland cell itself). We found that (1) in half of the duodenal ulcer patients, the achlorhydria was apparent or false (probably neutralization by regurgitation), (2) in gastric ulcer practically all the achlorhydrias were true ones (inhibition of the gland cells) (Table III).

We may now take stock of the significance of these studies. It is apparent again that the acid factor needs strong emphasis. In duodenal ulcer, one should attack the vagus or nervous phase in order to increase the percentage of postoperative achlorhydrias. At the suggestion of the late Dr Eugene Klem, Dr A. A. Berg added subphrenic anterior vagotomy to the partial gastrectomy in twenty-four duodenal ulcer patients who had high preoperative acidity. Nineteen were observed for several years. They all felt well and sixteen (85%) developed an achlorhydria. Duodenal ulcer patients with a high preoperative acidity with partial gastrectomy without vagotomy reveal a postoperative achlorhydria only in 20% of the cases. I have also advocated as an experiment, high subphrenic anterior vagotomy plus gastroenterostomy in the surgical treatment of some cases of duodenal ulcer (a few patients thus treated have done well).

Finally, it is obvious that the duodenitis and the gastritis herein described is assuming an important role in the ulcer problem. It is probably important in (1) the localization of the lesion, (2) possibly causing the lesion, (3) increasing the acidity in duodenal ulcer and decreasing it in gastric ulcer, (4) by decreasing the acidity postoperatively, especially in gastric ulcer, it prevents recurrent ulceration. Whatever its nature—irritant, bacterial-toxic, neurotrophic, acid-peptic, or

allergic—it seems of primary importance in the ulcer problem and deserves further investigation.

Summary

1 The psychogenic, endocrine, and inflammatory theories of the cause of ulcer are briefly discussed.

2 Of the three factors involved in the mechanism of ulcer production, the "acid factor" seems of greatest importance and is chosen for presentation.

3 Chiefly because of the failure of previous medical methods to achieve a continuous neutralization of the gastric acidity throughout the twenty-four hours of the day, a new form of therapy "the continuous intragastric milk drip" is proposed and described. It is practical and the results in a large series of ulcer patients have been good.

4 Duodenal ulcer patients have a high preoperative acidity due to increase in the nervous phase of gastric secretion.

5 Gastric ulcer patients have a lower or normal gastric acidity. The low curve is probably due to a gastritis.

6 Partial gastrectomy produces a true achlorhydria in practically all gastric ulcer patients. Recurrent jejunal ulceration has not been seen when there is a postoperative achlorhydria in any ulcer patient.

7 Duodenal ulcer patients have a neutralization achlorhydria in fifty-five per cent of the cases. Recurrent ulceration has been seen in a small number (3%) of the cases with free hydrochloric acid postoperatively.

8 Subphrenic vagotomy plus partial gastrectomy in duodenal ulcer patients with a high preoperative acid curve leads to achlorhydria (Klem). Subphrenic vagotomy plus gastroenterostomy seems worthy of a trial in some cases of duodenal ulcer.

9 The significance of erosive gastritis and duodenitis in the ulcer problem is stressed.

Discussion

DR. H. WALDEN RETAN, *Syracuse*—So far, in the study of peptic ulcer etiology, no adequate theory has been developed which includes all the factors obviously present

All discussions of the etiology of this disease rest finally on the erosion of tissue, the blood supply of which has been interfered with by some means. If a terminal vessel

electrical or mechanical construction, and carefully controlled clinical evidence relative to its therapeutic efficacy

At the same time, the manufacturer is asked to submit twenty copies of all the advertising matter, descriptive literature, labels, pamphlets, form letters, and a unit of the apparatus to be considered as it is supplied to the trade. The information obtained from the submitted material is collected at the headquarters office and turned over to the members of the Council through the aforementioned bimonthly bulletin. Advertising of similar accepted products is compared with the advertising under question, and then the Council checks it independently.

For each submitted product a member of the Council acts as referee for all the assembled material which is sent to him for his criticism. He presents a report to the Council on the efficacy of the product and the consequent acceptability or nonacceptability of the claims made for it. He reports the existence of any conflict with the Council's rules. He may and frequently does secure the services of a consultant not associated with the Council or in any way interested in the product or the manufacturer. The burden of proof for the physical and therapeutic efficacy of a device rests on the manufacturer. He is expected to engage the best technical assistance available to determine and present the evidence for the submitted product. The Council, when necessary, makes its own investigations.

In certain instances the submitted product, with evidence and advertising matter, may be referred to one of the standing committees of the Council for investigation and report, especially if a new principle is involved.

The referee's report is in turn presented to the Council members through the bulletin. In two weeks the report is discussed, and two weeks later a vote is taken, all by mail. A three-fourths majority vote is required for acceptance or rejection of a product.

In many cases, the product is not definitely accepted on the first report, but the manufacturer is informed that the product will be accepted when certain requirements are fulfilled or if certain evidence can be submitted, provided the

product is of an acceptable type, that is, has a place in physical therapy.

If the product is not accepted, a statement is drawn up for publication, which the Council adopts and sends to the manufacturer before publication. Quite frequently the manufacturer will ask that the statement be withheld from publication and agrees not to promote the product while he investigates it further. The Council grants many such requests.

The Council reserves the right to investigate products on its own initiative even though the manufacturer does not make application. In such cases, the statement of the Council which is authorized for publication is not sent to the manufacturer in advance of publication unless the Council for some reason, makes an exception to its ruling.

The Council on Physical Therapy was established primarily for the benefit of the medical profession and indirectly for the benefit of the public. Hence, it does not seem out of place to suggest here that the members of the Council have a right to ask for the support of the profession. They are working absolutely without pay. It is reasonable to feel that physicians believe the movement a good one, deserving all the support the profession can give it. The members of the profession can facilitate the work of the Council by

1. Securing a list of accepted apparatus* from the Secretary of the Council and giving preference to these devices when purchasing equipment,

2. Inquiring of manufacturers whether their products have been submitted to the Council and if submitted and refused recognition, why? If not submitted, why not?

3. Asking salesmen who call if the apparatus has been presented to the Council and accepted and, if not, explaining that no more time can be given to his product until this has been done,

4. Examining the advertising pages of the medical journals, which are supported by the profession, and, if nonaccepted products are advertised, inquire why?

THE DUODENUM

Roentgenologically Considered and Including One Case of Primary Carcinoma

WILLIAM E. HOWES, M.D., *Brooklyn*

Radiation Therapist and Clinical Director, Brooklyn Cancer Institute

The duodenum is a proportionately short, relatively fixed segment of the small intestine. It takes its name from the fact that its total length is not over the breadth of twelve fingers¹ namely, about twenty-five cm and with its diameter approximately four cm. It lies mostly retroperitoneal and its course can be theoretically visualized as that of a capital "C"².

Dr. Golden, in his text,³ divides the duodenum into three portions.

The first portion, the bulbous duodenum (duodenal cap), begins at the distal end of the pyloric channel and passes upward and slightly to the right, less often to the left, where it turns backward. It usually overlies the right margin of the spinal column. The second portion, the descending limb, just below its junction with the first portion, plunges behind the peritoneum and passes downward a variable distance along the right margin of the spinal column, often curving slightly to the right. The third portion turns to the left, forward and usually slightly upward, crosses the spine, and then continues upward and to the left a variable distance, turning to the left and forward at the ligament of Treitz to join the jejunum.

The relationship of the duodenum to the surrounding structures² is as follows:

Superiorly it is in contact with liver (quadrate lobe) and the neck of the gall bladder and forms the lower boundary of the epiploic foramen, anteriorly with the liver and (often) the transverse colon, inferiorly and posteriorly with the head of the pancreas below, and with the common bile duct, hepatic vessels and portal vein above.

The bile and pancreatic secretions enter the descending duodenum at the ampulla of Vater on its mesal wall in about the middle third.

Physiology

Much of the function of the duodenum

was understood before the advent of gastrointestinal roentgenography. On the other hand, the direct visualization of the duodenal contents under the fluoroscope and on the x-ray films has done much to clarify this knowledge. The duodenal cap fills gradually to its capacity and then empties rapidly, the emptying often in rhythm with each second or third gastric peristaltic wave, which reach and open the pyloric sphincter. The opaque meal then passes through the descending and horizontal segments in a relatively rapid progression, being divided by imprints of the mucosal folds into a feathery consistency.

Pathology

In spite of the shortness of the duodenum, its relatively protected position, and the rather transient part it plays in the digestion of food, it is possibly subject to as frequent and as varied a number of lesions as are seen in any other intestinal segment.

Its relationship with the stomach, colon, gall-bladder, liver, pancreas, and retroperitoneal lymphatics, all make it vulnerable both to involvement and pressure defect from enlargement of these neighboring organs, and to extension of new growth originating in these structures.

Sante⁴ catalogues deformities of the duodenum under (1) ulcer, (2) adhesions, (3) tumors, (4) diverticulum, (5) pressure defect on both bulb due to gall-bladder, and (6) obstruction.

In this paper an attempt is made to depict these deformities, giving a short synopsis of the findings with case reports, x-rays, and pathological sections.

Ulcer. We are all familiar with the ragged spastic duodenal bulb, its spasm so great and its filling so transient that no ulcer niche is visualized (Fig 1).

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 25, 1937

The usual deformity of the bulb originally demonstrated by Cole⁵ may be due to contracture of the circular muscle fibers or a niche defect.

Besides the possibility of hemorrhage there is the second danger of perforation and resultant peritonitis. At times perforation has been demonstrated by a linear gas shadow just under the diaphragm usually on the right side.

Adhesions. Many bizarre patterns seen on the x-ray films may result from adhesions to the duodenal bulb (Fig 2). Following gall-bladder surgery it is often difficult to differentiate adhesions from deformity due to scar following an old ulcer. Gastric surgery also may result in adhesions about this region. The following case illustrates this point.

A white male, forty-two years of age, was admitted to the Surgical Service of Dr Joseph Tenopyr at the Caledonian Hospital,

April 5, 1936, with a history of upper abdominal pain relieved temporarily by eating. His story dates back twelve years, one year previously he had had his gall-bladder removed at another institution. Following operation his pain was more severe and continuous and was not relieved by meals. The x-ray report was duodenal ulcer, peritort the first portion of the duodenum in such a way as to have produced a pseudodiverticulum. A posterior gastroenterostomy was performed. The surgeon's note stated that the duodenum was explored by palpation, induration was felt in the mass of adhesions and omentum which was attached to the gall-bladder bed. This mass was not disturbed.

A second case in this group is that of M O, female, aged forty-nine, admitted to the Brooklyn Cancer Institute, February 2, 1937 and discharged as improved March 1937 (Fig 3). Her chief complaint was low back pain of three months duration.

She gave a history of having had her gall-bladder removed at another institution in October 1936, because of the same type of pain. She had lost practically 100 lbs in the past seven months and was admitted with the provisional diagnosis of carcinoma of the pancreas. This was apparently confirmed by the x-ray films, which showed marked distortion of the descending lumb of the duodenum. However, due to the fact that the pain was relieved by diathermy and her general condition improved somewhat during her stay in the hospital and as no mass could ever be palpated, it was concluded that she was suffering from adhesions between the first portion of the duodenum and the gall-bladder bed. Following her discharge she developed a severe jaundice and was admitted to a neighboring hospital where an exploratory laparotomy was done. The surgeon found a tumor in-

Fig 1 Duodenal ulcer

Fig 2 Duodenal ulcer Adhesions following cholecystectomy

caudal a site for injection of the alcohol or elevation of the pelvis to too high a position, may result in such injury to the sacral nerve roots. Stern warns against the use of one c.c. doses of alcohol at the third lumbar level, because in this region the sympathetic innervation of the bladder can be readily destroyed. He recommends a dose of eight minims of alcohol. This point of caution may not be of such great significance, however, as it has been shown that the hypogastric nerve may be severed without bladder paralysis.

A very small number of cases receiving subarachnoid spinocaine anesthesia develop headache, nuchal rigidity, and

even cranial nerve paralysis. Alcohol, being considerably more toxic than spinocaine, one would expect complications after alcohol injection to appear much more frequently. This inference is borne out by the large number of complications already reported in the literature on intraspinal alcohol injection, a literature only six years old.

Discussion

DR MOSES KESCHNER, *New York City*—The case presented by Dr. Kessler well illustrates that the subarachnoid injection of pure alcohol for the relief of pain from peripheral vascular disease is by no means an innocuous procedure. In Dr. Kessler's patient the neurologic picture following the injection of alcohol into the spinal canal was indicative of a severe meningeal reaction and an affection of the cord and nerve roots resembling that described by Dr. Davison and myself (*Arch Neurol & Psych.*, 29 600, 1933) as toxic myelopathy. Histologic examination of the spinal cords in our cases of toxic myelopathy disclosed that the peripheral zones of the cord were more affected than the center. Similar observations were recorded by Weil and others who studied experimentally the effects of toxins on the spinal cord. Weil by applying saponin to the spinal cord in animals produced a pathologic picture resembling that in our cases of toxic myelopathy.

The literature is replete with reports of cases in which complications similar to those in Dr. Kessler's case followed the intraspinal injection of pure alcohol for the relief of pain in peripheral vascular disease. Such complications have been observed even in cases in which the injections were performed with strict compliance with the technic as described by the proponents of this method of treatment.

It must also be pointed out, that as far as the relief from pain in cases of peripheral vascular disease is concerned, intraspinal in-

jections of pure alcohol offer no advantages over peripheral nerve sections. This conclusion is based on the case presented here as well as on a critical review of the cases reported in the literature.

In connection with intraspinal injections in general, we also wish to sound a note of warning as the employment of spinal anesthesia in operations below the diaphragm. By this we do not mean to discredit the beneficial effects of this method of inducing anesthesia in proper cases, but we do wish to call attention to the fact that neurological complications following the use of spinal anesthesia are not at all rare. Among such complications are Paresis or palsy of one or both abducens nerves (these are most frequent), of the oculomotorius, trifacial, facial, cochlear, and vestibular as well as hypoglossal involvement have been observed. Lesions of the cauda equina, cord, nerve roots, meninges, and even of the brain have been described. Some of these complications may be slight and transitory, others permanent and even fatal.

The pathogenesis of these neurological complications is not as yet understood. The entire subject calls for cooperative investigations by surgeons, neurologists, and chemists. In the present state of knowledge it would be well that surgeons acquaint themselves with the frequency and nature of the neurologic complications so that they may limit intraspinal anesthesia to those cases in which for some reason or other general anesthesia is contraindicated.

A Louisville, Ky., newspaper recently recorded the death of a man on page one and carried an advertisement on another page in which his picture appeared together

with the statement that after taking three bottles of a patent medicine he felt "like a new man."

—Ohio State Medical Journal

THE THYROID GLAND

From the Standpoint of Pre- and Postemployment Appraisal of the Applicant for Work

EMIL GOESTCH, M D , *Brooklyn*

Thyroid disease, in both its mild and severe forms, is of relatively common occurrence in the general population. Because a mild hyperthyroidism, which is not disabling, may progress and because the fully developed disease is definitely incapacitating, the discovery of an existing hyperthyroidism becomes of great importance in the selection of employees from the large number of applicants seeking employment. By proper selection of the employee, injustices to both partners in a work program—employee and employer alike—are avoided.

The first problem that presents itself is the pre-employment physical appraisal of the applicant, with respect to his or her ability to earn a living. Since thyroid disorders, when mild, may cause little or no physical disabilities but may, when allowed to progress, be responsible for serious disabling symptoms, the factor of prime importance for estimation of immediate and ultimate disability is a proper diagnosis. I shall make brief reference to the more common types of thyroid disease.

The first type to be considered is the so-called simple colloid goiter. This is a condition, in which there is mild to moderate enlargement of the thyroid gland due to distension with colloid, and which is associated with little or no serious hypothyroidism and therefore responsible for little or no physical disability. It is common in the Great Lakes region of this country, but is relatively rare on the Atlantic seaboard. The patient with simple colloid goiter has, as a rule, a stable nervous system, a fairly good physical make-up, a slight tendency to inactivity, a slow and often subnormal pulse, some tendency to gain of weight, and a basal metabolic rate which is normal or moderately below normal. Unless the condition is advanced, it does not seriously interfere with work efficiency and rarely

causes disability in future years, particularly if simple medical treatment is instituted, such as the administration of small amounts of iodine and thyroid extract. To seriously question the ability of an applicant to hold a position, and to refuse employment on the basis of an existing simple colloid goiter may work a serious hardship on the applicant without at the same time safeguarding an employer.

A simple colloid goiter, associated with hypothyroidism, does not require surgical resection unless it is causing definite pressure symptoms or an unusual cosmetic disfigurement. Pressure symptoms, due to simple colloid goiter, and of sufficient importance to be noted by the patient, are so rare as to be almost negligible. Accordingly, interference with phonation, secondary to pressure upon the recurrent laryngeal nerves, is most uncommon. It is well to remember this fact in appraising the qualifications of an applicant for a position requiring a clear voice, as in certain types of work common in telephone companies. Some years ago I was asked to see a young woman of eighteen or nineteen years of age, who had a visible enlargement of the thyroid gland and who showed no disabilities upon physical examination. She was refused employment in the telephone company of another state for fear of the possibility of interference with her voice, and was promised employment if thyroid resection were carried out. To her the matter of employment was of such importance as to influence her to plead for operation. This was finally undertaken, against our better judgment. A limited resection was performed and her employment followed. I cite this instance, as an example of pressure exerted toward the performance of a needless operation and of hardship worked upon an applicant for employment.

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 25, 1937*

The hyperthyroid syndromes are far more difficult to differentiate and to appraise than the hypo-conditions just mentioned. Functional neuroses of all degrees of severity are common, and require careful differentiation from true hyperthyroidism with which they may easily be confused. In fact, at times the differential diagnosis may be well-nigh impossible. A mild functional neurosis is not incompatible with a high degree of efficiency. I believe that individuals with a mild neurosis, as well as those subject to mild hyperthyroidism, frequently become very loyal and conscientious employees, who take their responsibilities to heart, and are thus more to be prized than their more phlegmatic sisters of relatively inactive nervous systems.

The functional neuroses of the so-called sympathetico-tonic type have many symptoms and even signs which overlap into the realm of true hyperthyroidism. Outstanding symptoms and signs are the generally nervous state, the tendency to fatigue, the vasomotor instability, tachycardia, tremor, and emotionalism. There are many neuroses which would disqualify an applicant for work. It would be impossible to fully consider these at this time. However, functional neurosis, of the so-called sympathetico-tonic type, is worthy of further consideration because of the similarity of its symptomatology to true hyperthyroidism. It is secondary to a hypersensitivity of the sympathetic nervous system, also characteristic of hyperthyroidism. Many of the outstanding symptoms and signs are common to both conditions.

Thus we find a generally nervous state, a marked lability of the pulse with unusual tachycardia especially under emotional stress, a tendency to fatigue, vasomotor instability, tremor, and emotionalism. If these symptoms in sympathetico-tonia are not too severe, and, more particularly, if they are present only under times of emotional stress, as during physical examination or competitive tests, they should not disqualify a candidate for employment, since they do not ordinarily interfere seriously with work efficiency. I have in mind two sisters, who visited me at intervals over several years and who complained of symptoms characteristic of the condition described.

I eliminated the factor of the thyroid gland and dismissed all possibility of operation. It was not unusual for these individuals, upon entering the examining room, to develop vasomotor flushes, tremor, throbbing, and a tachycardia as high as 160, whereas the pulse was only slightly above normal when these patients were at home and free of emotional stress. In the meantime they were efficiently carrying on their duties as school teachers and had consulted me, not because of physical disability or incapacity for work, but merely because of the annoying symptoms which were ordinarily unobservable.

I mention these facts to emphasize that certain functional neuroses should not necessarily disqualify an applicant for work. If employment is granted to such an applicant, the employer does not assume the risk of future physical incapacity of the individual. There are however certain neuroses, which interfere with work efficiency and which may briefly be considered. Not uncommonly the symptoms of sympathetico-tonia are associated with various phobias—fears of fainting, heart disease, dying, accident on the streets or in the subways, inability to care for oneself unless accompanied by another person, etc. In my experience these symptoms, characteristic of an anxiety neurosis, are of bad prognostic omen and most difficult to eliminate. They are naturally incapacitating for useful employment, tend to grow worse, and should be looked for in every obscure nervous syndrome. Incidentally, they rarely occur in true hyperthyroidism and, in instances of rare association with thyroid disorder, are not relieved by thyroid resection. In fact, I have come to regard the occurrence of phobias of various kinds in a nervous syndrome, as a differential diagnostic finding which excludes the thyroid gland and hyperthyroidism as the causative factor.

The sympathetico-tonic individual can usually be differentiated from the true hyperthyroid person by the fact that the nervousness in the neurosis is a familial trait and has been present as long as the patient can remember, whereas the characteristic nervousness of hyperthyroid individuals has a definite starting point, various phobias are common in the neuroses but much less common in hyper-

thyroidism, the differential findings in the thyroid gland in the two conditions are almost pathognomonic. The gland is little or not at all enlarged in the neuroses and there are no findings such as nodules or signs of increased vascularity, whereas it is the exception to find real degrees of hyperthyroidism unassociated with glandular enlargement, the presence of adenoma or signs of increased vascularity. Finally, the basal metabolic rate in the neuroses is commonly below normal, whereas in hyperthyroidism it is elevated in degrees proportional in general to the severity of the hyperthyroidism. Having made this differentiation, the medical examiner would not assume undue risk of employment of the person with mild sympathetico-tonic symptoms, since they are rarely caused to increase to alarming degree by employment. On the other hand, failure to recognize the early case of hyperthyroidism may work injustices upon both employee and employer alike. The employee may break down in employment as a result of a subsequent severe hyperthyroidism and the employer may be forced to assume liabilities for which he is not responsible.

There are eventualities which must accordingly be anticipated should employment be given to the person suffering from a mild hyperthyroidism. These eventualities are difficult to foresee. There is always the possibility that the type of employment may react unfavorably upon the physical status of the individual, and lead to a more severe hyperthyroidism, which may result in certain claims against the employer. On the other hand, there are unquestionable cases of hyperthyroidism which continue in mild form for years without being badly influenced by work, and which may undergo spontaneous improvement. What will happen to a mild hyperthyroidism under the influence of employment is difficult to estimate. Should a more severe form of hyperthyroidism arise, it is my belief that it probably would have arisen regardless of the work the person was doing unless, to be sure, the type of work was unreasonably difficult, or nervously exacting or fatiguing. Progressive hyperthyroidism is so commonly seen in patients who are able to have the best of care,

rest, and freedom from anxieties that it is difficult to believe that the type of work was the causative factor in the increase of the hyperthyroidism and the development of a definite visible goiter. It may be difficult to convince a judge or an opposing jury of this fact and it therefore behooves the employer to exercise great care in the selection of the employee at the start. I believe it is virtually impossible to anticipate the eventualities which may arise in the future course of a mildly hyperthyroid individual.

However, I believe one should keep in mind the fact that the disease has a very predominating tendency to progress, regardless of anything we may do under the circumstances, and one should be guided accordingly.

Not uncommonly, occasion arises to estimate the physical capabilities of a person upon whom thyroidectomy has been performed. Such an individual deserves a just consideration and should not be offhand or automatically put into a substandard physical group and be handicapped, merely by the history of having had thyroid disease. The thyroid surgeon is familiar with the excellent results obtained in the great majority of patients who have suffered with hyperthyroidism, and who have had a properly directed and executed thyroid resection. The operation removes the disability and restores work efficiency. The patients are quite generally able to return to their former occupations, and, in fact are in a position to seek employment in any average type of work. There is no particular reason to believe that the individual, following thyroid operation, will not be able to continue work, give efficient service, and earn a living. The chances of recurrence of thyroid disease, after a properly performed thyroidectomy, are very small indeed. Accordingly, the risk involved in continued employment of such a patient is no greater, I believe, than in any other individual. The employee after thyroidectomy for hyperthyroidism, is physically competent to resume the ordinary day's work, and the fact, that she has learned how to save herself, may make her a preferable employee in that she does not waste her energies in useless activities but spares

herself for the necessities of her employment

It is difficult to foresee the future course of a case of mild hyperthyroidism, and impossible to predict where true hyperthyroidism is going to strike. We frequently see exophthalmic goiter arise, as it were, out of a clear sky, without definite premonitory signs and symptoms, and subsequently develop into an acute form, all in the course of a few weeks to months. Thus the disease may spontaneously arise in an employed person, who in a previous examination or interview appeared to be in excellent health. The reasons for this sudden appearance of hyperthyroidism are entirely obscure and, in fact, the etiology of exophthalmic goiter is still shrouded in mystery. I have seen this disease arise in persons who had previously enjoyed excellent health and who had expressed themselves as not "having had a sick day in their lives." Naturally there is no examination that could possibly eliminate these persons seeking work and the possible development of hyperthyroidism is a risk that must be assumed in the general problem of insurance and employment.

Not infrequently claims are made by an employee, that thyroid disease, which was first noticed during employment, was caused by the nature of his work. With the more liberal interpretation of liability, and the extension of insurance and compensation, there has been an increased tendency on the part of employees to claim remuneration for disease or exacerbation of disease, which is attributed to their work. Since we do not know the cause of exophthalmic goiter, and since it may arise under any conditions and at almost all ages, it is difficult to establish any causative relation of the type of work to the disease. Naturally, a highly nervous or exacting type of work will exacerbate a mild or underlying hyperthyroidism, but to be the cause of exophthalmic goiter is another matter entirely. I had occasion recently to testify in a case of claim of an employee against his employer. The claim was that the lifting of heavy boxes, with one of which he fell on an occasion, caused his exophthalmic goiter. On further investigation it was found that indisputable evidence of incipient thyroid disease

existed before his employment in the lifting of heavy weights. I have encountered claims for compensation in the case of toxic adenomatous goiter developing in the course of employment. Here again it is often found that a nodule was present, perhaps years before and finally became toxic, synchronous with the employment at a particular kind of work. On the other hand, the nodule may first have become noticeable during employment and thus attributed to the nature of the work. Here again diagnosis becomes important and an understanding of the nature of the underlying pathology is necessary. Bearing in mind that adenomata arise as microscopic nodules as early as puberty or before, and only become visible in later decades, after slow growth in the interim, and that they are essentially benign neoplastic formations, it is entirely unreasonable and indefensible to claim that employment could initiate a thyroid new growth or cause a latent quiescent adenoma to become toxic. The etiology of toxic adenoma is little understood, and it is generally conceded that the occurrence of toxic adenoma has no relationship to the type of work.

The disposition of an employee, having developed hyperthyroidism in the course of employment, at times presents certain difficulties. Unwarranted claims are made for compensation and attempts are made to hold the employer liable for disabilities in no way causally related to the type of employment. The choice of treatment must be determined, with the thought always in mind of the earliest restoration to health and physical ability to resume work. In a case of mild hyperthyroidism without much disability, simple medical measures may suffice. In the frank, typical case of hyperthyroidism, whether due to exophthalmic goiter or toxic adenoma, surgery offers the best prospects for prompt relief of symptoms and restoration of physical efficiency. Medical, x-ray, and other treatment is at best prolonged, dubious, and most often inadequate. The period of disability is, in many instances, a matter of years and the economic responsibilities of the employee, and possibly the employer, become unbearably burdensome as, in the end, resort must still be made to thyroid resection.

Some time ago I saw in consultation an employee who, for more than a year, had been enjoying disability benefits which he seemed to prefer to making the effort to regain his health and his job. He refused operation for exophthalmic goiter, which was advised by the medical staff of his employer and consultants, while his own family physician upheld his unwillingness to submit to surgery. An interesting legal point arises as to what extent the employer may urge or insist on operation, which practically assures the restoration of physical efficiency for re-employment, when circumstances are such that medical treatment has definitely failed and surgical treatment is refused by both the patient and his family physician. I believe that hyperthyroidism, whether due to exophthalmic or adenomatous goiter, should be treated by surgical measures. The period of disability and convalescence is relatively brief, the chances of recurrence are negligible, and the prospects for continued efficiency are good.

Parenthetically I may sound one note of warning with reference to the treatment of goiter with iodine. It not infrequently happens that lay persons, and this naturally applies to employees, receive iodine self-administered or prescribed by a well-meaning physician with

the result that the symptoms of hyperthyroidism are markedly exacerbated and the risk of operation definitely increased. Iodine, even in small doses, should not be given as treatment to a patient with hyperthyroidism, but should be reserved strictly for the preoperative period.

Summary

Thyroid disease is a not uncommon disability and should be kept in mind in the employment appraisal of the applicant for work. Simple colloid goiter does not interfere with work efficiency particularly if medical treatment is instituted. The hyperthyroid syndromes are apt to be disabling, while many of the minor functional neuroses which should be carefully differentiated from them, are not. The possibility of goiter and hyperthyroidism occurring during employment cannot be foreseen but the cases of mild hyperthyroidism which may subsequently develop serious symptoms, can be eliminated by careful physical appraisal before employment. Goiter with definite hyperthyroidism, arising in the course of employment, should be treated surgically for the prompt removal of disability and restoration to work efficiency. Iodine should be avoided in the treatment of hyperthyroidism.

142 JORALEMON ST

Discussion

DR. W. S. McCANN, *Rochester*—I do not feel competent to discuss all phases of this very interesting paper of Dr. Goetsch's, since I am not myself an industrial physician. One phase, however, is of very great interest to me. That is the effect of thyroid disease upon the muscular efficiency. You will recall that a number of years ago Boothby of the Mayo Clinic discovered that the mechanical efficiency of patients with thyroid disease whose basal metabolic rates were forty to fifty per cent above normal were only about half as efficient mechanically as normal. When we consider the normal man as a power machine, we find that he has a net efficiency of about twenty per cent, that is, if he performs work with a heat equivalent of 100 calories he will have to produce in his body 500 calories over and above his basal metabolism for the period of the work. By his net efficiency we mean that he uses twenty per cent of his extra heat production for effective external work and eighty per

cent dissipated as heat. A patient with hyperthyroidism doing the same amount of work would probably consume at least a thousand calories bringing his net efficiency down to ten per cent but requiring for this amount of external work twice as much extra metabolism with its resultant effect upon the respiratory and cardiac mechanism.

It seems to me that in this question of the relation of thyroid disease to employment the nature of the man's job would be one of the major considerations. For instance, an iron moulder pouring heavy castings and required to do heavy mechanical work would have to be mechanically efficient and it would seem obvious that his thyroid condition should be corrected.

Concerning those patients with prominent sympathomimetic symptoms with or without hyperthyroidism, my experience has been that the disturbance in the vegetative nervous system goes on more or less independently of the hyperthyroidism. That is, it may persist

even after the basal metabolism has been brought to normal by a partial thyroidectomy. Such patients are very adversely affected by nervous strain of any kind and such strains are frequently encountered in plants in which the management puts on a very high pressure

in order to "step up" production. Such patients, it would seem, would be very poor subjects for nerve-racking jobs of any kind, though they might be useful in many types of employment in which they could be given less exacting tasks.

ROUND TABLE DISCUSSIONS ON SYPHILIS, ETC

Beginning December 4, a series of Saturday morning round table discussions on venereal diseases will be conducted at the New York City Health Department Building by the Bureau of Social Hygiene. These will be most informal conferences, open to all practitioners of the city, the purpose of which will be to help clarify difficult points in diagnosis, treatment, and management of venereal diseases by the general practitioner.

For reasons of convenience in organization, one main topic will be considered at each session, together with clinical demonstrations, wherever possible, and distribution of appropriate literature.

All members of the medical profession are cordially invited to attend and to participate freely in the discussions, asking questions and citing their own particular problems. It is intended to hold these conferences, depending upon the response and

the demand, at frequent intervals thereafter. Examples of the suggested topics to be discussed are Syphilis—Diagnosis of Primary and Secondary, Treatment of Early Syphilis, Management of Latent Syphilis, Gonorrhea in the Male, Gonorrhea in the Female, Vaginitis, Lymphogranuloma Inguinale, Chancroid.

The talking motion picture on syphilis, produced by the American Medical Association and the United States Public Health Service, will be shown at this meeting at 9 30 A M promptly, followed by a discussion and demonstration of primary and secondary syphilis. Members of the staff of the Bureau of Social Hygiene possessing special experience and qualifications will lead the discussions.

Meetings will be held in the Conference Room, on the second floor of the Health Department Building, 125 Worth Street, New York City, from 9 30 to 11 30 A M.

A MILLION NEW GONORRHEA CASES EVERY YEAR

According to R A Vonderlehr and Lida J Usilton, Washington, D C (*Journal A M A*, Oct. 30, 1937), annually in the United States at least a million persons acquire gonorrhea.

The incidence of gonorrhea is highest in cities of from 50,000 to 500,000 population, and lowest in metropolitan and rural areas. The mean age of acquiring the infection is twenty-nine years for the white male, twenty-four for the Negro male, and twenty-four for the white female. The age of highest frequency of infection is several years younger in each instance.

A fourth of the cases of gonorrhea occur in females, eighty-six per cent in the reproductive period of life. Thus approximately 230,000 potential mothers in the United States acquire gonorrhea annually. There

are constantly under observation and treatment 493,000 persons with gonorrhea in the United States.

There is no substantial evidence that gonorrhea is on the decline in the United States. However, the medical corps of the armed forces of the United States has demonstrated that something can be done in the control of gonorrhea with the methods at present available. A few European countries have reported a decline in the number of cases of gonorrhea, although in no instance is it as marked as the downward trend for syphilis. The percentage of gonorrhea under treatment in public clinics decreases with the decrease in the density of population. Gonorrhea is much more prevalent than any other serious communicable disease.

A Freshman medic stated that carbon monoxide poisoning is the same as auto-intoxication—*Nebr State Med Jour*

It is still true that it is more important to know what sort of a patient has a disease than what sort of a disease a patient has.

ABSENCE OF PULSES IN UPPER EXTREMITIES

H B FEUERSTEIN, M D, *New York City*

A. S., female, age thirty-eight, housewife, was first seen in the Medical Clinic of New York Post-Graduate Medical School and Hospital on June 15, 1935

The patient was of small stature rather delicate, and did not seem acutely ill. Her chief complaint was dizziness and weakness over a period of six months. The family history was negative, childhood illnesses were grip and measles. In 1918 the patient was confined to bed with pain in the legs for three weeks (diagnosis undetermined). She had corneal ulcers in 1933 (etiology unknown) and a tonsillectomy performed in 1934.

Physical examination of eyes, ears, nose, and throat was negative. The lungs were likewise negative. Examination of the heart showed the apex beat in the fifth space, midclavicular line, no murmurs, fair muscle quality, rate 120. The abdomen and lower extremities were also negative.

No pulses could be felt in either wrists, cubital fossae, the inner aspect of the upper arms or axillae. There were no temporal pulses. The carotid pulse on the right side was very faint, the left was not palpable. The only distinct pulsations that could be felt were over the abdominal aorta, the femorals, the popliteals, the tibials, and the dorsalis pedi. We can therefore assume that the branches arising from the aortic arch have been in some way affected, while those coming from the descending aorta are apparently normal. No blood pressure readings could be obtained in the upper extremities. The blood pressure in the right leg was 155/95 and in the left leg 175/90.

Radiographic examination of the heart shows it to be normal in all its dimensions with no evidence of any aneurism, the lungs were likewise negative. The electrocardiographic tracing showed nothing but a simple tachycardia.

The Wassermann was negative, the urine was essentially negative, skin temperatures were normal for both upper and lower extremities. The blood count was

RBC 3,620,000, WBC 8,250, Hgb seventy-nine per cent, Color Index 1.09, Polys forty-nine per cent, Lymph forty-five per cent, Monos one per cent, Eos five per cent.

A search of the literature reveals only three similar cases reported. One reported by Shikhare¹ came to autopsy and revealed a fusiform aneurism of the aortic arch occupied by a large antemortem clot obliterating almost the whole of its lumen. The other two cases^{2,3} were not followed to their termination.

The patient is still under observation and claims that her symptoms have partially disappeared.

The tentative diagnosis is (1) Coarctation of the aorta and (2) Congenital anomaly of the arteries of the upper extremities.

VENEREAL DISEASE SERVICE TO PHYSICIANS

In connection with the Venereal Disease control program, the Bureau of Social Hygiene of the Health Department of New York City, wishes again to call attention to the services rendered private physicians.

Through the cooperation of the New York State Department of Health and the United States Public Health Service, free drugs for the treatment of early syphilis, congenital syphilis, and prenatal syphilis in private patients are offered to the practitioner without regard to the economic status of the patient. Diagnostic and laboratory service, including darkfield examinations, serologic tests, examination of smears, and

spinal fluid examinations, is also rendered to private physicians for their own patients at various centers throughout the city.

Follow-up service for lapsed syphilis cases of private physicians is an important feature, in no case will this be done without the express request of the physician for such action, and investigators or nurses will represent themselves as coming directly from the doctor, and not the Health Department. Every effort will be made to induce patients to return to their own doctors.

For additional information, address the Bureau of Social Hygiene, Department of Health, 125 Worth Street, New York City.

Preventive Medicine

Prevention of Mental Illness

CHARLES H. GOODRICH, M.D., Brooklyn
Presidential Address

There are layers or strata of knowledge which might be likened to geological formations. Some of the content is exposed and accessible to all persons whether or not they have professional qualifications. The next layer, to be found immediately beneath the surface, holds values readily obtained by educated and informed persons whether medical or lay. As we burrow beneath, we find that the succeeding strata become more and more inaccessible. For them we need to dig deep and direct our toil with concentrated intelligence to find the special ore and to distinguish it from the ordinary metals. These strata are reserved for the trained and experienced expert and the present speaker will not venture to explore them. But he may safely venture, as he purposes now to do, into the strata of knowledge of mental illness where every man with medical training, should be able to find his way about. In recent years we have arrived at a degree of appreciation of the importance of prevention here as elsewhere and a juvenile conception of why and how we practitioners should "get busy."

Without an excessive degree of assurance we therefore present for your consideration the prevention of mental illness. This is the main object of what is called mental hygiene. The psychiatrists tell us it is mental hygiene. This is a comparatively new subject to most of the world. It is nevertheless now a headliner because the percentage and prevalence of well-balanced sound minds do not increase in proportion to the increase of population. Also because of the increasing burden of mental illness and the awakened interest of man in his own personality and its problems.

Its scope is immense. The elaborate problems to be solved in the best care of the mentally sick and feeble-minded belong here. Constructing more and more piles of

masonry and brick for custodial care is not the answer. Scientific prevention is the fascinating ideal. For each mentally deranged person there are a dozen in the domain between insanity and complete sanity. There are several times the sound dependable brains that there are deranged ones. In the crowd in the "land between" there is an immense quantity of mental power going to waste, perhaps for the lack of intelligent guidance and hygiene. Psychiatrists insist that a considerable proportion of our literature, art, poetry, and music is produced by psychopaths. Many moderns "measure our superiority over our ancestors by the greater luxury of our mode of living" (Strecker). Professor Einstein has said "The world has slowly grown accustomed to symptoms of moral decay. One misses the elementary reaction against injustice and for justice—that reaction which, in the long run, represents man's only protection against relapse into barbarism." The complexities of modern life are presenting mental and physical problems which affect everybody, but the mental predominate however important the physical. The personality of every individual makes a definite impression upon the world in his day. "In the last analysis, *anything*, no matter how trifling, which raises the mental hygiene of the individual is a boost for civilization, anything which lowers it is a knock" (Strecker).

Very learned, wise physicians consider that physical hygiene and mental hygiene should go hand in hand, are interdependent, and that the application of one without the other produces an incomplete or lop-sided human element with which all human elements must live and deal. How many of these deformed natures are there in proportion to people of well-proportioned development? And how many are mentally diseased? And in which half of the wide borderland are they performing? Con-

Read at the Annual Meeting of the Fifth District Branch, Louisville, September 23, 1937

template Europe—especially Spain, Germany, and Russia! Survey fifty million Frenchmen! Take a bird's-eye view of the United States of America! It seems that "the idea that reform owes its vitality to the recognition of moral principles is rejected by most of our modern so-called reformers, who see not the slightest connection between ends and means, between ideals and conduct. It is no longer considered indecent to use the most ruthless methods to assassinate the character of one's opponent. There is one conception of justice for the rich, another for the poor. Violence is justified in the hands of one group and denounced in the hands of another" (Dorothy Thompson). Of course we can judge only by the places and people we read about in a "free press." And incidentally how mentally hygienic is the "free press?"

As we attempt to "match up" physical and mental hygiene we find that they are not exactly alike any more than are the many other objects which we see going about hand-in-hand. To thoroughly appreciate their spheres of influence we must define their "unlikeness." Physical hygiene is largely material, anatomical. You cleanse the skin with soap and water. You sterilize drinking water and pasteurize milk to kill bacteria. You mask the worker-indust to prevent inhalation of flour, metallic particles, silicates and coal dust. You exercise to develop muscular power and agility. But you would not *think* to do these things without a mind! Mental hygiene is largely physiological in its approach, if we grant the existence of essential brain-cells and their dependence on the physiologic action of other anatomical parts like heart, lungs, arteries, blood, and so on. Physiology is the "science of the workings of the healthy human body" (Curtis). So when the brain cell goes to work it inspires and guides the workings of the other parts. While itself a small anatomic element dependent on others, its physiology dominates activities in many huge material parts. While readily admitting anatomic and physiologic elements in both, we believe that a clearer practical conception of mental hygiene is evolved by thinking of it as largely physiological as compared with physical hygiene largely anatomical.

Here enters the hand-in-hand business!

Physical hygiene is largely concerned in preventing certain contacts, intakes, obstructions, or injuries which will lessen the physical potentialities of bone, muscle, blood, viscera, et alios. Mental hygiene is largely concerned in preventing those contacts, intakes, obstructions or impressions, which will implant fear, hatred, abnormal pride or unreasonable sense of importance. Moreover and of greater significance it aims to prevent the collapse or delirium of protest or the deep shrinking sense of hurt which often interrupts life's progress in those crises or seeming crises with which we are all familiar by observation and personal experience. This means the development of mental qualities and powers by training, influence and cerebration, which will afford elasticity of mind and a large degree of intelligent serene accommodation to shocks and reversals and perhaps to the most delightful surprises of circumstance (For we need to learn how to adjust ourselves to prosperity as well as adversity). To give ideal results the elasticity referred to must be of coordinated mental equipments in turn coordinated with the elasticity of coordinated physical equipments. We all know that such highly coordinated elasticity is observed and experienced—but in what proportion of lives? We leave the answer to psychiatrists of long experience who possess a wealth of records.

While thinking and talking about elasticity you may sagaciously ask for an authoritative definition of elasticity, even though you all have definite conceptions of its meaning. So here it is.

"ELASTICITY That property of matter by virtue of which a body tends to return to a former or normal size, shape, or attitude after being deflected, compressed, expanded, twisted or drawn (extended), the rebounding quality of bodies, as the elasticity of the air, the bow has elasticity.

"Elasticity may be of (a) volume as when a gas is compressed—or of form as when a solid is distorted."

It so happens that the Standard Dictionary that we use in our study was published in 1913, and to give evidence that Mental Hygiene is not intrinsically a new subject we add the secondary definition of "elasticity," which is—(Mental) "The tendency to recover from depression or misfortune, buoyancy, also the capacity for adjustment or accommodations as to changed

circumstances, as the elasticity of youth"

Now we all know that this "elasticity of youth" is not always developed in youth or early maturity, because of the notorious aberrations of the youthful mind, the indifference to the responsibilities of living, the excessive development of delictious habits, and the descents into criminality. However the "elasticity of youth" is the normal, and one of our outstanding responsibilities as physicians is to maintain this intellectual quality in ourselves until the end and to so influence our people that it develops and endures in them through circumstances fair and foul.

Mechanically "elasticity" can be measured

A "modulus" is a number, coefficient, or quantity that measures a force, function or effect. Thus the "modulus" of elasticity of human muscle can be accurately measured. Most of the elasticity of the human body abides in its muscular structures, voluntary and involuntary.

In contemplating mental hygiene, the prevention of mental disease, we can reasonably liken "the elasticity of youth" mentally to the "elasticity of youth" muscularly. There is just this difference. The "elasticity of youth" will sometime be replaced in muscles by the production of fibrous tissue. Whereas mentally the "youthful resilience" may be maintained until advanced age—and is its grandest resource and solace. An eminent example of this was the late Mr. Justice Oliver Wendell Holmes, whose mental acumen and agility endured to the end. We can therefore foster the development and maintenance of "mental elasticity" as a prime duty in the training of humans from birth to old age.

There are systemic diseases which often cause important degenerative tissue changes in cerebral centers, spinal-cord and throughout the network of nerves. It goes without saying that the prevention and early conquest of these diseases constitutes mental hygiene of prime importance. Thus the developing intensive war on syphilis is an important material contribution to mental hygiene. Modern early discovery and arrest-cure of tuberculosis has illuminated many a darkened mind otherwise destined permanently for the shadows. No disease is more likely to cause the fibrosis or sclerosis of cardiovascular disease than dia-

betes. Thus the prevention of diabetes in susceptible races or families is mental hygiene, also insulin and the modern balanced diabetic diet. Thus with other systemic diseases—gout, arthritis, acute infections and various grades of chronic sepsis, also toxic substances, alcohol, lead, hypnotics, and sedatives. We must not forget trauma and gross brain disease and cerebral arterioscleroses. The beneficent influence of preventive medicine along many lines again convinces us of the "hand-in-hand" element in physical and mental hygiene which amounts to a merger.

Now where does all this lead us? Where but to a realization of the magnitude of the responsibilities settled inexorably upon leaders in the world. This means not a few Psychiatrists must lead us in the details and tactics of warfare upon mental disease and of prevention. We must learn the role of emotions and conflicts in the production of physical symptoms and complaints. The bulk of responsibility in prevention must be borne by parents, teachers, clergymen, physicians and hospital personnel (for sick bodies are usually crowned by sick minds), business executives, shop and other foremen, radio and cinema producers, authors, newspaper writers, publishers, and last but far from least all government officials, national, state and municipal who are elected to accomplish great good *for the people*. If we except ten per cent of parents, many clergymen, twenty per cent of physicians, and a scattered hospital personnel, the bulk of these responsible people are not practicing mental hygiene but its antithesis. Common attitudes toward mental illness are indifference, evasion, perplexity, or useless sometimes detrimental fussing.

In a campaign of Preventive Medicine it is incumbent upon us physicians to encourage and expand the practice of mental hygiene. Convincing addresses to medical and lay audiences whenever and wherever possible will be helpful in sounding notes that will reverberate in human welfare for decades to come. The Mental Hygiene Committee of the State Charities Aid Association is alive to the need and will help us while themselves campaigning. Our own Public Relations Bureau is ready with amazingly efficient service. Moreover every earnest psychiatrist will not only counsel with you but will himself present some phases of the subject upon which you and

I might hesitate to embark. Thus we will initiate another phase of the campaign of prevention to which our House of Delegates has pledged us. We can only start this year.

The harvest from prevention can only be reaped after a decade or more of devoted work.

Along with our Helen Wills', Eleanor

Holms, our Lou Gehrigs and Joe Louis' and other models of physical development, let us aim and work to develop more of the Jane Adams', the Mary E. Wooleys, the Parkes Cadmans', the William Lyon Phelps', and the Oliver Wendell Holmes' and, let us not forget, more William Oslers. This illustrates our conception of the objectives of Mental Hygiene.

Presidential Greeting to the Oswego County Medical Society

On the evening of the One Hundred and Sixteenth Anniversary of your County Society it is well to review with pride the composite advance of the years, and to contrast the size and scientific activities of the first meeting of members with the dimensions and evidence of vitality presented tonight. However, the most important business of your Anniversary Celebration is to look forward and determine what shall be the ideals and objectives of the next one hundred and sixteen years more or less. That we are constantly striving to develop and expand our quality and capacity as physicians goes without saying. We often remind one another that scientific work is so fascinating and human needs so absorbing that we sometimes forget that our part upon life's stage is a dual one, and omit to fulfill all of our duties as citizens of the State, Nation and the wide, wide world.

A County Society can competently keep efficient citizenship before its members as a constant ideal. Activities along the line of postgraduate medical education are inspiring self-liquidating efforts for a County Society—of priceless value to the community. Close association and cooperation with the Health Officer and the Department of Health smooths the track of medical progress. Wherever we have found local Health Officers integrated with the official and committee work of a County Society we have found harmony and efficiency. Every physician should be a deputy Health Officer in spirit and in fact.

Closer cooperation with the State Medical Societies and the great American Medical Association will advance the largely needed effort being made by so many of us to secure unified thought and action. Our

socialistic enemies gaily play upon our widely published differing opinions about the *very little* details of practice, while we actually agree upon the principles and main issues concerning the delivery of Medical Service.

We can safely express our unified opinion through our State Society Bureau of Public Relations or through the great editorial offices of the American Medical Association. Individual or even independent group opinions are often based upon incomplete or inadequate information, whereas the headquarters, which you all help to maintain, has the machinery for collecting and weighing all evidence and considerately presenting unified opinion.

Scientifically, in addition to lectures and demonstrations on postgraduate education your State Society is endeavoring to popularize and develop the practice of Preventive Medicine (as a practical answer to those who talk about inadequate medical service). Active efforts to universalize scientific immunization protection in known fields is, of course, primarily in order. The pivot about which revolves the balance of preventive medicine is the periodic health examination. County Societies can provide speakers to expound the advantages of this measure, to lay audiences. Specific problems in prevention, such as tuberculosis, cardiovascular disease, wound infections, and a hundred others can also be presented. We suggest *specific* problems. Of what practical value are generalizations? One by one outstanding examples can be discussed with the hope that the massing of evidence along an extensive front battle line will sometime render obsolete the desire to cure or be cured of an *advanced* disease, because

of a universal desire to anticipate such occurrences

We can look forward to the day when there will be many specialists in periodic Health Examinations who work alone or in groups

Done with complete and conscientious competence it will prove to be valuable insurance for the people and a delightful, profitable practice for physicians. But people and physicians must develop a

new light upon the value of life—of time and of prevention. And we must be well prepared in preventive medicine to practice it successfully. So as we felicitate you upon your birthday we invite you to our Prevention Party. If you and all of the other invited guests keep at it for the next one hundred and sixteen years there will be a change in the character of illness seen, a prosperous and revered profession, and a general expansion of well-being.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., DR. PH., New York City

Editorial Note: Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

A Condensed Reply to a Psychoneurotic

(Abbreviated summary of several talks)

"You have asked me to be frank and I shall not spare you. In the last few sessions you have been speaking all that you desired. If you will keep quiet now I shall have something to say. You talk so fast and so well because you try to convince, not only the doctor, but yourself. Deep down you are not entirely certain about your complaints. You are doing all you can to hold on and not to let anyone cure you of them because you need them. I know, you will say that, on the contrary, you have gone to doctors and have tried your best to effect a healing, but there was no success. The truth is you have done all that in order to be able to say to yourself and to others that your ailments were incurable. In the first place, it is quite doubtful whether there was anything physical to treat and no matter what would have been accomplished it is certain that you would not have accepted it as a cure. You are sure you cannot exist without your pains and aches because they cover up your real conflict, which is not hidden from you and of which you are perfectly aware: your hatred for your husband and your lack of courage to separate from him. Besides, your suffering is connected with some pleasure. You enjoy your trouble because it is the only thing which distinguishes you from other people and which helps you to attract attention to yourself. It is your beloved subject of conversation and it gives you an excuse for acting, for posing, for being interesting, although you are mistaken about that, as you are really a bore to everybody concerned. If you were an advanced psychoneurotic it

would be useless to tell you all these things. You would not even listen, being preoccupied with your condition. But you are not. You can still be cured. That is why I have consented to give you advice. No matter how selfish you are, no matter how little you are concerned about anything outside yourself, no matter how much contentment you derive from constantly thinking and speaking about yourself, you are unhappy. Your problem is not solved and your eternal whining and complaining will not solve it. You are over forty and, while you can live another thirty years or so, your life will continue to be miserable. The pity of it is that we know perfectly well that you can be happy or much happier than you are at present for the rest of your existence, if you only desire it, if you are capable of desiring it—and I claim that you are.

You are not only harming yourself, but you are doing untold harm to others, to your nearest kin chiefly. Perhaps you really "do not give a damn," as you say, about the fate of any one else in your family. But if you are aware that you are hurting your own children and are doing so the more intentionally, you are a despicable person. You would do better to desert them altogether, to disappear from their presence, so that they should never see you. What would you think of a woman who would deliberately infect her children with syphilis? How would you judge a tuberculous person who would purposely disobey all hygienic instructions in order to have her children catch consumption? Well, your

actions are worse, much worse than that. Your incessant if monotonous repetition of your complaints before your two helpless little girls, the only creatures who are forced to listen to you, your invariable wry face, your endless threats of suicide, your laziness and frequent excuses of sickness in order to shirk your duties, are a bad poison for them, for their minds. They have already started on the fatal path. They have begun to imitate you. But they can still be saved. They are bound hands and feet and exposed to your mental venom. If you will not change your behavior it is almost a fatality that they should suffer from some disease of the mind and perhaps of a worse condition than yours. If they will understand the source, they will hate you and curse you in their horrible semi-lucid moments—and you will have deserved it. And not only that. If they have children, they will transmit some insanity to them, not by heredity, but by holding before them a mirror, by their bad influence, by their obnoxious suggestion in the same way as you are forcing now your children to become mentally ill.

"For years you have been complaining about a vague ache of the left side of the face, extending to the left shoulder and the left arm. All the honest physicians who have seen you have told you that nothing abnormal was found. Your descriptions and indications corresponded to none of the diseases or symptoms of diseases which we encounter in those regions. Through certain scientific methods, with which experienced doctors are familiar, it was discovered that you had no pain whatever. This might have been interpreted as malingering. However, it really did not mean that you were simulating, but that your mental state forced you to lie. Had no physician treated you at all, perhaps you would have been better off. But they were not a match for you. While they were well-informed about the human body, they knew but little about the mind. They were timid and you have done all you could to make them doubt and lose confidence in their own convictions.

"Further, not satisfied with their verdict, you went on searching, until you fell into the hands of less scrupulous men, officially condemned by the profession. They seized upon your disorder, took advantage of your misfortune, making believe that they were treating you. There was mutual deception. You thought you fooled them and they were sure they deceived you. Some very meaner and more cruel than others. They had your good, healthy teeth extract and they extracted your husband's money by giving you unnecessary subcutaneous or intrav-

enous injections and treating you with electricity—and so on and so forth.

"Then you descended to the irregular healers and to other swindlers and you let them work upon you. The more they handled you the more you liked it, although at no time were you either helped or satisfied or happy. Not that you believed in them. No, you knew before you started that you would not respond. Your mind had been made up in advance.

"Later you discovered psychoanalysis. You allowed your personality to be taken apart, as it were, but you resisted all you could to a cure and when you believed there was danger of improving your trouble or getting rid of it, you quit your examiner without coming to a conclusion.

"Finally you visited the lowest quacks, the Negress who sweated you in blankets, the mysterious, turbaned and bearded Hindu who reincarnated you and the Great Spread-Winged Eagle who purported to be a descendant of a Red-Skinned Chief and who gave you a herb and a written prayer.

"You are living with your husband although you cannot stand him. He is nice to you. In fact he is an angel, gentle and submissive, while you are the dominating figure in the house if you only cared to rule. You are not interested in any other man—or woman. Your husband is faithful to you—and, as far as you are concerned, you would prefer him to be otherwise. He is not forcing the sexual intercourse upon you. You desire it rarely, at least with him, and each time you have it, you make it appear as if you never craved it but that you sacrificed yourself to save him. You also make him pay for it by abusing him for his so-called brutality. An August Strindberg, after seeing you, would find in you a worse fiend than he could have ever imagined and his misogyny would soar more triumphantly than ever. Of course, it is your right to detest your husband. But then, why don't you leave him? You have no income, your parents are dead, you have never worked for a living. That is no excuse. A proud, brave person would defy all that and would become economically independent. You used to have so many abilities. You can revive them. You have had a high education. You are cultured and intelligent. What are you doing with these qualities, so harmful in your case? You are using them as tools to make your condition worse, as weapons to fight off any possibility of a cure or any hope for an amelioration.

"But if you live with your husband, why don't you make peace with him? He has never ceased to hold out the olive branch to you. You have ruined his life partly,

but your tactics have acted like a boomerang and you have wrecked your own life, so far, completely. You can still save the situation. An effort to readjust yourself is still possible.

"I know, you have read—or rather skimmed, since you have no patience to read—books on psychology, on psychoanalysis and psychiatry and you were happy to learn that you were not supposed to have the will-power to do anything definite, that your personality was disintegrating and nothing can be expected of you. Disabuse yourself! Your mental disorder has not gone far and it fails to fit the descriptions of the learned authors.

"Would you really wish to become insane? To be shoved aside, shelved and locked away, to talk nonsense for a year or for lifetime? Is it a good thing? I assure you, it is still within yourself to avoid it, to prevent it.

"You have been toying with the idea of committing suicide. You have scared your people many times. Your meanness, your cruelty is so great that you are enjoying the Damocles sword over their heads. For them it would be preferable that you should lay hands on yourself. For you, too, if you are not going to discontinue behaving as you do. But you have been lying. You have never even attempted to kill yourself. And, since you are alive, why don't you live decently? Why don't you make a good and efficient job of living? As you are not dying, why not agree frankly and honestly to live and to live fully? Your suicidal hypocrisy cannot help you.

"And what about life? If you despised it on principle or on philosophical grounds, I would have no objection. But you do not. Just now you are on bad terms with the world that surrounds you. But you can appreciate the world's beauty, you know

where to find it and you have the means to enjoy it.

"Now you have come to see me. Unless you run away never to return to my office, I shall not flatter or coddle you, or help you to become spoiled or to nurse and perpetuate your condition. A physician should be medically non-sectarian and should make use of all possible methods by which he can save life and limb and the mind. I would not object even to magic if I knew that it could be useful. But it cannot. You have heard that we are supposed to be less severe, that we cannot ask you to get well when you are not. That is perfectly true in other cases, in bad cases. But I cannot leave you even this subterfuge. You do not belong there and I must 'treat you rough,' as you say, which really means being honest with you. And this for your own sake. In many cases like yours and particularly in those we used to call hysteria the cure often employed, especially by the French school is drastic and quite cruel, as, for instance, a very strong electric current, pushed almost to the limit of endurance. It works, it shows effects, often immediate and brilliant, but, alas, very temporary ones. My harshness will either be useless or it will heal you completely and permanently."

These talks had their effect in this case. After a lapse of several weeks this patient came back and said:

"Nobody has been so outspoken with me as you. It was hard to follow you. Sometimes I felt like slapping you. But your words were not wasted. They were too compelling. I have digested every one of them. I thought matters over and here I am to tell you that I am on the road to recovery."

AMERICAN MEDICAL GOLFING ASSOCIATION

A "Golfers Special" to the San Francisco meeting of the A M A is being organized by the American Medical Golfing Association. Physicians who like golf mixed with their travel will find five games arranged on their trip out to the coast for the A M A meeting of June 13-17, 1938, and three games on the return trip through the Northwest. The first game will be played in New Orleans, reached by the Steamship S S Dixie, from New York (or via a rail itinerary) on June 7. Other stops include Houston, Galveston, San Antonio, Los Angeles, Del

Monte, and finally San Francisco where the big tourney will be held June 13.

The return trip includes Portland, Seattle, Vancouver, Lake Louise and Banff, and finally St. Paul and Chicago.

Non-golfers as well as golfers, and their ladies, are welcome and will find the A M G A Special a glorious experience.

For full particulars write Dr. Walt P. Conaway, 1723 Pacific Avenue, Atlantic City, N. J., the President of the A M G A, or Bill Burns, Executive Secretary, 2020 Olds Tower, Lansing, Mich.

EDITORIALS

Pertinent Criticisms

Like Sweden, Czechoslovakia has often been cited as a model for social legislation. Yet in less than twenty years so many faults have revealed themselves in her "model" system that widespread revision is now under consideration.

In connection with contemplated changes, it is interesting to note a statement issued jointly by the Czechoslovakian and German Medical associations, for the situation of which they complain exists today in this country to an unprecedented degree. Referring to proposed amendments to the insurance law, our German and Czechoslovakian colleagues make the following pertinent observations:

"The medical profession certainly has a right to be heard regarding all these measures, which so deeply affect the professional, economic and social interests of medicine. In spite of this fact the physicians have been given no opportunity to present their suggestions or to express their needs and their desires with regard to this proposed legislation, except that here and there they have been permitted to express their opinion on a few points.

"The profession has been given no opportunity during the preparation of

these laws to contribute its medical experience and knowledge. We do not know just why the value of medical cooperation has been so little recognized or why it has gained the distrust of social-political circles, both official and nonofficial, nevertheless it is evident that this attitude has arisen and prevails at the present time. It is clear that the profession will not at this time be called on in the preliminary stages of social work or, at the best, it will be given only a formal recognition after much insistence on its part."

In this country medicine is faced with exactly the same attitude on the part of politicians and lay social workers who enjoy their confidence. The latter formulate important medical and quasi-medical policies, and the profession is then given the choice of playing alone or being left out in the cold.

Apparently the political powers-that-be recognize that the private practitioner will never be a pliable tool in their hands and that private medical practice does not lend itself easily to political exploitation. The solution, from their point of view, is to abolish medical independence by bringing medical practice under bureaucratic control.

A superficially altruistic scheme is hatched, floods of propaganda are unloosed until a semblance of popular demand is created, and then the physician is invited either to assent or starve.

Undoubtedly there is need for wider and more effective public health planning in this country. No less here than in Czechoslovakia, however, it is necessary "that the position of the physicians should be considered in the very beginning of the discussion of such legislation and that the carefully considered conclusions and proposals of the physicians should not be disregarded."

the attitude of the profession is not in opposition to the social necessities of any citizen, but rather it is based on the conviction that the attainment of any such objectives must not sacrifice the scientific and economic independence of the medical profession."

Good Use for a Fine Word

"Together is the grandest word in the English language," said Theodore Roosevelt. When Dr. Charles H. Goodrich quoted this in urging closer medicodental cooperation, he put a grand word to good use.

The diagnostic and therapeutic facilities now available to medicine and dentistry make close collaboration between the two professions entirely feasible. With the best intentions in the world, the physicians and dentists of fifty years ago had not the scientific wherewithal to work together. Today almost every new discovery tightens the relationship between medicine and dentistry. In Rushing's words, "the human body is a complete organism with the function of each part dependent on that of others."

Dietary research, in particular, has done a great deal to bring the two professions together. The importance of nutrition, both to general health and

to the healthy development and preservation of the teeth, is increasingly manifest. From the viewpoint of prevention, the dentist who prescribes a wholesome diet for the sake of the teeth helps diminish the incidence of deficiency diseases, just as the physician who prescribes a sound prenatal diet for the mother lays the foundation for healthy teeth in the child. So the dentist who discovers a focal infection in the tonsils or sinuses in the course of his examination renders another important service to medicine, paralleled when the physician's search for a focal infection uncovers disease or irregularities in the teeth.

Obviously the teeth, which play so large a role in health, cannot be dissociated from the rest of the body. The dentist and the physician must work together, for the fullest development of their respective professions as well as the welfare of their patients.

The possibilities of such collaboration have as yet barely been grazed. More frequent joint scientific sessions would suggest fruitful avenues of cooperation. So would the merging of medical and dental libraries—or reciprocal exchange of privileges—to enable the members of both professions to keep abreast of advances of mutual interest.

Prevention of Mental Illness

It becomes increasingly difficult to editorialize upon our President's addresses, yet the duty to do so devolves upon us. His address before the Fifth District Branch meeting on "Prevention of Mental Illness" must be read in the original to be fully appreciated (see page 2036). He notes the increase of unstable minds over healthy ones in proportion to the increase of the population, and stresses remedies to correct this.

We are intrigued by his statement that "a considerable proportion of our

literature, art, poetry and music are produced by psychopaths" Perhaps it is necessary to have this type of mind to produce these expressions of what is called "art," but even when produced by psychopaths, civilized man thoroughly enjoys the products of such mentality! If by curing these psychoses posterity were deprived of this literature, poetry, art, and music—would not our civilization be much poorer, exceedingly more drear and drab, and the incentive to provocative thought perhaps less?

Looking at this particular angle of the question from the commentator's standpoint we cannot deny that while we enjoy all that is implied in this art, read with avidity its literature, enjoy its poetry, have our senses bathed in the glamor of its music, or stand entranced before a statue or a painting—how happy we are that we do not have to live in close contact with the artist. The stress and struggle of daily life with one of these psychopaths is quite another matter. Of course, Dr. Goodrich is dealing by and large with the question of mental illness among so-called average people. We are indebted to him for having called attention to a field in preventive medicine too often not encompassed in programs of preventive medicine, and he deserves well of us for his masterly handling of a difficult topic

Tuberculosis Among Negroes

The National Tuberculosis Association recently has released an illuminating report¹ which merits the serious consideration of the medical profession and all others interested in the promotion of our national health. While priding ourselves upon the success achieved in our campaign against the ravages of

tuberculosis, we inadvertently have permitted an important phase of the problem to be relegated to the background.

The Association designated a committee to study and investigate the causes underlying the high mortality rate from tuberculosis which prevails among our negro population. Five years of intensive research are summarized in the published report of the Committee. Negroes in the United States constitute approximately ten per cent of our population. Nevertheless tuberculosis, seventh in rank as a cause of death among whites, is the second most important factor in the mortality statistics of negroes. Quoting from the report, "the tuberculosis mortality among the colored population now stands, in fact, at a level around which the white mortality hovered twenty-five years ago."

Northerners will receive a shock from the Committee's observation that in the southern states "the most recent data shows a much lower mortality among the colored population—less than three times that of the white population." Tuberculosis as a cause of death in the negroes of our southern states definitely has been on the decline. The reason for the continuing high mortality rate from tuberculosis among negroes must therefore be sought in the tendency of our colored citizens to migrate to, and concentrate in, urban communities. Unfortunately, the great mass of our negro populace shows no interest in the active prevention of a disease which reaps the greatest harvest from its own ranks.

Negro leadership is needed in the fight against tuberculosis. Negroes and whites are closely associated in their daily tasks and any program for the control of tuberculosis is a vital concern of both. "The Committee feels that it is impossible to over-emphasize the importance of cultivating the right kind of negro leadership." With such cooperation "one of the weakest salients in the fight against tuberculosis" will soon disappear.

¹ A Five Year Study of Tuberculosis Among Negroes, Nat. Tbc. Ass'n 1937

Scope of Insulin Therapy

Originally hailed as the remedial therapy for diabetes mellitus, insulin has been employed within the past few years, as a therapeutic measure for many pathologic conditions far remote from that which produces the clinical picture of the deficiency disease for which its use was primarily intended¹. The extension of insulin therapy to include nondiabetic conditions merits particular notice since its use in this direction is not founded upon any sound pharmacological or physiological principles. From a purely empirical basis, cardiac, pulmonary, and renal disorders have been treated with insulin and investigators report that a decided therapeutic result is evident in all of these conditions. This favorable comment holds true also for other diseases among which are included gastrointestinal, menstrual, and allergic disorders. In the limelight at present, is the remarkable effect of insulin in the treatment of certain schizophrenic states.

Since many of the abnormalities for which insulin is being administered respond exceedingly well to other therapeutic measures, the sole use of this hormone as a therapeutic agent must remain open to question. The individual case report tells us nothing. A large series of observations, however, repeatedly recorded by independent workers, must be given consideration. It is known that a mild hypoglycemia stimulates the appetite and counteracts anorexia. In pulmonary tuberculosis Spellberg and Rosenblum² found that insulin therapy enhanced gastric motility and stabilized glycogen metabolism. Consequently such disorders which are associated with a loss in body weight should be benefited by the judicious use of insulin.

Simple undernutrition and pulmonary phthisis, at this time, must be considered

as the primary indications for the extradiabetic employment of insulin. While not a cure, its use induces hunger and so, indirectly, leads to an increase in weight. In the treatment of psychoses, despite the encouraging reports which have appeared in the literature, insulin therapy must still be relegated to a select few until such time as means for its use will have become standardized. Meanwhile, the study of the therapeutic indications of insulin should be continued. One has but to remember quinine and mercury to appreciate that the empiric of today may become the specific of tomorrow.

CURRENT COMMENT

"IN WASHINGTON, D C, WHERE GOVERNMENT employees far outnumber all other employed groups, the philosophy of regimentation, socialization and arbitrary control of everybody's business might well be expected to satisfy thousands who owe their employment to bureaucracy raised to the nth degree. Running true to form 'A Cooperative,' organized among the 117,000 Federal employees located in the nation's capital city, which is governed by a committee of Congress, has recently begun to experiment with a socialized form of medical practice made available to its membership. The benefits paid for by a monthly pay envelope deduction will include the ordinary 21-day hospitalization accommodations and the preventive, as well as the curative, professional medical and surgical services of a group of physicians.

"Probably the crowning impertinence of this 'opening wedge' lies in the statement made by the management of the cooperative to the effect that no physician thus contracting for the disposal of his services may be excluded from the medical societies of the District of Columbia. This is certainly a disquieting and discomfiting demonstration of the ends to which so-called new-deal experiments may go in the conversion of private physicians willy-nilly into Federal officers and private medical practice into a *new* health system.

"How can the organized medical profession continue to discharge its obligation to apply universally the scientific stores of knowledge reflected in medical progress if its ethical codes are to be swept aside

¹ Therapeutics, *Am J Sci* 194 727, 1937
² Spellberg, M A and Rosenblum, S H *Am Rec Tbc*, 34 376, 1936

by politically-minded zealots?"—*The Pittsburgh Medical Bulletin* warns us of possible "Wedging In," and is quoted in the *St. Louis County Medical Society Bulletin* of November 5

"JUST AS THE WHILOM DANCING marsh light has ever lured the curious deeper and farther into the bog, so the pursuit of a definition of 'adequate medical care' may lead—if not into the quicksands—quite possibly into the madhouse

'The phrase has assumed all the supposed virtues of the philosopher's stone, while not thereby losing in the least the fantastic, elusive, quality of its lure. Adequate medical care now you see it, now you don't, but it must be somewhere, it must mean something! If only it could be captured, defined, it, like the philosopher's stone, could transmute the dross of poverty and misery into the pure gold that strangled Midas. But alas! Pursuit is seemingly endless, leading ever deeper into the gloomy morasses, into the how-muchness of the enough'—"*Ignis Fatuus*" states the *Westchester Medical Bulletin* of November, in the foregoing editorial

" IT IS NOT SURPRISING THAT popular opinion is being constantly misled and confounded. All the while from press pulpit and microphone, it is being fed by half-truths that conceal material facts. Propaganda is at once the principal weapon and curse of our age. It is the result largely of overspecialization of a

world, in short, that has lost its sense of general standards

"Everybody has his own pet panacea to advance to the exclusion of everyone else's. And to advocate them, nearly everybody exaggerates and distorts facts till the public is like a blind man trying to find his bearings in a room in which everything keeps moving."—Arthur Bryant tells of "The Curse of Propaganda" in *The Observer*, an English publication recently quoted in *The Digest*

"CAN AND WILL PRIVATE PRACTITIONERS take their rightful places in school health work? The answer, of course, lies with physicians and dentists themselves. In order to accomplish this objective they must make the families under their care conscious of the value of medicine. They must demonstrate conclusively that they are equally interested in the prevention as well as the cure of disease. They must counsel and advise school authorities, working with them in close harmony

"School health work is developing rapidly and is becoming more standardized because of the impetus given it recently by the United States Public Health Service and it seems to me that an opportunity is immediately at hand for the family physician. Unless he takes advantage of it he may find that at least this phase of public health activity has been lost to him."—Dr. Jerome M. Jekel writing on "The Family Physician and School Health Work" in the *Supplement* to the *Saint Louis County Medical Society* for October

THE DOCTOR'S RISKY LIFE

Adventures in the jungles or on mountain peaks have nothing on the doctor in the way of facing danger

Press reports from France tell of the fourteenth operation performed on Professor Charles Vaillant as the result of his experiments with x-ray. The professor does not think his sacrifice remarkable, according to *The New York Times*. Valiant is the word for Vaillant!

The history of medicine is particularly rich in the noble martyrdom which forswears health and life itself to bring these blessings in greater measure to the rest of the race, remarks the *New York Medical Week*. In the U. S. Public Health Service alone there are seventeen names on the honor roll of those who defied death in the

line of duty—and lost. Independent research and private practice swell the list of medical martyrs to much greater length

Not all the heroes of medicine get into the papers and people are inclined to forget the risks that even ordinary medical practice entails. Influenza, typhoid, tuberculosis are routine hazards. The high percentage of practitioners who die at an early age from heart disease testifies that even when a physician escapes dangerous contagion he pays the toll of exposure to all sorts of weather, insufficient and interrupted rest and, worst of all, constant responsibility

Contrary to the belief of those who think that all a doctor has to do is write a prescription and collect his fee, the practice of medicine is no "snap"

THE WOMAN'S AUXILIARY

To the Medical Society of the State of New York

KINGS COUNTY The Woman's Auxiliary of the Medical Society of the County of Kings met at the county society building on November 9. The speaker was Dr Siegfried Block. Mrs Edwin A Griffin presided, and Mrs W Reynolds Shetterly was hostess. Dr Thomas A McGoldrick, President of the County Medical Society, was presented with a check from the Auxiliary for the Kings County Library.

ORANGE COUNTY The regular monthly meeting of the Woman's Auxiliary to the Orange County Medical Society met at the Interpines, Goshen, on November 9.

Miss Helen Watkins, Executive Secretary of the Orange County Health Association, was the guest speaker. She gave a resume of the work the Society is sponsoring in educating the public in the knowledge of cancer.

On November 16, the Health Association held a meeting of the women of Orange County to hear Dr Louis Kress, Assistant Director of the Institution for the study of Malignant Diseases, speak on "Cancer in Women."

QUEENS COUNTY At the October meeting of the Woman's Auxiliary of Queens

County, with Mrs John W Mahoney presiding, Mrs Greenspan read a review of "The Citadel," by Dr A. J. Cronin. Mrs. H. P. Mencken, chairman of the committee on revisions, brought in many important changes in the by-laws. These changes were voted on and accepted by the Auxiliary. Mrs Frank Dealy, chairman of the nominating committee, announced the slate as follows: Mrs William Lavelle, *president*, Mrs D. J. Swan, *vice president*, Mrs Sam Klein, *recording secretary*, Mrs J. Kilcourse, *treasurer*, Mrs William Godfrey, *assistant treasurer*, Mrs Thomas d'Angelo, *historian*.

ROCKLAND COUNTY The Woman's Auxiliary to the Medical Society of the County of Rockland held their first meeting of the year on October 13, at the Summit Park Recreation Hall.

SARATOGA COUNTY The December meeting of the Woman's Auxiliary of Saratoga County will be the annual election of officers and will be held with Mrs Edward J. Callahan of Schuylerville, as hostess. This will take the form of a Christmas party to which the County Medical Society has been invited.

PERILS OF OUR BEAUTY MAD GENERATION

Manufacture of new products involving risks to the consumer or the factory worker should be subject to acceptance of public health authorities before they are produced and put on the market, Dr Haven Emerson, director of public health in the College of Physicians and Surgeons, declared on Oct 20 in Columbia University's McMillin Theatre, where he delivered the memorial lecture celebrating the 100th birthday of Dr Charles Chandler, noted chemist.

"Almost daily," Dr Emerson said, "some new and secret-formula product is offered for human use and consumption, untested biologically before commercial exploitation and used widely by the ever-gullible public, avid for novelty, convenience or apparent profit, until some unsuspected but irremediable damage to the consumer has developed to warn physicians and sanitarians of a new problem in diagnosis, treatment and prevention."

The danger of poisonous cosmetics, investigated by Dr Chandler more than sixty years ago, is a problem still holding the health officer "at the mercy of the consuming public, which expects protection even in its silliness," Dr Emerson said.

"As one looks about at the cadaveric finger-tips, the enameled toe-nails, the deformed eyebrows, the filled facial creases that try to reveal character but are cheated out of it, the hectic cheek reminiscent of the fever ward of a tuberculosis hospital, the ill-assorted daubs of aniline upon the lips," he observed, "one wonders if it is worth the while of Congress to try to enact protective legislation, or health officers and their laboratories to attempt enforcement of local ordinances to save a beauty-mad generation from those qualities of cosmetics that threaten to replace the bloom of health with one more appropriate to a dish of wax fruit."

Public Health News

A four-minute trailer with sound, on the treatment and prevention of diphtheria has recently been prepared by the division of public health Education of the State Department of Health. The treatment is historical and traces the treatment and prevention of this disease from the discovery of the causative organism to the present day. The wholehearted acceptance accorded to this trailer by the picture theaters of Albany suggests that, with the

use of accompanying music and voice on the thirty-five-mm film, health educators have reasserted themselves in the commercial field of visual education.

A sound trailer adapted from the silent movie "Story of My Life by Tee Bee" is also available from the Division of Public Health Education, State Department of Health. Other trailers are being planned. Suggestions from the medical profession will be welcomed.

PNEUMONIA CONTROL PROGRAM

Plans for the fall pneumonia control work were discussed by Dr Edward S Rogers and Dr Harold W Lyall at a meeting of District State Health Officers held at Albany on November 8. Dr Rogers pointed out that at the present time only one-third of pneumonia patients who are hospitalized are having blood cultures. Since a blood culture not only produces valuable checks on typing but also is of importance in estimating the seriousness of infection and determining the direction and intensity of specific treatment, he urged that the method should be used more frequently. A blood culture may provide information concerning the incitant, when more than one type of pneumococcus has been found in a specimen of sputum.

District State Health Officers were requested to notify the Bureau of Pneumonia Control immediately whenever an epidemic outbreak of pneumonia appears. Careful observation of a large number of such outbreaks is needed in order that methods of epidemiological control may be devised. It is also important that the Central Office should know as soon as an infection with a type other than I or II becomes prevalent so that serum specific for that type may be concentrated in the area affected.

An outline has been prepared for the use of medical speakers bureaus. This outline is not intended to standardize the

doctor's presentation of the subject but only to provide a uniform background of information for medical speakers. Another mimeographed outline which is available describes "A Technique of Serum Administration."

Dr Lyall informed the district officers that sera for types V, VII, and VIII are now available in addition to the sera for types I and II. The most recent sera have been distributed to twenty-four centers from which it is believed any part of the State can receive them at short notice. Dr Lyall emphasized that sera should in no case be used without preliminary typing. With the number of therapeutic sera available, it is obvious that this is essential. The sera of types V, VII, and VIII are concentrated and distributed in packages containing twenty cc. They are standardized in comparison with control sera. No unit values for sera other than types I and II have as yet been officially established. Four packages is the dose suggested for the treatment of an average case. Laboratories approved for pneumococcus typing will be provided with sera of all types for which therapeutic sera are available. While production of therapeutic rabbit serum has been undertaken, its preparation, standardization, and clinical use are still considered in the early experimental stage, and distribution will not be commenced until adequate data are available.

A man from Galway had come over to London to consult a famous specialist. "I should like to know," said the doctor in the course of his questioning, "whether your family has been what one might call a long-lived one?"

"My family," came the reply, "is a West of Ireland one, and if you know that part of the country you will realize that the age of my ancestors has always depended entirely on the judge and jury who tried them."

Medical News

Bronx County

DR EMIL KOFFLER delivered his inaugural address as president at the meeting of the Bronx County Medical Society at Burnside Manor on Oct 20 Other topics and speakers were "Preventive Medicine," Charles H Goodrich, M D, "Future of Medical Practice," Samuel Kopetzky, M D, "American Medicine at the Crossroads," Nathan B Van Etten, M D

Broome County

DR J WORDEN KANE read an interesting paper on "Neuro-Surgical Problems with Case Presentations" at the meeting of the Broome County Medical Society in Binghamton on Nov 9 Discussion was opened by Dr Charles D Squires and Dr Louis J Bragman Resolutions were adopted on the death of Dr Sylvanus J Nunn and the retirement of Dr Charles H Cole after sixteen years as superintendent of the Broome County Tuberculosis Hospital The following names were read as Speakers on Pneumonia to the Speakers Bureau Drs B A Buell, E R Dickson, H W Davis, R C Bates, S P Carlucci, Mable Martin, Harvey Smith, John W P Love, and Vesta M Rogers The following have been appointed to the Bureau as Speakers on Cancer Dr Frank M Dyer, Dr Mary Ross, and Dr Victor W Bergstrom—*Reported by Victor W Bergstrom, Secy*

Cattaraugus County

AT THE MEETING of the Cattaraugus County Medical Society held at Olean on Oct. 26, a committee was appointed in each community in the county to speak on "Cancer and Its Prevention," before any organization desiring information The Hospital Service Corporation Plan was explained by Carl M Metzger of Buffalo and after discussion the society moved to endorse the plan of the Hospital Service Corporation of Western New York

Cayuga County

A BUREAU of Maternal, Infant, Child Hygiene has been established in Auburn in cooperation with the Medical Society of the County of Cayuga As a part of this program a refresher course in obstetrics has been conducted This course was arranged by the Council Committee on Medical Education

DR RAYMOND C ALMY was elected Coroner for Cayuga County to succeed Dr Frank L DeFurio who had been appointed Acting Coroner upon the death of Dr Alfred Hodgman

Cortland County

AT THE MEETING OF THE Cortland County Medical Society held in Cortland, October 15, Dr George M Mackenzie lectured on "The Diagnosis, Treatment and Prognosis of Bacteremia" The talk was illustrated by numerous slides prepared from the results of studies made at the Mary Imogene Bassett Hospital

Delaware County

THE DELAWARE COUNTY TUBERCULOSIS and Public Health association, in cooperation with the County Medical Society, held a social hygiene dinner meeting at Walton, Oct. 18 Dr Wm A Brumfield, director of the social hygiene bureau, of the New York state department of health, was the principal speaker, with a showing of the talking film, "For All Our Sakes"

Dutchess County

DR ROBERT E FISHER of the medical examiner's staff in New York city spoke on "Sudden Death" at a postponed meeting of the Dutchess County Medical Society in Poughkeepsie on Oct. 27 The meeting was originally scheduled for Oct 13 but was postponed because of the city's 250th anniversary celebration

Fulton County

A MEETING OF THE Medical Society of Fulton County was held in Johnstown, with thirty members attending, on Oct 21

A feature of the session was the presentation by Dr William M Cooper of a film entitled "High Ligation and Injection Therapy of Varicose Veins"

Kings County

"EPILEPSY" WAS THE TOPIC of the scientific session at the meeting of the Medical Society of the County of Kings on Oct 19 The subjects and speakers were "A Consideration of Etiologic Factors and Diag-

nostic Procedures," E. Jefferson Browder, MD, F.A.C.S. and "Surgical Excision of Epileptogenous Zones in the Brain," Russell Meyers, MD

Madison County

THE AUXILIARY OF THE MADISON County Medical Society held a dinner meeting at the Hotel Oneida in Oneida on Oct 14 and elected officers

Monroe County

MEDICINE IN ITS INCESSANT war against infantile paralysis is winning in one sector—it is diminishing the effects of the disease

So Dr James P Leake, medical director of the U S Public Health Service, Washington, told 200 members of the Medical Society of the County of Monroe on Oct 25 in the first of five post graduate lectures at the society's Prince Street home in Rochester. He spoke on "Poliomyelitis," on which he is an international authority

"We hope through public health measures," he stated, "to diminish its intensity, and particularly to diminish its effect. A great many children are taken ill but few are permanently crippled"

Despite lack of a sure cure, Dr Leake stated, there is no reason for widespread pessimism

"We are going to have poliomyelitis with us," he said. "I do not see an absolute preventative, but the severe deformities are not now present."

Parents were advised to summon a physician early if they have fears about their children. Complete rest and relaxation was prescribed. He advised against massage

In general, Dr Leake said, closing of schools is not necessary although decision must depend on local conditions. Isolation of children also was not approved, in the main, except during a severe epidemic. He advised against strenuous exercise and recommended that children be kept "up to par" physically

New York County

DR. JOHN HOWARD NORTHROP, member of the Rockefeller Institute for Medical Research, received the Charles Frederick Chandler Medal of Columbia University in Horace Mann Auditorium, Broadway and 120th Street on Oct 27

After the presentation of the medal for "fundamental discoveries concerning bacteria, the constitution of proteins, and the chemistry of digestion," Dr Northrop delivered the fourth Chandler Memorial lec-

ture, in which he described his researches at the Rockefeller Institute's department of animal and plant pathology at Princeton, N J

Dr Northrop, who is the sixteenth scientist to receive the medal since it was established in 1910, was the first to isolate the digestive enzymes, pepsin, and trypsin. He also succeeded in isolating a nucleoprotein which has the properties of bacteriophage, a living organism capable of dissolving bacteria. His research made it possible for Dr W M Stanley, of the Rockefeller Institute, to isolate in crystalline form the virus for the tobacco mosaic disease, which may have far-reaching significance in understanding diseases due to different viruses

Dr Northrop was born in Yonkers on July 5, 1891. He was the great-grandson of Frederick Christian Havemeyer in whose memory Columbia's Havemeyer Hall with its chemical laboratories and lecture rooms was built.

DR. SIGMUND POLLITZER, dermatologist, who died on Nov 1, had practiced medicine more than 50 years. He had his MD from the College of Physicians and Surgeons of Columbia University in 1884, and served as a surgeon in the Serbian Army in the Serbian-Bulgarian war of 1885-6. He was a major in the medical corps of the U S Army in the World War. He was president of the American Dermatological Association in 1914-15.

THE PHYSICIANS WIVES LEAGUE of Greater New York, Mrs William Robinson president, held a dinner dance at Delmonico's, Manhattan, on Nov 27. A tea was held at the home of Mrs S J Wilson of 910 Park Place, Brooklyn, on Nov 3

Onondaga County

DR. O W H MITCHELL is nominated for president of Onondaga Medical Society for 1938. Others scheduled for election at its next meeting Dec 7 are Dr Leon E Sutton as vice president, Dr Dwight V Needham as secretary, and Dr James F Cahill as treasurer

Two censors will be chosen from these nominees: Dr Joseph R. Wiseman, Dr Edwin H Shepard, Dr P E Menzies and Dr Wardner D Ayer, to fill the expired terms of Dr Shepard and Dr C D Post. Named to be elected as delegate to the state society meeting is Dr John J Buettner, and as delegates to the Fifth district branch meeting, Dr George L Wright and Dr Raymond J Pieri

DR JULIUS H HESS, child specialist from Chicago, gave an illustrated talk on "The

Care and Development of Premature Infants" at a meeting of the Onondaga Medical Society on Oct 28 in Syracuse

Dr Hess, who is professor of children's diseases at the University of Illinois Medical School and staff consultant at six Chicago hospitals, was accompanied by State Commissioner of Health Edward S Godfrey, Jr., and Dr Elizabeth Gardner, both of whom spoke on the program

Ontario County

A STRIKING FEATURE of the Canandaigua *Daily Messenger* of Oct 26 was a "Medical Section" of six pages, devoted to the doctors and hospitals of Ontario County. The leading article was a history of the County Medical Society by its Secretary and Treasurer, Dr D A Eiseline. Dr F C McClellan, President of the County Society, was author of an equally prominent article surveying various county medical organizations and activities. Several columns were given to the County Public Health Nursing Service and to the county campaign against tuberculosis. An article by Dr Morris Fishbein on fake cancer cures filled a quarter page. Pictures of local physicians were sprinkled through the supplement.

Putnam County

DR MAURICE LENZ, Chief of the Department of Radiation Therapy at New York Presbyterian Hospital, spoke before the Putnam County Medical Society at the regular monthly meeting, held November 3, at Carmel Country Club. Doctor Lenz's subject was "Radiation Therapy in Cancer"—*John T Jenkin, Secy*

Queens County

SUPPORT OF THE "Cavalcade of Sensations," variety revue and circus sponsored by the Queens County Cancer Committee, is urged upon Queens residents by Dr Mandel Weinstein and John H Schleif, chairman and treasurer, respectively, of the committee in a special Cancer Crusade Week appeal.

The "Cavalcade," which will feature stars of the stage, screen and radio, will be presented on December 2, 3, 4, and 5 at the Jamaica Armory.

DR WILLIAM METCALFE STONE, who had practiced in Flushing since 1900, died at Columbia-Presbyterian Medical Center on Oct 29. During the World War Dr Stone was medical director for the draft board in Queens. At his death he was medical

director of Flushing Hospital and Dispensary.

DR JOHN J KINDRED, who died in October, was a member of Congress for ten years and was identified with medical legislation at Washington and obtained large grants for local improvements. Press accounts recall that Dr Kindred often made the *Congressional Record* read like a supplement of a medical journal. He once converted the entire House into a class for a lecture on trachoma.

He was the founder and operator of two sanatoria for mental diseases and once owned a monkey farm in Florida, where he intended to conduct experiments in rejuvenation through the use of monkey glands. At his death he was professor of medical jurisprudence at John B Stetson University, Deland, Fla., and was consulting physician at St John's Hospital, New York City Children's Hospital and Kings County Hospital.

Dr Kindred was admitted to the practice of both medicine and law. In 1927 both he and his wife, Ella Welbon Cramer, a Vassar graduate, were admitted to practice before the Supreme Court.

That same year he read into the *Congressional Record* an eight-page survey on the use of monkey glands for rejuvenation.

Rockland County

DR CHARLES DEMAREST KLINE, who died Nov 3, was a past president of the Rockland County Medical Society and of the First District Branch of the State Society, and had served also as vice-president of the state body. He was health officer of Nyack for forty of the forty-three years since the post was created.

Steuben County

THE ANNUAL MEETING of the Steuben County Medical Society was held at Bath, November 11. The following officers were elected for the ensuing year: *President*, A E Richmond, MD; *Vice-President*, Roger Haggerty, MD; *Secretary and Treasurer*, R J Shafer, MD; *Censors*, M A Place, MD, James Sanford, MD, L A Thomas, MD, S H Bean, MD, E P Smith, MD; *Delegate* (Second District), L M Kysor, MD (2 years); *Alternate Delegate*, Glen Whiting, MD.

Dr L A Thomas, Chairman of the Workman's Compensation Committee, discussed the proposed fee schedule for upstate New York. The following motion was

unanimously adopted by the Society "The Steuben County Medical Society protests any fee cut from the fees established for the Metropolitan area in 1935 for the medical treatment and care of injured employees and recommend a uniform fee schedule for the entire State of New York."

Dr Morton L Levin, representing the subcommittee from the State Cancer Commission, addressed the Society on the Cancer Survey which is being undertaken in Steuben County.

Dr James Cole read a paper on "The Surgical Treatment of Bone Tuberculosis." Dr John M Swan read a paper on "The Function of a Cancer Committee in a General Hospital"—*R J Shafer, M D, Secy*

Suffolk County

AT THE ANNUAL MEETING of the Suffolk County Medical Society, held on October 18 at Riverhead, the following officers were elected for the ensuing year *President*, Earl M McCoy, M D, *First Vice-President*, W W Gardner, M D, *Second Vice-President*, Roger Dexter, M D, *Secretary*, Edwin P Kolb, M D, *Treasurer*, Grover A Stillman, M D, *Censors*, Paul Nugent, M D, F McGilvery, M D, W Eller, M D, Victor K. Young, M D, L Barber, M D

Warren County

DR. MANFRED SAKEL of Vienna, was guest speaker at a meeting of the Glens Falls Academy of Medicine on Oct. 29 in the auditorium of the Crandall Library. His subject was "The Pharmaceutic Shock Treatment of Psychoses and Its Mechanism." The Albany Medical College cooperated in arranging the program.

Westchester County

THE ANNUAL MEETING of the Medical Society of the County of Westchester was held at New York Hospital, Westchester Division, on Nov 16. Brief addresses were made by the retiring and incoming presidents. Officers were elected as follows:

President, Dr Erich H Restin, *Vice-President*, Dr Ralph T B Todd, *Second Vice-President*, Dr Henry J Vier, *Secretary*, Dr Merwin E Marsland, *Treasurer*, Dr James G Morrissey, *Censors*, Dr Morley T Smith and Dr Roy D Duckworth, *Delegates* (Two Years), Dr Merwin E Marsland and Dr Laurance D Redway, *Alternate Delegates* (Two Years), Dr Harry Klapper and Dr George C Adie

AT THE MEETING ON October 19 Dr Will

Cook Spain, associate physician at Post-Graduate Hospital and chief of its Allergy Clinic, presented a paper on "Bacterial Allergy" and Dr George Flamm, attending physician at Cumberland Hospital and an attending physician in Allergy at the Roosevelt Hospital O P D presented an illustrated paper on "Pollen Allergy." Dr Flamm brought with him a most interesting film showing in colors, the more common trees and plants whose pollens are of interest to the allergist and also showing methods of diagnosis and treatment. Dr Andrew A. Eggston and Dr Henry B Wightman opened the discussion and those who participated in the general discussion included Drs Virginia Langworthy, Dorothy Lang, M DeM Touart, Arthur F Heyl, and Fairfax Hall.

A resolution to amend the By-Laws and provide for an increase in the amount of the annual dues was carried by a considerable margin over the required two-thirds vote, after a lengthy discussion.

THE WESTCHESTER COUNTY MEDICAL SOCIETY has appointed a Special Committee on Hospitals under the chairmanship of Dr Ralph T B Todd, the Society's Second Vice-President.

This Committee is to be representative of every general voluntary hospital in the county. In a letter announcing this Committee, the Society's President, Dr Morley T Smith, stated that the duties of this Committee would be:

"1 To study the report and recommendations of the Hospital Survey for New York, as they apply to the organized care of the sick in Westchester County.

"2 To study and report on all local and general hospital problems that are of concern to the medical profession throughout the County."

Dr Smith stated further that "the field of activity charged to this Committee is obviously a very important one presenting a great opportunity for service both to the profession and to the public."

The Hospital Survey for New York recommended that a "permanent representative and authoritative planning group" be established in each of the metropolitan counties which could "review and pass upon all proposals for major capital expenditures in the interests of organized care of the sick, especially those for increasing the bed capacity of voluntary municipal and county hospitals." It is expected that the Medical Society's Committee may eventually be the nucleus of such a planning group for Westchester County.

Hospital News

Cross Infection in Children's Wards

WHAT GOOD DO WE DO "a cute little feeding case" when we "lean over his bed and laugh and talk and spray him with assorted droplets containing probably several varieties of streptococcus, pneumococcus, etc?" This rather disquieting picture was presented before the Children's Hospital Section of the American Hospital Association Convention at Atlantic City in September in a paper by Dr Philip S Barba and Dr John C Williams of the Germantown Dispensary and Hospital, of Philadelphia, now published in *Hospitals* (Chicago)

Or "how kind is the nurse to a colicky baby who picks him up after she has leaned on the infected side-bars of a crib containing a child with streptococcus mastoiditis?" Or, even if the nurse is careful, "frequently we have seen a nurse wash her hands and don a gown to help a resident or visiting physician go over a patient, while the doctor, unwashed and ungowned, sits on the edge of the child's bed and then passes on to the next case" These doctors confess that they have "had the unfortunate experience of having a newborn contract tuberculosis from a nurse, and of having an attractive child with a mild secondary degree burn contract scarlet from a solicitous pupil nurse who developed the disease a few hours after carefully feeding the child his supper"

Intensive Course for Nurses

Such unfortunate happenings lead these authorities to recommend complete physical examinations and tests of every attendant who might convey contagion to the little patients, and to urge a course of immunization treatments, carried as far as practicable. Some hospitals feel that the reactions are too severe to warrant complete immunization against diphtheria, scarlet fever, and typhoid. Most important, basically, is the education of the nurse in preventing infection. Say the authors of this paper

The nurse should receive an intensive course in hygiene before she is allowed to enter the wards

How can we expect these girls to know anything about infection until they have been taught? Even after years of experience we find doctors as well as graduate nurses making the most obvious slips in technique. Apparently familiarity does breed contempt, especially if we can find some one else to be the goat when we try to explain our serious accidents

We feel that practical teaching is the most important. Have them touch an agar plate, or cough on plates, or talk to a plate. Let it incubate, then show them what growth is possible from an apparently harmless contact. Such demonstrations may set up phobias in a few of the girls, but it will save a host of infections if the possibility of transmission is well planted, and then carefully cultivated through the following years

If a wave of cross infection should start in a ward the personnel should be carefully examined for carriers. Aseptic technique, if not already in use, should be instituted to a degree needed in operating room technique. Extra nurses should be put on duty if necessary

Certainly if we can afford to spend hundreds of dollars for antitoxin or for serum we can afford to spend the few dollars necessary to provide adequate nursing. Why should children die as the result of factors readily controlled by the use of proper hospital technique?

Little Patients May Exchange Germs

So much for cross-infection by the nurses. But there is equal danger that the little patients may infect each other, for the child who is admitted with this or that ailment may also be just coming down with something else, or just recovering, and may spread it broadcast. This side of the problem was presented before the Section on Public Health and Hygiene of the Illinois State Medical Society by Dr Maurice L. Blatt, of the Cook County Hospital in Chicago and St. Vincent's Orphanage

The precautions taken at these institutions are thoroughgoing. First, of course, the child passes through the examining room for a complete history and physical examination and such laboratory work as is vital, so that the child applying for admission with pneumonia, bronchitis, upper respiratory tract infection or any other ailment may be segregated, if found to

have chickenpox, measles, whooping cough, scabies or any other infectious disease

The next step is to inject twenty to thirty c.c. of its father's or mother's blood "No child is admitted to the general hospital, no matter what his disease, unless he is given whole blood from a parent Wassermann and Kahn tests are done on parental bloods before administered, except in emergency" Says Dr Blatt "It is our belief, based upon our experience with measles, chickenpox, and whooping-cough, that immune bodies exist in the blood of most adults, immune bodies not only to those diseases whose organisms are known, but to other diseases such as the common cold, and perhaps some types of streptococcic infection We believe that by so injecting our incoming patient we can produce a degree of passive immunity equal to the injection of one-half the same amount of normal human serum into the same individual Furthermore, we believe that in rheumatic infections, in the endocarditides, in choreas, in pneumonias or influenza, the giving of whole blood in this way is in no way harmful, does not produce shock, and seems to us to be beneficial"

A contagious disease card is made out for each child, showing dates of previous contagious diseases and immunizations In

this way, if infectious diseases start, one recognizes immediately which child needs protection

Fond Parents Fended Off

Visitors are discouraged Even the fond parents can view their offspring only through glass windows Masks are worn by the nurses As we learn

Masks are valuable in a Children's Hospital A number of infections of the respiratory tract decrease in those departments of the hospital in which masking of nurses and attendants is strictly enforced

Our experience with the impervious deflecting mask at St Vincent's Infant and Maternity Hospital has warranted its use for the past three years Nurses in the premature ward at the County Hospital are constantly masked—no one is allowed in the ward unmasked

The discomfort and inconvenience of the common gauze mask is in a large measure overcome by the form fitting cellophane mask.

As to specific immunization one cannot say too much As the general trend of active immunization of the populace outside of the hospital increases, to just that degree will the hospital cross-infection decrease As diphtheria immunization, scarlet fever immunization and whooping cough immunization increase in the general populace, through the efforts of the pediatrician and the public health official, to just that degree will the percentage of cross-infections in these diseases fall, and it is on the future of preventive inoculation that we pin our greatest hopes

Risks of Explosion in Anesthesia

IT IS UNFORTUNATE THAT many of the anesthetic agents in use at the present time are inflammable and are therefore liable to explode under certain conditions, says *The British Medical Journal* While anesthetic explosions are relatively infrequent they are very alarming for everybody concerned when they do occur Coste and Chaplin of the London County Council recently carried out some investigations to discover what conditions render these vapors explosive They found that a mixture of ethyl chloride and air is inflammable when the proportion of ethyl chloride in the mixture lies between five and twenty per cent, and in the case of ether vapor and air a concentration of two to eight per cent can be ignited

If ether vapor is mixed with nitrous oxide the risk of explosion is doubled, as any concentration of ether between 15 and sixteen per cent is inflammable, much the

same is true of oxygen and ether It was also found that the vapor produced by bubbling oxygen, with or without nitrous oxide, through ether in a Boyle's machine or Shipway's apparatus produced a very inflammable mixture, even if the gases were passed through the chloroform bottle as well it was still possible to explode the mixed vapors

On the other hand, the risks of explosion in the course of open ether anesthesia were found to be very slight Samples of air taken at a distance of two inches from the patient's mouth contained too small a percentage of ether to ignite, even after the anesthetic had been in progress for one hour and ten ounces of ether had been used

Both ethylene and acetylene have proved explosive when mixed with oxygen for the purposes of anesthesia, and cyclopropane, too, is a potential source of danger

This is, of course, only one side of the problem. Of even more importance to the anesthetist is the source of the spark which may explode the anesthetic mixture. A red-hot cautery or a diathermy electrode is an obvious danger, especially when used in or near the mouth. Less obvious are the risks attached to the use of electric light bulbs on esophagoscopes or bronchoscopes. If these bulbs are loose or if the insulation is faulty a spark may arise, at least two explosions appear to have been caused in this way. A hot dental needle has also been responsible for an explosion, though the temperature of the metal was below that required to produce red heat.

Lastly, there are the sparks produced by static electricity. Several writers have

drawn attention to the possibility of the frictional electrification of equipment used in operating theatres. Considerable static voltages were produced and regarded as creating a serious risk of anesthetic explosion, merely by the movement of blankets over metal operating tables.

The rubber wheels of trolleys, etc., often provide insulation enough to allow dangerous charges to accumulate. One way to prevent this accumulation is to earth the metallic parts of the equipment by a light chain trailing on the floor. Another method is to use electrically conducting rubber for tires, tubing, breathing bags, etc. Samples of such rubber have been made and its use should go far to eliminate the danger of explosions.

Newsy Notes

IT HAS BEEN FOUND THAT of 3,151 attending physicians in New York City on outpatient services only, but 109 or 3.5 per cent were paid in 1935, and of the 18,636 positions on hospital staffs in New York City the occupants were paid some salary in only 8.3 per cent of the cases.

A SURVEY SHOWS THAT few hospitals make any provision for the perpetuation of their property investment by creation of a depreciation reserve fund to cover normal wear and tear and obsolescence. When plant or equipment needs renewal, nothing has been laid by for it. In any other work this precaution is considered elementary.

DR HAVEN EMERSON SAYS in *Hospitals*: "The most important lesson which it appears to me has been learned from the Hospital Survey for New York is that the cost of care of the sick is too much for the sick alone to carry. The well should expect to pay for the care of the sick. The great benefits of voluntary collective thrift, and a reasonable regard for the expected and inevitable hazards of life combine to persuade each of us to set aside while in health and in our years of productive ability, those sums which will secure for us good care in illness."

"No single device of organization to facilitate individual investment in institu-

tional care of sickness promises so much as the pre-payment plan now so well established among the voluntary hospitals of many of our cities, and generally in Great Britain."

A BILL REQUIRING LICENSING of all New York State nurses, those fully qualified to care for acute cases, as well as practical nurses to care for convalescents or chronic cases in the home, was the subject of lively discussion at the meeting of the New York State Nurses' Association recently at Lake Placid.

Marion Sheehan, director of the division of public health nursing of the state department of health, outlined the proposed bill to the convention delegates and described its purposes.

The bill, she declared, will define what constitutes the practice of nursing and set up a system of penalties to be imposed upon those found practicing without a license so that "the full protection of the law can be assured the public."

Among liberal features suggested was one permitting all qualified out-of-state nurses to register in New York State upon presentation of credentials satisfactory to the state education department.

"WHEN WITHIN A SHORT PERIOD two patients made claims upon the hospital for

the loss of false teeth, we realized something had to be done to prevent such property from being thrown out unintentionally by nurses and maids. Our solution was to provide ointment jars (3 inches high, 3½ inches in diameter and costing 9 cents each), one of which was placed in every patient's medicine cabinet or bedside stand. On the outside of the jars was stenciled in letters ¾ inch high 'Dental Work Only'. This has proved an obvious reminder that artificial dentures should be placed in the special container. In nearly five years since these were installed, no complaints have been registered."—F. Stanley Howe, director of Orange Memorial Hospital, Orange, N. J., in *The Modern Hospital*.

THE THIRD ANNUAL DINNER of the visiting staff of physicians and dentists of the Queens General Hospital, Flushing-Hillcrest, was held at the North Hills Country Club, Douglaston, November 16.

Three hundred visiting staff members attended. Dr. Carl Boettiger, president of the medical board and director of medicine, and Dr. Marcus D. Koegel, medical superintendent of the hospital, spoke.

A CLINICAL SOCIETY has been formed at St. Joseph Hospital at Lawrence by hospital and local physicians, and will hold monthly meetings throughout the year.

PHYSICIANS OF THE HERKIMER Academy of Medicine have asked the Herkimer Memorial Hospital board to create a hospital staff of sixteen members. The hospital never had an official staff, say physicians, and therefore was never officially recognized by the American College of Surgeons. The purpose is to obtain recognition of the hospital nationally and to guarantee a high grade of medical ethics.

AN ALL TIME HIGH in the number of patients treated in New Rochelle Hospital was recently reached when the daily census of the hospital, which has a capacity of 147, advanced to 189 patients.

THE UNITED HOSPITAL CAMPAIGN Committee recently issued two statements pertaining to Bronx hospitals.

One was that Montefiore Hospital, Gun Hill Road, and Bainbridge Ave., is the best-equipped of all voluntary hospitals in the New York metropolitan area for the treatment of chronic diseases.

The other was that 'Bronx hospitals are not provided adequately with medical social service departments.'

"SUPERINTENDENTS WILL DO WELL to stand around their hospitals occasionally with their hands in their pockets and watch the wheels go around. Superintendents of the sex who have no pockets will have to do something else with their hands, but the point is—stand around once in a while with nothing particularly on your mind and see what the others are doing"—Will Ross in *Hospitals*.

YONKERS PROFESSIONAL HOSPITAL celebrated its fifth anniversary with a dinner dance at Arrowhead Inn, Riverdale, which was attended by 250 physicians, nurses and their guests, on October 19.

Dr. John A. Faiella, Deputy Public Health Commissioner and president of the hospital, was chairman of the dinner committee. He was assisted by Dr. Al Amandes Morrone.

In a brief message of greeting contained in the souvenir program, Dr. Faiella cited the rapid growth of Yonkers Professional from an institution of twenty-six beds and a personnel of six, to one of 123 beds and a personnel of sixty-eight, "an increase of over 500 per cent in the past five years."

THE JEWISH HOSPITAL of Brooklyn was given an oil painting of Dr. Adolph Bonner and a bronze plaque of Dr. John Linder on November 3 at the Leon Louria Auditorium in honor of their service as members of the medical staff.

DEPARTING PATIENTS OF THE Methodist Episcopal Hospital in Brooklyn carry away menus of the hospital meals as souvenirs. "I want my friends to see what good food they gave me," explained one patient.

LORENZ J. BROSNAN, Esq

Counsel, Medical Society of the State of New York

Medical Societies—Power and Right to Enforce By-Laws

An interesting case involving the power which a medical society may exercise over the conduct of its members recently was decided by the highest Court of one of the States on the Pacific coast *

The action was brought against the K. County Medical Society, a constituent of the State Medical Society in that jurisdiction which in turn was one of the constituent societies of the American Medical Association. The purpose of the suit was an attempt to recover damages from the defendant Society, and the codefendants K. County Medical Service Corporation, and certain officers and members of the Society and of the Corporation, upon charges that they had induced Doctors S and M, of the County Society, to breach a contract entered into between them and the plaintiffs.

The action was disposed of in the lower Court, and the appeal was determined upon a record which took into consideration only the allegations made by the plaintiffs. The defendants addressed an application in the nature of a demurrer to the plaintiffs' charges in order to test the case upon the theory that insufficient facts to constitute a cause of action had been alleged, assuming the truth of all of the plaintiff's charges.

The fact situation, therefore, which will be summarized in some detail, is taken from the complaint, and may not conform in all respects to the facts that would have developed had the defendants in the case ever been called upon to give their version of what had transpired.

The K. County Medical Society embraced nearly all the physicians practicing in the locality, and according to the charges, the Society had created for its members a virtual monopoly of the medical profession, controlling fee schedules and dominating the professional practice of its members, and in various ways controlling their conduct by threats of discipline or expulsion.

It seems that two physicians, S and M, members of the Society, had about twelve years before organized what was called the

Associated Physicians Clinic, and had engaged in group medical contract practice with various large business firms. They had undertaken to furnish medical and surgical care and hospitalization to employees of such firms at one dollar per month per capita. The plaintiff, P, it seems, had entered into a contract with Drs S and M whereby he was employed as manager of their contract department. His duties were to secure new contracts, to collect fees, and generally manage the business end of the venture. P claimed that the contract was a profitable one for him and that it was intended to continue for an unlimited term.

The defendants at all times had been opposed to independent clinics of the type so conducted, and it was claimed were so opposed to such contract practice as "it tended to injure the monopoly enjoyed by the society and its members in the medical profession and practice, and tended to deprive members of the society of much of their exorbitant and excessive fee practice." It was claimed that about two years before the suit was started defendants began a concerted movement to destroy such contract practice, with the result that Drs S and M, subsequent to the action taken by the defendants, committed in furtherance of a conspiracy, abandoned their practice and in so doing were obliged to breach their contract with P.

It seems that the Society had organized its own group clinic under the corporate name of K. County Medical Service Corporation. The charges alleged that such clinic was identical to the Associated Physicians Clinic with which P was connected. It was also claimed that the defendants had induced an able and trusted employee who had worked for the Associated Physicians Clinic to desert the Clinic and work for the Society's corporation.

The Society had during its alleged campaign against independent clinics passed an amendment to its by-laws tightening up on the matter of discipline of members. The by-law in question, after stating various routine grounds of discipline, provided that a member "who shall engage in contract practice unless the same shall previously have been authorized by the Board of Trus-

* Porter v. Medical Society 58 Pac (2nd) 367

tees of the Society, or who as physician or surgeon shall serve on the staff of, or shall perform work in any institution or group or organization unless such services or work shall previously have been authorized by the Board of Trustees of this Society, or who as physician or surgeon shall serve on the staff of, or shall perform work in any institution or group or organization unless such services or work shall previously have been authorized by the Board of Trustees of this Society shall be liable to censure, suspension or expulsion"

Shortly after the passage of the said amended by-law, it seems that the Society threatened to expel Drs S and M unless they abandoned their contract practice including their contract with P and demanded that they should turn over to the Society and its subsidiary clinic all their books and records relating to their practice as the Associated Physicians Clinic. The said physicians at first refused to comply. Shortly a certain Dr C, who was a leading member of the Society, (named as an individual defendant in the action) filed written charges signed by some thirty other members against Drs S and M accusing them of unethical conduct in violation of the by-law referred to and seeking their expulsion from the Society.

Shortly after the charges were so filed, S and M abandoned their agreement with P and gave up their contract practice.

Both the lower Court and the Appellate ruled that the foregoing failed to state a cause of action against the defendants. In affirming the judgment of dismissal, the Appellate Court said in its opinion

The constitution, charter and by-laws of the medical society constitute a contract between the members of the society which the courts will enforce if not immoral or contrary to public policy or the law of the land. That is to say, Doctors S and M, under their contract with the medical society, were required to obey the by-laws of the society or by breach thereof

subject themselves to the penalty of suspension or expulsion from the society. It is not at all material how selfish or unselfish the objects of the medical society are if same are legitimate. It cannot be successfully contended that the medical society did not have the right to adopt the by-law in question. Whether such by-law or rule was just, reasonable or wise is a question of policy which concerns only the medical society and its members. The medical society, in the enforcement of its by-laws for the direct purpose of benefit to itself and to its members is not answerable for damage incidentally resulting to a third person. So long as one remains a member of the medical society, such member can be compelled under his contract with the society to obey the laws, rules and regulations of the society or suffer the penalty of fine, suspension or expulsion.

The weight of authority is to the effect that in pursuing its legitimate objects an association has the right to coerce a member by fine, suspension or expulsion, and the association will not, nor will its members, be liable in damages to those who may be directly or indirectly injured by such efforts. So long as a member remains in the association, he is subject to the coercive effect of a penalty exacted for breach of a by-law of the association. If he does not desire to abide by the obligations of his contract of membership, he may abandon his membership. No right of appellants, who were non-members, was invaded by the respondent medical society when it established its code of ethics and insisted upon compliance therewith through threat of expulsion of an offending member. We agree with counsel for respondents that, viewed as an association engaged in promoting the interests of its membership, the enforcement of solidarity by threat of expulsion of one of its own members creates no cause of action for the incidental damage resulting to an employee of that member who has a contract of employment "for an unlimited term."

It is interesting to note that in so ruling the Court cited a number of cases, as authorities for its decision, which dealt with the powers enjoyed by labor unions to control the actions of their members.

MISSISSIPPI VALLEY MEDICAL SOCIETY AWARD

The Mississippi Valley Medical Society offers a cash prize of \$100, a gold medal and a certificate of award for the best unpublished essay on a subject of interest and practical value to the general practitioner of medicine. Entrants must be ethical licensed physicians, residents of the United States, and graduates of approved medical schools. The winner will be invited to present his contribution before the next annual meeting of the Mississippi Valley Medical Society (September 28, 1938), the Society

reserving the exclusive right to first publish the essay in its official publication—the *Radiologic Review and Mississippi Valley Medical Journal*. All contributions shall not exceed 5000 words, be typewritten in English in manuscript form, submitted in five copies, and must be received not later than May 15, 1938. Further details may be secured from Harold Swanberg, M.D., Secretary, Mississippi Valley Medical Society, 209-224 W C U Building, Quincy, Ill.

Across the Desk

A Medical Famine in the Great Open Spaces?

"Do you have any doctors around here?" asked a traveler in a remote wilderness region of the Ozarks

"Hell, no, we don't want no doctors," replied the bewhiskered native, shifting his tobacco from one corner of his mouth to the other

"What do you do when somebody is sick?" said the traveler

"We give him a good drink of whisky"

"Suppose that doesn't do him any good, what then?"

"Then we give him another drink"

"And what if that doesn't help him?"

"We naturally give him another"

"And if that doesn't make him better?"

"Stranger, if a man is so sick that three drinks of whisky don't do him no good, then nobody can't do nothing for him"

This simple and direct medical philosophy, which requires no long years of study in medical school, and no messing and fussing around with test-tubes in a laboratory, prevails in some areas where the population is too sparse to support regular physicians. But it has been seized upon by our eloquent socializers who would immediately have the government organize a rural medical service to care for these neglected denizens of what are sometimes styled the sticks

Scrutiny Shows Up the Facts

Every doctor is naturally in full sympathy with the belief that every sick person in the United States should have the benefit of medical care, but it also happens that every doctor is of a scientific turn of mind, so the level-headed men of the Bureau of Medical Economics of the A M A have taken the trouble to explore this situation with the same care that the surgeon takes to find the infection that perils the life of his patient

It turns out that there are 241 counties scattered through thirty states which had 2,000 or more persons for each physician in 1936. These are the counties, then, if any, that would need a relief corps of government doctors. The ratio of one doctor to 2,000 population was used because the Committee of Hygiene of the League of Nations

set this figure in 1931 as the minimum for efficient rural medical service. A little investigation, however, makes one wonder if these counties are so badly off, after all. The boasted British system, it seems, permits a physician to have 2,500 persons on his "panel," besides others for whom he cares as private patients, and in Sweden, with its special regulations for rural medical care, the average number of persons per physician for the entire country is 2,660. Indeed, it appears that "in no European country having any considerable rural population with systems of state medicine, compulsory insurance or special provisions for rural districts has this ratio of 2,000 persons per physician been reached for a majority of the rural sections"

Plenty of Doctors Within Reach

We must not forget, either, that every such county is surrounded by other counties, which may have plenty of doctors, so that in these days of telephones, automobiles and splendid roads, it may have an entirely adequate medical service. Take the thirteen counties in Florida with more than 2,000 people per physician. Neighboring counties within fifty miles have thirty-four hospitals with 2,633 beds, of which only 1,433 were occupied in 1935. Certainly no one can complain of a scarcity of medical facilities there. In Kansas the six counties with few resident doctors do not in any case border on each other, so that all have other well-supplied counties in easy reach, and, we find, the hospitals in the adjoining counties were less than half filled in 1935. To send more doctors into these counties might merely be taking the bread from the mouths of doctors already there, without bettering the local medical situation in the least.

People, too, who inhabit the back districts are often backward in their medical customs and beliefs. We are reminded by the Bureau of Medical Economics that an ignorant, illiterate, and socially backward community will prefer patent medicines, home remedies, witch doctors, quacks, or cultists even when its residents recognize that they are sick.

Sometimes they accept sickness as fate and do nothing about it—whole sections of the population had be to educated to the fact that they were suffering from hookworm disease before they saw any need of medical service. Ignorant mothers often summon untrained local midwives in preference to trained obstetricians, and doctors in the counties that were studied report that patients wait to call a qualified physician until they have exhausted the resources of nostrum and home-made medication.

America Leads the World in Medical Care

Secretaries of state medical societies are unanimous in reporting that no complaints as to lack of medical service and practically no requests for additional physicians have been received from these counties supposed to be suffering from a medical famine. Present indications are that these counties are getting all the medical care they demand. If doctors are scarce in "bush" regions, we must remember that a great general movement of the people from the country to the city has been in progress during the past fifty years, and it is only natural and inevitable that the doctors should move with the population.

Despite all this, however, there is no sign that rural health has been neglected, and there has been no time in recent decades when there were not more physicians per unit of population in the United States—and in both urban and rural districts—than in any other country on the globe. It is a well-known fact that many doctors who have moved from country locations to nearby cities have kept all their rural patients, and, thanks to the automobile and good roads, can take as good care of them as before, or even better. Sometimes the doctor's prestige and practice in the countryside are increased by his new city address and hospital connections.

Acid Test Tells

An acid test of medical efficiency is the death rate, and if these rural counties are suffering so frightfully for lack of medical care, then it should show up clearly in the mortality statistics. The interesting fact, however, as pointed out by the Bureau of Medical Economics, is that these counties have lower death rates than their states at large. In Alabama, for instance, "the

recorded rate is actually lower in the majority of these counties than in the state as a whole," and "if there is any lack of medical service in these counties, it is not reflected in the death rate." In Florida only two of the thirteen counties studied have a death rate higher than the state average, and in nine the rate is below the rural state average. State after state show the same thing. In Kansas the average death rate is 103, while the rates of the six counties suffering a dearth of doctors are 74, 38, 45, 49, 66, and 5 per 1000.

Many others might be cited. The simplest explanation seems to be that the old-time law of supply and demand is here working before our eyes—the doctors go where they are needed most, in city and town, where the incidence of morbidity and mortality is heaviest, and do not stay where they are least needed, in regions where the people live and work in the open air and sunshine, eat plain food, go to bed early, and retain their health and vigor.

A Story from Mexico

The experiment of providing state medicine for the rural population is being tried in Mexico, we learn from an interesting article in the *Virginia Medical Monthly*. In Mexico, it seems, ninety per cent of the population live in the country, while ninety per cent of the doctors are to be found in the cities, so the government is providing medical service for the rural population. Several different plans are in force in different parts of the country. As a large part of the population are of Indian or mixed blood, the doctors encounter some curious situations.

A young doctor who was sent to a village in southern Mexico danced with a betrothed Indian girl with flashing eyes and dazzling smile. A big row ensued, as the jealousy of her man was roused, and the engagement was broken off. In the emotional upset that followed, we are told, the girl tried to kill herself, but only fractured her femur and pelvis. Under government medical and surgical treatment the fractures healed, but she failed to walk. Treatment for her hysteria was of no avail.

Finally the family called in the village medicine man, who danced about the girl's bed, uttered his mystic incantations, and ended by making a bonfire of the young doctor's undershirt. He then told the girl

to rise and walk, which she did, completely cured. If the plan of the medical reformers in this country is to send our promising young M.D.'s out to compete with the local

quacks, cultists and voodoo performers of the wilder regions, perhaps it would be well to include in each kit a dozen spare under-shirts.

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

RECEIVED

Some Fundamental Aspects of the Cancer Problem. Symposium Sponsored by the Section on Medical Sciences of the American Association for the Advancement of Science. Edited by Henry Baldwin Ward. Quarto of 248 pages, illustrated. New York, The Science Press, 1937. Cloth \$2.50.

Recent Advances in the Study of Rheumatism. By Frederic J. Poynton, M.D. and Bernard Schlesinger, M.D. Second edition. Octavo of 380 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc., 1937. Cloth, \$5.00.

Dextrose Therapy in Everyday Practice. A Survey of the Literature, 1900-1936 on the Experimental and Clinical Studies Applicable to Medicine and Surgery. By E. Martin, Sc.D. Octavo of 451 pages, illustrated. New York, Paul B. Hoeber, Inc., 1937. Cloth, \$3.00.

Maternal Deaths—The Ways to Prevention. By Iago Galdston, M.D. Octavo of 115 pages. New York, The Commonwealth Fund, 1937. Cloth, \$75.

Baby Epicure. Appetizing Dishes for Children and Invalids. By Elena Gildersleeve. Duodecimo of 141 pages. New York, E. P. Dutton & Company, Inc., 1937. Cloth, \$1.75.

To the kitchen-untrained male, this seems like a very nice cook book and he would enjoy being fed by the author.

The only drawback he sees is suggested by the title, "Epicure." Many of the recipes seem as if they required much time and skill.

WALTER D. LUDLUM

The Mind of Man. The Story of Man's Conquest of Mental Illness. By Walter Bromberg, M.D. Octavo of 323 pages, illustrated. New York, Harper & Brothers, 1937. Cloth, \$3.50.

The badge of genuine scholarship gleams from every page of this work by one of our

The Diagnosis of Nervous Diseases. By Sir James Purves-Stewart, K.C.M.G. Eighth edition. Octavo of 842 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$10.00.

The Thinking Body. A Study of the Balancing Forces of Dynamic Man. By Mabel Elsworth Todd. Octavo of 314 pages, illustrated. New York, Paul B. Hoeber, Inc., 1937. Cloth, \$4.00.

The Abdominal Surgery of Children. By Sir Lancelot Barrington-Ward, F.R.C.S. Second edition. Octavo of 333 pages, illustrated. New York, Oxford University Press, 1937. Cloth, \$9.00.

Biological and Clinical Chemistry. By Matthew Steel, Ph.D. Octavo of 770 pages, illustrated. Philadelphia, Lea & Febiger, 1937. Cloth, \$8.00.

REVIEWED

younger psychiatrists, and it is a credit to the medical profession that research material should be presented in such a distinguished style. Most of the reviews which have appeared in the literary journals have stressed the absorbingly original handling of the history of medicine and mental diseases, but the importance of the book to the profession is that this historical drama is deftly developed to explain the origins and meaning of modern psychiatric treatment and technique.

In this book, perhaps more than in any other like it, it is made clear to what extent medicine was originally psychiatry, and how in the course of history, physical medicine conquered almost all but the complex problems of the human being as a personality. Dr. Bromberg most clearly reveals how it is these personality problems which

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W. 42nd St., N. Y. C.) postage prepaid. Order must be accompanied by remittance covering published price.

BOOKS

Number 231

are the object of modern psychiatric investigation and treatment. In this way, the physician has a superior opportunity to understand the significance of modern psychiatric technic, such as psychoanalysis, psychobiology, etc., in the light of the needs which they were developed to fulfill. In this sense, the book reflects the dynamic qualities of movement rather than the merely static descriptiveness of a purely historical work.

Dr Bromberg's treatment of the whole realm of faith healing, psychotherapy, and treatment of mental cases will appeal to every physician. For the practitioner it is a storehouse of vibrant information effectively conveyed, for the specialist it is an excellent example of the modern fusion of psychiatric technic

SAM PARKER

Legal Medicine and Toxicology By Thomas A. Gonzales, M.D., Morgan Vance, M.D. and Milton Helpert, M.D. Quarto of 754 pages, illustrated. New York, D. Appleton-Century Company, 1937. Cloth, \$10.00

It would be impossible to describe this book. It may best be understood by extracts from the foreword by Doctor Martland. He says "This book is one of the few authoritative works on legal medicine and toxicology in this country. It should become the hand book and daily guide for the coroner, the coroner's physician, the county physician, the medical examiner, the toxicologist and the pathologist. It will be of aid to the police schools and crime laboratories.

Finally the surgeon, the internist, especially the cardiologist, as well as the members of the legal profession, criminologists, and those who are interested in the occupational hazards and poisons of present-day industry should find a wealth of material and detailed instruction in this work."

The official standing of the authors as medical examiners of the City of New York and professors in three of the medical colleges of New York City as well as the Police Academy would be sufficient guarantee of the value of this book.

HENRY F. GRAHAM

Electrocardiography By Chauncey C. Maher, M.D. Second edition. Quarto of 254 pages, illustrated. Baltimore, William Wood & Company, 1937. Cloth, \$4.00

The author states in the preface to the first edition of his work that "there is need for a treatise on electrocardiography for use by the general practitioner, the medical student and the specialist, exclusive of the cardiologist." His work clearly fulfills that need. It is not to be recommended as a

reference book on the entire subject of electrocardiography.

The author has arranged his material well, and has expounded his explanations clearly. He is to be complimented on having used the *Criteria for the Classification and Diagnosis of Heart Disease*.

The reviewer would take issue with him on one point in his chapter "The Electrocardiogram in Coronary Disease." He interprets curves as corroborative of the clinical diagnosis of acute coronary thrombosis involving the anterior or the posterior surface of the left ventricle as the case may be. In view of the fact that branches of both the right and the left coronary supply parts of both the right and left ventricles and because an infarction may involve parts of both ventricles if properly situated, it seems preferable to limit electrocardiographic localization of infarcts to either the anterior wall or the posterior wall of the heart.

E. P. MAYNARD

The Common Neuroses Their Treatment by Psychotherapy An Introduction to Psychological Treatment for Students and Practitioners. By T. A. Ross, M.D. Second edition. Octavo of 236 pages. Baltimore, William Wood & Company, 1937. Cloth, \$4.00

Seventeen years have elapsed since the appearance of the first edition of this book. In this interval, psychiatry has made marked strides in the treatment of the neuroses. However, the views presented by the author then are continued, with many new examples used to illustrate the principles involved. It is his contention that the majority of patients suffering from neurosis can be treated by the general practitioner. The book consequently is addressed to him with the view in mind that he should be equipped to treat such individuals. Because of his vast experience in treating mental patients, the author has been able to offer many helpful suggestions in the treatment of the neuroses. However, one may take issue with him that the majority of patients are not difficult to treat successfully.

Followers of Freud will find little solace in the book. In this edition the author has given less space to Freudian psychology, and has omitted a chapter on the Application of the Freudian Method.

JOSEPH L. ABRAMSON

The Normal Encephalogram By Leo M. Davidoff, M.D. and Cornelius G. Dyke, M.D. Octavo of 224 pages, illustrated. Philadelphia, Lea & Febiger, 1937. Cloth, \$5.50

The authors have met a pressing need in compiling this work. Depending on

whether or not fundamental brain anatomy is understood, nothing can be more confusing or more illuminating than an encephalographic survey. Through this text, the neurologist, internist and roentgenologist can find a wealth of aid, particularly desirable for those men to whom encephalography is an exceptional rather than a routine examination.

The text is profusely illustrated by actual roentgenograms, lucid sketches and diagrams, all clearly labeled. Chapter division is also highly commendable, rendering the text easily accessible for ready reference, something to which our foreign colleagues might well pay heed.

Since the work seems to so completely fulfill the requirements of its title, it is the sincere wish of the reviewer that the authors refrain from a second and enlarged edition long enough for this present one to become thoroughly familiar to those of us who need a text of this sort for information and reference.

GEORGE W. CRAMP

Biological Time By P. Lecomte du Noüy. With foreword by Alexis Carrel, M.D. Octavo of 180 pages. New York, The Macmillan Company, 1937. Cloth, \$2.00.

This is an interesting volume dealing with the familiar subject of time from a rather original point of view. The conception carries with it a phase of relativity. The problem is explained in the first part, its application to the healing of wounds and tissue culture is described in part II, and the last part is devoted to a discussion of time from the author's standpoint. The book contains a wealth of interesting information and should be of interest to those active in the field of biology and medicine.

MAX LEDERER

Physiology and Pathology of the Heart and Blood-Vessels By John Plesch, M.D. Octavo of 188 pages, illustrated. New York, Oxford University Press, 1937. Cloth, \$5.25.

The author of this volume looks at the circulation in the light of mechanics and hydraulics. It is a novel method for the consideration of problems dealing with cardiac decompensation, arterio-sclerosis, hypertension, etc., that have taxed the ingenuity of medical men for many years. It abounds in formulae that represent mathematically the dilatability of the blood vessels, the systoles of auricles and ventricles, the venous pressures of the lesser and greater circulations. It stresses the importance of the blood volume, the rate of blood flow, and the diastolic filling of the ventricles. It endeavors to explain a variety of cardiac ailments upon a mechanical basis. Especially interesting are the author's views on circulatory shock, congestion and

edema. Practical therapeutic suggestions are interspersed frequently. Circulatory shock is regarded as an example of blood volume deficiency, the loss of venous tone giving rise to insufficient diastolic filling. Relief is obtained by the application of heat, placing the patient in a horizontal position, stimulating the vaso-motor nerves, and administering glucose. Caffein, digitalis and camphor are not indicated.

In many respects the author's views run counter to long established theories. Where the author is skating upon thin ice, he resorts frequently to the phrase, "in the light of our present knowledge." The little volume contains much food for thought. It will have served a useful purpose if it will aid in the rationalization of the physiology and pathology of the heart and blood vessels.

SIMON FRUCHT

The Endocrines in Obstetrics and Gynecology By Raphael Kurzrok, M.D. Octavo of 488 pages, illustrated. Baltimore, Williams & Wilkins Company, 1937. Cloth, \$7.50.

A book by Kurzrok, whose contributions to the new endocrine physiology have been so important, compels attention. He has recorded the brilliant researches of Allen, Aschheim, Aschner, Collip, Corner, Doisy, Engel, Frank, Friedman, Hartman, Hisaw, Novak, Smith, and others too numerous to mention here—the whole story of the most brilliant period of laboratory investigation in medical history.

He has used his own ample clinical material for correlation of data and comparisons with the conclusions reached by experiments with laboratory animals.

Highly technical here and there in gonadal hormone chemistry with detailed descriptions of methods of hormone assay, it is a real text with particularly interesting chapters on hormonal sterilization, the climacteric, functional sterility and toxemia of pregnancy. It is a valuable work of reference for the advanced student, the illustrations are excellent.

CHARLES A. GORDON

Safely Through Childbirth. A Guide Book for the Expectant Mother By A. J. Rongy, M.D. Duodecimo of 192 pages, illustrated. New York, Emerson Books, Inc., 1937. Cloth, \$2.00.

This little volume is a guide book for the expectant mother. It is written in simple language so that the woman of ordinary intelligence may learn and understand the physiological processes which go on in her body during pregnancy, labor and the postnatal period. She is told what to expect, what to do, and what to avoid. It is an excellent book, and is worthy of being widely recommended to patients by the doctor.

CANCER OF THE RECTUM AND RECTOSIGMOID

Notes on Surgical Treatment

FRED W. RANKIN, M.D., Sc.D., *Lexington, Ky*

Cancer of the rectum and rectosigmoid, insidious in its development, symptomless in its earlier stages, but usually of moderate grade of intensity and slow to metastasize, presents a health problem of paramount importance when one considers the fact that more than ten per cent of cancers occur in this segment.

Perhaps the most common evidence of a cancer in the lower bowel is blood found either intermittently or persistently on the stool or in the stool. This indication of some disturbance, much too frequently taken to originate from hemorrhoids and erroneously diagnosed without further investigation, is present in eighty-five per cent of all cancers of the rectum at some time during the course of the disease. Blood in the stool or on the stool obviously may come from any portion of the gastrointestinal tract. Bright red blood in the stool or on the stool almost invariably comes from the distal half of the large bowel or the rectum, and while it is not pathognomonic of a malignant lesion of the lower gastrointestinal tract, and indeed is the initial symptom in but one-half of the cases, it more frequently than any other symptom except pain, causes the individual to appear for an examination, and pain is an infrequent symptom of early cancer.

Probably the earliest symptom of bowel cancer is irregularity of bowel habit characterized by diarrhea or ex-

cessively increasing constipation, or alternating periods of both. Tenesmus is present in direct ratio to the proximity of the growth to the spluncnteric muscle. Pain, unfortunately, is late in occurring and is present only when the nerves of surrounding structures have been invaded.

When the lesion is situated at the rectosigmoid, a frequent early symptom is obstruction. A review of the anatomical structure of this segment readily reveals the reason the sigmoid empties into the top of the rectum at an angle as it crosses from left to right and because of this angulation and the lack of mesentery, any superimposed growth partially or completely obstructs the passage, giving rise to either subacute or acute obstruction.

When careful digital and, or, proctoscopic examinations are indulged in, the diagnosis of cancer of the rectum or rectosigmoid can accurately be made in one hundred per cent of cases. Neither of these examinations is difficult nor do they require any great amount of special knowledge or skill. With the patient in the knee-chest position if he be instructed to strain against the examining finger, the rectal lesion can easily be felt with the index finger. Occasionally even a rectosigmoidal growth will be found to come down to where it may be felt. If not, a proctoscopic examination makes possible accurate diagnosis in every case.

Feeling as I do that a knowledge of the grading of a growth is an invaluable

and not only in the selection of the operative maneuver, but in estimating prognosis, I have for the past twelve years routinely done a biopsy on every cancer of the rectum. Contrary to some beliefs, I have seen no evidence that by so doing cancer cells were disseminated to surrounding tissues or organs.

If in the presence of clinical symptoms of cancer of the colon or rectosigmoid, proctoscopy reveals a normal bowel up to or beyond the rectosigmoid, x-ray investigation is urgently indicated. I emphasize the fact, however, that this be resorted to only after proctoscopy has failed to show the offending growth. True it is, that occasionally after indulging in all efforts at differential diagnosis, the lesion is found to be benign, but how much better it is to establish the benignancy of a growth than to casually assume this verdict without proper examination when actually the lesion is malignant! The fact alone that one in every ten persons past the age of forty is doomed to die of cancer should cause one to use every available means to rule out the possibility of the patient in question being this victim.

But of what avail is the improved technic of surgeons, roentgenologists, and radiologists if they are not given the opportunity to make an early diagnosis? Who is to blame for delay in diagnosis which is admitted to be the principal cause for failure to cure cancer? Perhaps, as some hold, the chief cause for inoperability of cancer of the rectum and rectosigmoid, as of cancer elsewhere in the body, is the patient's dilatoriness in consulting a physician. This is due in part to the idea of the layman that until he suffers pain or complete disability from his ailment he is not obliged to "go to the doctor." He is not familiar with the significance of changes in bowel habit, irritability of the colon, and other symptoms that usually precede bleeding, pain or obstruction, a fact which justifies us to indulge in constant repetition even to the point of being tiresome.

Equal in responsibility, it seems to me, is the failure of the consulted physician to make an adequate examination, thus causing further delay. This failure results often in the tragic discovery of a cancer at an operation scheduled to

be for hemorrhoids. Actually, somewhere between ten and twenty per cent of cancers of the rectum have within the period of their symptoms been operated upon under the diagnosis of hemorrhoids. Even the most cursory examination of the rectum for a low-lying cancer would prevent this, and proctoscopic examination would always indicate the proper location and diagnosis. These factors have been so often repeated that it seems incredible in our enlightened times that any physician should accept a patient's diagnosis of hemorrhoids without an examination, or treat a patient for hemorrhoids without a careful inspection of the lower part of the gastrointestinal canal. At the risk of being a bore, let me again repeat that any case of bleeding of the rectum should be looked upon as due to a malignancy until it is definitely proved that the lesion is a benign one.

Treatment

Once an accurate diagnosis of cancer of the rectum or rectosigmoid has been made, one may consider two types of offensive against it—surgery and irradiation, either singly or in combination. Unquestionably, there are certain types of cancer of the rectum which can be cured by radium, then too, it is of great value as a palliative procedure for inoperable and recurring lesions. In the latter instance, bleeding is frequently controlled, the tumor recedes and occasionally so-called inoperable tumors are rendered removable. Some growths can be made to disappear by the direct application of radium around the base and over the surface of the tumor. When it is remembered, however, that forty-six per cent of cancers of the rectum have metastasized to the lymphatics at the time of resection, and that if resection is not done we have no proof of the absence of metastases, it seems reasonable to conclude that radical extirpation offers the most satisfactory results in the vast majority of cases. Undoubtedly, there is a field for the combined use of the two and I am certain that as knowledge of radium increases, this field will be enlarged.

I mention only briefly the recently instituted procedure of destruction of can-

cers of the rectum by surgical diathermy Strauss and his coworkers have recently reported a series of cases treated by this method in which a satisfactory number lived for a long period of time and in many of which adequate palliation resulted, although the patient ultimately died of cancer. Certainly, local destructive measures have their place in the surgeon's armamentarium, but like all offensives directed against cancer, their limitations and indications should be rather sharply defined.

Any local destructive agent which gets rid of a cancer and saves the splintcric mechanism is commendable, provided its use is not extended beyond its limitation. Obviously, one cannot destroy cancers of the rectosigmoid with surgical diathermy because of the danger of breaking into the peritoneal cavity. Also, one cannot fail to take into account the fact that although rectal cancers metastasize slowly into the regional lymphatics, at resection the specimens of nearly one-half of the cases show glandular involvement to have already taken place.

Destruction of malignant growths by radium or surgical diathermy, or any other agent which is local in its application cannot hope to influence distant metastases and therefore should be limited to the role of palliation, or that of an adjunct. Unquestionably there are elderly individuals in a debilitated state and with growths which are locally inoperable who will be benefited by desiccation of the growth with or without colostomy, but for the vast majority of sufferers from cancer of the rectum I am still convinced that the radical extirpative maneuvers applying the principles of cancer surgery to the rectum just as to the breast, lip, or other parts of the body, still pertain.

Preoperative Preparation

Recently it has been my custom to extend the preoperative period of preparation on patients with cancer of the rectum and colon from three or four days to seven days, or longer. This rule holds only, of course, when there are no evidences of acute intestinal obstruction. During this time the patient is given a diet high in calories but low in residue

and is subjected to repeated irrigations of the bowel with hot saline. A preoperative blood transfusion has many times proved helpful in assisting the patient through a radical operation. When there is marked debility or evidence of anemia, a transfusion is routinely given preoperatively. A former practice of administering intraperitoneal vaccine composed of mixed streptococci and colon bacilli, has been abandoned after having been found to lack the value once attributed to it.

Selection of Operations

Statistical study has proved that the application of as radical procedures as possible to cancer in the rectum yields higher percentages of five year cures than less extensive measures. However, it is essential that a surgeon have at his command knowledge not only of the radical technic, but of several other types of maneuver if he is to maintain a desirable operability rate along with a reasonable hospital casualty list. The standards for such selection should at all times be flexible, and must be governed by the patient's general condition and the stage of the growth, its mobility, coexisting debilitating diseases, and other complications.

In operating on 576 patients for cancer of the rectum and rectosigmoid since January 1927, I have found the following four operations, given in order of their desirability, but not necessarily applicability, to be the ones of my choice.

- 1 Radical combined abdominoperineal resection in one stage

- 2 Radical combined perineoabdominal resection in two stages

- 3 Colostomy and posterior resection (Mummary)

- 4 Palliative procedures and local excision

In the three operations which have been most satisfactory in my hands, colostomy is, without question, always considered an essential step. Nor should it be an objectionable one! Once a patient has accustomed himself to a properly made colostomy, he can easily control it and thus wear it gracefully and without stigma. The objections offered to colostomy by both the profession and

aid not only in the selection of the operative maneuver, but in estimating prognosis I have for the past twelve years routinely done a biopsy on every cancer of the rectum. Contrary to some beliefs, I have seen no evidence that by so doing cancer cells were disseminated to surrounding tissues or organs.

If in the presence of clinical symptoms of cancer of the colon or rectosigmoid, proctoscopy reveals a normal bowel up to or beyond the rectosigmoid, x-ray investigation is urgently indicated. I emphasize the fact, however, that this be resorted to only after proctoscopy has failed to show the offending growth. True it is, that occasionally after indulging in all efforts at differential diagnosis, the lesion is found to be benign, but how much better it is to establish the benignancy of a growth than to casually assume this verdict without proper examination when actually the lesion is malignant! The fact alone that one in every ten persons past the age of forty is doomed to die of cancer should cause one to use every available means to rule out the possibility of the patient in question being this victim.

But of what avail is the improved technic of surgeons, roentgenologists, and radiologists if they are not given the opportunity to make an early diagnosis? Who is to blame for delay in diagnosis which is admitted to be the principal cause for failure to cure cancer? Perhaps, as some hold, the chief cause for inoperability of cancer of the rectum and rectosigmoid, as of cancer elsewhere in the body, is the patient's dilatoriness in consulting a physician. This is due in part to the idea of the layman that until he suffers pain or complete disability from his ailment he is not obliged to "go to the doctor." He is not familiar with the significance of changes in bowel habit, irritability of the colon, and other symptoms that usually precede bleeding, pain or obstruction, a fact which justifies us to indulge in constant repetition even to the point of being tiresome.

Equal in responsibility, it seems to me, is the failure of the consulted physician to make an adequate examination, thus causing further delay. This failure results often in the tragic discovery of a cancer at an operation scheduled to

RELIEF OF PAIN BY PHYSICAL MEASURES

RICHARD KOVACS, M D, *New York City*

Pain is undoubtedly the commonest of all symptoms. From the patient's point of view it actually dominates the whole field of medicine and is usually the symptom which brings the patient to the physician. There is nothing that gains more prestige for a doctor than the ability to relieve pain. In a patient with a painful condition the good physician should be able to make a reasonably adequate diagnosis at the outset and then proceed immediately to make him comfortable.

It is axiomatic that treatment of any painful condition must be primarily directed towards removing or ameliorating its cause. Generally speaking, pain may originate in two ways:

1 The pain may have an obvious organic cause, such as inflammation or swelling and it is definitely localized in one spot or area. The sensation of such pain is conducted to the sensory cortex through well-recognized tracts the same as the sensation of heat or cold.

2 The pain may be diffused and unlocalized. Such pain is often associated with visceral disorders, in other cases it may be functional or psychogenic. In the latter case, the affected areas are unrelated to sensory nerve distribution, while in visceral conditions the pain is referred to certain parts of the skin and is associated with the sympathetic nervous system. The association of definite areas of the skin with the underlying viscera has an important bearing, not only from the diagnostic standpoint, but also regarding the application of physical measures. Thermal or other stimulation applied to certain areas will have a definite reflex effect in deeper structures.

Physical measures are being employed in a steadily increasing scope for treatment of painful conditions. Newer experimental and clinical studies have shown their place in the direct causal treatment of many of the physiological changes underlying pain. This has been notably so in inflammatory disorders and traumatism. The most important physical agents such as massage and simple heat are instantly available almost anywhere, physical measures offer the advantage

that their dosage can be fairly accurately controlled, and they can be usually directly applied to the seat of the disorder, when used for symptomatic treatment, there is no danger of habit forming by physical measures and there is very little likelihood of untoward effects due to idiosyncrasy.

Action of Physical Agents

Every physical agent when applied to the body exerts a primary physical action and this in turn brings about secondary physiological and clinical effects. On the basis of their primary action, physical measures have been classified as mechanical, thermal, electrical, and chemical. It is an interesting fact that measures of different physical nature may accomplish similar physiological effects. The work of Lewis¹ and others has cleared up this seeming contradiction. Lewis showed that so far as the skin is concerned, mechanical, electrical, thermal, and chemical stimuli—within physiological limits—all produce a similar response of the skin vessels. This response consists of a primary and local dilatation of the minute vessels of the skin, a widespread dilatation of the neighboring strong arterioles—brought about entirely through local nervous reflex—and locally, increased permeability of the vessel walls. The extent and the slow or quick development of this skin reaction and the additional effect on deeper structures by reflex and direct penetration can be accounted for the differences between various physical agents and enables their selection according to clinical aspects and individual equation.

Mechanical Measures

Rest is a therapeutic measure of primary importance in all painful conditions which are aggravated by movement. Nature points the way—often overshooting the mark—by producing a protective muscle spasm in most acute injuries. Placing an injured part at rest by posture or by light splinting relieves pain and to a

Read before the Annual Meeting of the Medical Society of the State of New York, Rochester, May 26, 1937

certain extent favors defense and repair. Experience must decide how long such rest should be maintained, for prolonged immobilization, on the other hand, may delay recovery through lack of adequate circulation and lead to secondary pain due to stasis and adhesions, or deformity. Throbbing pain in an extremity in which there is acute inflammation can be markedly relieved by elevation of the limb.

Massage is an indispensable agent for relieving pain either by lessening peripheral tension in the acutely traumatized or inflamed parts or by dispersing the products of inflammation by direct pressure in later stages of trauma. Superficial gentle stroking exerts a sedative effect in referred or deep-seated pain. The pathfinding studies of Lucas-Champonnière of Paris have shown that massage may be successfully employed for relief of pain and spasm even in the most acute stages of an injury. Exercise in conjunction or independent of massage is often introduced to free painful movements by degrees. The static wave current and static sparks are valuable electrokinetic measures in relieving pain due to local congestion and minor adhesions.

Thermal Measures

Heating the body within physiological toleration has two distinct effects. (1) It brings about a local hyperemia and consequently speeds up the rate of removal of local tissue products (toxins or results of inflammation), and (2) it acts as a sedative in irritative conditions of sensory and motor nerves. Thus heating is perhaps the most valuable measure in combating pain, both from a causal and symptomatic standpoint. Recent clinical and research work in the application of general heating (fever therapy) in dosage lethal to thermolabile organisms (the gonococcus and the spirochaeta pallida) proved it is to be an important factor in the causal therapy of painful conditions arising from such bacterial activity.

In gonorrheal arthritis stubbornly resisting all forms of therapy, it has been possible to give almost dramatic relief from pain with artificial hyperpyrexia.

Cold is a negative condition, a decrease of molecular vibrations of the tissues due to extraction of heat by an application be-

low normal temperature. Mild degrees of cold, like mild degrees of heating, are distinctly sedative. Cold applications often give prompt relief in localized inflammatory conditions. There is not much difference between the effects of the prolonged application of a hot water bottle and an ice bag and consequently there is little justification for much argumentation over their respective merits. Heat produces an immediate vasodilatation, whereas cold effects an initial vasoconstriction, both result in a secondary localized hyperemia and both effect a varying degree of "derivation" in the deeper circulation.

It is often a matter of individual sensory reaction in an inflammatory condition whether there is more relief from hot or from cold applications.

Thermal measures for the relief of pain are to a certain extent interchangeable, one can often make up for less intense effect in the depth by prolonged application on the surface. Generally speaking, in localized acute painful conditions mild forms of local heating and the avoidance of all pressure are most effective, hence the preference for radiant forms of heating—luminous heat or infrared—to heavy hot water bottles or to diathermy. When there is much surface tension due to swelling, moist forms of heating are preferable. In chronic deep-seated congestive conditions diathermy is more effective because the action extends deeper, in addition the close-fitting electrodes prevent surface cooling. Reports about specific pain relieving effects by short-wave diathermy in acute inflammatory conditions need further clinical corroboration and especially comparison with controls treated by simple radiant heating. No other demonstrable effect except that of less surface and more penetrating heating has been proven so far about short wave diathermy.

Mild general heating is of value in pain which is not localized, or which arises in deeper organs or affects several parts, especially joints. Full hot baths, electric light baths, hot air cabinets, general diathermy or autocondensation are helpful in generalized pain—rheumatic conditions, etc.—and give relief by increasing general metabolism, decongesting deeper organs, and relieving vascular

stasis. Hot sitz-baths are employed to relieve pelvic pain due to congestion

Counterirritant Measures

Irritating the skin by some physical agent for the purpose of relieving some other irritation is known as counterirritation. Crude methods of vesication, sinapism, and liniments have been employed empirically for ages to relieve pain. The observations of Lewis have helped to bring about a better understanding of the biophysics of counterirritation while modern physical methods offer many more plausible and more efficient counterirritants. The old-fashioned liniments still fill a distinct need for home use, and for this purpose are preferable to some of the widely advertised, more expensive, and potentially more dangerous electric contraptions—"violet ray" and "home diathermy" outfits.

The *monoterminal high-frequency* or *Oudin* current administered through a glass electrode from the high voltage terminal of a diathermy apparatus will exert either mild surface heating or mild counterirritation, according to the degree of sparking employed. There is also a gentle stroking effect, due to the moving of the glass tube over the skin. This treatment is almost a specific for the relief of pain in neuralgia of the skin nerves—intercostal, supraorbital, and occipital. Meralgia paraesthetica—a painful affection of the *n. femoris cutaneus* lateralis—is usually promptly relieved. The after-pain in many cases of recent traumatism—contusions, myositis and sprains—often responds to *Oudin* treatment, especially when preceded by mild heating.

Ultraviolet irradiation administered to the extent of a second or third degree inflammatory reaction over a painful area has been employed in treatment of neuralgia, myositis, and other rheumatic affections. Following such exposure with adhesive strapping, Eidnow² has claimed excellent results with one treatment of acute low back pain. The instinctive desire by patients for various degrees of sunburning in painful muscular and joint conditions is well-known. The clinical effects of such treatment can be explained partly by that of a mild protein "shock"

due to the absorption of the destroyed albumin and partly by the reflex stimulation from the irradiated zone.

Galvanism and ionization. Specific pain relieving effect is being attributed to the positive pole of the galvanic current on the basis of the physiological fact that there is a decrease of nerve irritability around the positive pole in a laboratory muscle—nerve preparation. In the human body the amount of current which may reach the nerves situated deeply in the tissues is extremely minute, hence its effect on the circulation, the promotion of resorption, and a certain amount of counterirritation explain the relief of pain more satisfactorily. This is corroborated by the observation that it seems to make no difference which pole is used over a painful area as long as treatments of sufficient duration and intensity are administered.

Newer work with ionization of vasodilating drugs—histamin and mecholyl—has demonstrated their efficiency for relief of pain and stiffness in rheumatoid arthritis and other rheumatoid conditions.³ The deposition of the drug in the deeper layers of the skin by the positive pole of the galvanic current and its slow absorption from there brings about a prolonged form of counterirritation in the area treated and also some systemic effects.

The difference in the action of these electrochemical and photochemical methods from the purely thermal methods is in degree, penetration, and duration, and needs suitable repetition in order to effect "bridging" or continued relief from pain between treatments. On the other hand more profound counterirritation may give longer periods of relief and may necessitate fewer treatments. Seasoned clinical experience is needed for selection of these measures and their combination with other forms of treatment.

Some Painful Conditions

In addition to the conditions already mentioned physical measures are effective for relieving pain in numerous other disorders. Among these are inflammations, acute and chronic, including rheumatic conditions, traumatism irritation of per-

ipheral nerves and of spinal roots, certain forms of referred pain, and circulatory disorders. The limited extent of this paper allows only a brief consideration of some of these conditions.

Pain from injuries. If the accurate diagnosis of the nature and extent of a recent injury does not warrant complete immobilization, the immediate employment of gentle stroking massage, applied principally to the periphery of the traumatized area will relieve pain by hastening the dissipation of swelling, the intermittent use of an ice bag may also be helpful. Subsequently an elastic bandage or strapping may be applied and the injured part elevated and kept at rest. British clinicians, notably Heald,⁴ praise the sedative value of a mild galvanic current immediately applied. Pain in the subacute and chronic stage responds to thermal measures, gentle massage, and exercise.

Pain from inflammatory disorders, including rheumatoid conditions. The value of appropriate thermal measures and posture in acute forms of this nature has been already stated. In chronic inflammatory conditions, pain due to pressure on terminal nerve endings can be relieved by deep heating, or various forms of counterirritation, or massage and electrical muscle stimulation. Pain due to congestion in deeper organs is partly relieved by stimulation from the surface and perhaps partly by the penetrating effect of thermal agents.

In chronic bursitis, myositis, fibrositis, and certain forms of neuritis, physical measures not only serve for symptomatic but also causal treatment. It is a too far-fetched application of the theory of focal infection to look for spectacular relief in those conditions by the elimination of suspected foci. Such lesions as a rule represent a low grade local inflammatory reaction with no bearing on any focal infection. Manipulative cults steal a march on the medical profession by the successful attack of such well-localized traumatic or rheumatic lesions by physical measures. It should behoove the scientific medical man to institute in these conditions at once appropriate physical therapy, combined with suitable constitutional treatment. The quest for a supposed focus may be carried on concurrently

The characteristic pain of true *neuritis*—which is at times of torturing intensity—demands, as a first line of attack, complete rest and relaxation. A fairly continuous application of gentle surface heating from radiant sources—avoiding any pressure—is eminently helpful in the acute stage which is best treated at the patient's home. In the subacute stage, skillfully applied diathermy will alleviate muscular spasm which is a definite factor in keeping up the pain. In chronic stages various forms of counterirritation may be indicated. In the neuralgias and other painful affections due to irritation of spinal roots or disease of the central nervous system (gastric crises, tabetic pains), both thermal and counter-irritant measures are helpful. In experienced hands physical measures will enable restriction of sedatives and narcotics to a minimum.

Pain in *peripheral vascular disease* may be due to either vasomotor disturbances causing a spasm such as Raynaud's disease, or to chronic inflammatory changes causing obstruction of blood vessels, such as arteriosclerosis or endarteritis. In vasospastic conditions, ionization with vasodilating drugs is especially indicated, in organic occlusion of blood vessels with involvement of the arteries and unimpaired capillary circulation, mild diathermy is helpful, in advanced cases elevation of the leg combined with most careful external heating kept at a constant temperature of 94 to 95°F or passive vascular exercise by pressure-suction apparatus promises relief.

In conclusion it is evident that in order to be effective and safe, physical measures must be applied with an appreciation of the underlying pathology and with a knowledge of the proper technic and the possible dangers involved. There are sins of omission—neglecting time-proven physical measures—and sins of commission—employing physical measures unskillfully or as mere placebos.

Summary

1 Physical measures play an important part in both causal and symptomatic treatment of painful conditions. Their principal advantages are that their

basic forms are easily available, they can be usually directly applied to the seat of disorder, and there is no danger of habit forming or idiosyncrasy

2 The principal physical agents for the relief of painful conditions are mechanical and thermal, counterirritant measures in the form of Oudin current, ultraviolet irradiation, galvanism, and ionization

have a small but definite scope of applicability

3 The painful conditions in which physical measures play an important part of treatment are traumatism, arthritic and rheumatoid conditions, chronic inflammatory conditions, neuritis, and peripheral vascular disease

Discussion

DR PETER IRVING, *New York City*—Two thoughts were inspired in my mind by reading Dr Kovacs' clear presentation of his theme—thoughts rather widely diverging and yet practically related. The first is that substitution of physical measures for medicines in the relief of pain has a far greater value than is generally realized both by the public and indeed also by physicians. The second, purely practical, that it would be well for us as physicians to find a better way than has yet been worked out to utilize these safer methods of pain relief to the fullest degree.

I must make it clear that I am speaking not as an expert in physical therapy but as a practitioner of general medicine who quite some years ago found that results of application of physical measures were better if a physician specializing in this work gave the treatments. I am not qualified to compare the values of the different measures Dr Kovacs mentions because I have not his experience or judgment in their application.

However, from observation of results obtained by thoroughly skilled physiotherapists for my own patients and observation of the unfortunate effects of unwise use of salicylates, barbiturates, etc., I consider myself justified in enthusiastically endorsing the use of physical measures, wherever possible, instead of sedatives and analgesics so widely used today.

I doubt if many of us have given much thought to the possibility of minor addiction to phenobarbital or even salicylic acid, and that physical and personality deteriorations may result therefrom. Of course we are all aware of the toxic psychoses that at times follow overdosing. But that continued lesser use may do much damage is not so well-known. I happen to have seen one hopeless elderly hypochondriac whose nightly habit of one tablet of medinal prevented any recon-

structive work and one elderly aspirin habitue who is on her way to an ultimate toxic and degenerative psychosis. In both, the medicine, not at once recognizable as a factor, and indeed not the only factor, is the immediate handicap that makes useless the other usual remedial efforts. Both are arthritics, both had good reason to receive the medicines, both had no notion that these drugs were harming them. In both cases the early and wise use of physical measures might have made unnecessary the too long-continued medication.

My other notion that we have not found the best way to make more easily available physical measures for pain relief flows from the fact I mentioned that I had myself found it inexpedient to tack on in my practice a proper physiotherapeutic service run by myself. As I understand it two things are necessary in applying physical measures and both require time. The first is wise choice of the measures which can only come out of experience and study of the case, the second is skillful and leisurely application.

I wonder whether it will not in the future be decided, particularly with relation to physical measures for the relief of pain, that we shall have to develop intelligent group practice, into which physiotherapy shall quickly and expeditiously fit. We do it in hospitals, why not in private practice? Do not, please, understand me as a proponent of any "plan" for group practice but merely as believing that modern rapid developments in medical treatment seem to justify an attempt to give our patients what they need, not just at a cost they can meet but with conservation of their time.

Relief of pain by medicines is quick but has dangers. Relief by physical measures is safe and better but takes time. How make it most widely available? I leave this thought with you.

PNEUMONIA IN NEWBORN AND STILLBORN INFANTS

MARGARET WARWICK, M D, *Buffalo*

From the Millard Fillmore Hospital

Every pathologist, who performs autopsies on newborn infants, is often at a loss to explain a pneumonic process which he finds in the lungs of babies who were stillborn or who died during the first few days of life, without clinical signs of pneumonia. Investigation usually shows that their mothers also were free of evidence of bacterial infection of any kind. This pneumonia may be in one or both lungs and may be in small, isolated areas, or affect all of one or both lungs. The affected areas are dark red and firmer than the surrounding tissue and resemble areas of hemorrhage or atelectasis so that the diagnosis must be made by microscopic sections, a procedure too often neglected in newborn infants. The affected alveoli and often the bronchi also, are filled with neutrophiles. The alveoli may be atelectatic but more often have been open, if not distended. Usually the neutrophiles are grouped around the solid constituents of amniotic fluid, such as small masses of bile salts, or cornified epithelial cells, aspirated before or during birth. The exudate usually varies in distribution or extent with the amniotic fluid constituents.

At the Millard Fillmore Hospital, consecutive autopsies have been performed on 500 infants who were stillborn or who died during the first ten days of birth. But fifty-two of these bodies were so macerated that satisfactory sections of the lungs could not be made, which left 448 that were examined for pneumonia. Of these 448, ninety-three (21 per cent), more than a fifth, showed a pneumonic process in the lungs as is shown in Table I. The ages of the affected infants are shown in Table II, nineteen (20 per cent) were stillborn and twenty-six more (28 per cent) lived less than 24 hours, making a total of forty-five (48 per cent), practically half, who must have had the affection at the time of birth. Also of the entire series, seventy-

nine (85 per cent) died within the first three days of life. This pneumonia must have some relationship to the process of birth for it is difficult to think that so many infants, cared for in a modern hospital could have become infected with bacteria after birth and die of pneumonia within three days. Furthermore, very few of the infants dying between the third and the tenth days showed pneumonia.

In the absence of any clinical symptoms in these infants or their mothers, it is difficult to believe that bacteria could have caused these cases of pneumonia. When these lungs were stained by Rosenow's modification of Gram's stain, only twenty-seven (29 per cent) showed any bacteria to be present. In these twenty-seven were included every lung which showed any bacteria at all, even a rare group or chain, although so few bacteria could not have caused the pneumonia. It is possible that a few bacteria could have been introduced into the lungs during attempts at resuscitation. The bodies of some of these infants lay in the ice-box for several days before consent for the autopsies could be obtained, and it seems possible that some bacteria, particularly saprophytes, may have proliferated into many after death, without being the cause of the pneumonia. So it is possible that bacteria must have played an important role in many less than the twenty-seven where bacteria were demonstrated. Even if this were not so, we have proof that seventy-one per cent, or nearly three-fourths, of the cases of pneumonia showed no bacteria at all in the lungs. This suggests that the etiology of pneumonia in newborn infants must be something other than bacteria. This is borne out by Table III which shows the percentage of bacteria found in each age group and only five per cent of the nineteen stillborn infants with pneumonia showed bacteria in their lungs, and of the forty-five who

were stillborn or died within twenty-four hours, only seven per cent showed bacteria in their lungs. The percentage gradually rises to seventy in the infants dying within thirty-six to forty-eight hours after birth. This increase in bacteria with age suggests that the possibility of bacteria being introduced into the lungs increases with the age of the infant.

A septicemia in the infant as the cause of the pneumonia, may be ruled out by the fact that inflammatory lesions are not found in any organs but the lungs. It is difficult to under-

stand how bacteria could have been introduced into the lungs of infants dying before birth or shortly afterward. Johnson has suggested that premature rupture of the amniotic sac might allow the entrance of bacteria to the body of the child with aspiration into the lungs, but Table IV shows that in this series, sixty-eight (74 per cent) did not have a rupture of the amniotic sac until twenty-four hours or less before birth. It is impossible to believe that the membranes could rupture, bacteria enter the uterus, be aspirated into the baby's lungs, and set up a definite pneumonic process within twenty-four hours.

Since the neutrophilic infiltration is found in the lungs only, we must think of the etiologic factor as having been aspirated into the lungs, and the substance most frequently aspirated into the lungs of newborn infants, is amniotic fluid. This fluid normally contains hard, scale-like, rolled-up, cornified epithelial cells which have been shed from the surface of the infant into the amniotic sac. In addition to these, masses of bile salts from meconium which has been passed through a relaxed sphincter into the amniotic fluid, is also often present. It has been definitely proved that premature respirations may take place *in utero* by stimulation of the respiratory center from asphyxiation due to some disturbance in the circulation in either the mother or the child. Many an infant as premature as three months has breathed and sucked in a large amount of amniotic fluid as it died, as shown by the fact that we often find the lungs of a macerated, premature infant filled with bile salts and cornified epithelial cells. However, premature respirations usually take place during the process of birth. If the birth be long or conditions are such as to cause an asphyxia, large amounts of amniotic fluid will be sucked into the lungs. If death follows immediately afterward, only fluid and the solid constituents will be found in the lungs, but if the infant lives a while, the toxic bile salts and irritative cornified epithelial cells may cause an inflammation in the delicate tissues of the infants' lungs and an exudate of neutrophils be thrown around them. It is well-known that silver nitrate in an infant's eye may cause an exudation

of pus, irritating gas has caused a pneumonic process in adults, and oil in children's lungs has caused a pneumonia (lipoid pneumonia), so it is reasonable to suppose that bile salts that have been proved to be toxic to tissues in various parts of the body, and the sharp, stiff epithelial cells which may be physical irritants may cause a pneumonic process in the lungs of newborn infants.

This type of pneumonia is, evidently, not toxic as is a bacterial pneumonia but it may fill the alveoli of the lungs and prevent proper aeration. In other words, this exudate, which has been attracted by a chemical or physical irritant, causes a mechanical obstruction of the lungs so that air cannot enter. The serious effects of this will be largely determined by the extent of the exudate. Small, isolated areas may still leave enough lung tissue unaffected to aerate to support life, but lungs filled by the exudate will have little chance of recovering air, and thus may be the direct cause of death.

The aspiration of amniotic fluid is very common in newborn infants and Farber and Sweet found it in eighty-eight per cent of their series. If it is as common as this, one must explain why pneumonia in newborn infants is not more frequent even than the twenty-one per cent found in this series. The reaction to the amniotic fluid may be determined by several factors, the most important of which is the length of time that the child lives afterwards. If it dies shortly after the aspiration of the fluid no pneumonia will have chance to form. Also the amount of the toxic solid constituents, particularly the bile, of that the amniotic fluid may be determined factor. A fluid with a large amount of bile salts must be more toxic than one in which no meconium has been expelled. And last, but not least, the vitality of the child will be an important factor. It is possible that the large, strong infant may aspire some amniotic fluid either before or during birth, and be able to expel it. His respiratory efforts may be strong enough to aspirate sufficient air into the lungs to sustain life even if some alveoli remain solid. If the unaffected alveoli open up promptly and satisfactorily, the pneumonia areas may do little harm and either be replaced

by connective tissue or the leukocytes may liquify and be expelled with the solid particles, from the lung. Table V shows that the majority of the infants in this series were in poor condition at the time of birth. Only thirteen (14 per cent) were described as "good" while fifty-eight (60 per cent) were "fair" or "poor" and nineteen (20 per cent) were dead, hence, it is evident that, in this series at least, poor vitality was associated with the pneumonia. Some reason for the poor vitality of these infants is found in Table VI which shows that only twenty-four of the ninety-three had spontaneous deliveries and even these had complications, such as a long, hard delivery or the cord around the neck. The others all had abnormal deliveries.

In many of these cases, the pneumonic process might not have been the cause of death for Table VII shows that seventy-four (80 per cent) had other, grave pathological lesions which were sufficient to have caused death without the pneumonia. In other words we find the pneumonia occurring in infants which

were handicapped by other lesions which must have greatly decreased their vitality during their short lives. The pneumonia, if extensive enough, may prevent proper distension of the lungs and cause death in this way, but such cases are in the minority—nineteen (20 per cent). More often it occurred in the infant handicapped by abnormal deliveries or other disease conditions.

Conclusions

Pneumonia in newborn or stillborn infants is a definite pathologic process which cannot be diagnosed with certainty until the autopsy, because it so resembles hemorrhage and atelectasis. It is the result of aspiration of toxic bile salts and irritative cornified epithelial cells which form the solid constituents of

amniotic fluid which produces a non-bacterial irritation. The leukocytic exudation fills the lungs and prevents proper aeration and the extent of the process determines its severity. It is usually found in infants who have had long and complicated deliveries and who are either dead or in poor condition at the time of birth, and who are usually the victims of other pathological lesions sufficient to have caused death in themselves. Only a few died with no other pathological lesions and even those had some birth complications. Prevention of this condition is possible only by improving the prenatal conditions of infants and by improving, as much as is possible, the conditions under which they arrive in this world.

MILLARD FILLMORE HOSPITAL

Discussion

DR DOUGLAS ARNOLD, *Buffalo*—Thinking deeply about this subject, this paper of Dr Warwick's is very important.

About fifty years ago Dr Ahlfeld reported experimental work in which he described rhythmic respiration in the fetus, i.e. before birth. This really described the respiratory mechanism as in fine adjustment and practicing for its later work. This rudimentary (intrauterine) respiration in the human fetus is extremely important. He also described the inspiration of amniotic fluid (vernix, cornified epithelium, bile salts) as far as the upper respiratory tract. This occurs normally. Abnormally this refuse is sucked lower and in larger amounts.

Most physicians do not realize the importance of the correlation of asphyxia, atelectasis, and pneumonia in the newborn with the casual relation, intrauterine stress, that is, cerebral trauma (cerebral hem-

orrhage and edema) resulting in prematurely activating the respiratory center with pathologic inspiration of amniotic sac contents, or causing depression or paresis of respiration resulting in asphyxia, atelectasis, pneumonia or death. Dr Warwick as well as Farber and Wilson have significantly pointed out the high incidence of abnormal deliveries and cerebral hemorrhage in these cases.

This paper very definitely puts it up to the obstetrician to prevent either premature stimulation or later paresis of the respiratory center in preventing the inspiration of amniotic sac contents and thus preventing asphyxia, pathologic atelectasis, pneumonia, and death.

The paper also points a moral: "There is a time in every man's life when it behooves him to hold his breath and keep his mouth shut."

REWARDS OF A MEDICAL CAREER

I believe that in the future, as in the past, medicine offers a young man a career which will challenge the very best that is in him. Although his income will probably never be large, it will be adequate. The same intangible things which appeal to us today will still reward him. He will have a respected place in society and will have the realization that he is contributing a worth-

while service to society. He will be given the opportunity to deal with and know people in a personal way which should give him lasting enjoyment. His work will be interesting as long as he lives. I shall be happy and proud to have my sons enter the medical profession.—*From The Bulletin of the Hennepin County Medical Society, Minneapolis*

CLINICAL OBSERVATIONS ON TONSILLECTOMIZED CASES

ALBERT A. CINELLI, B.S., M.D., F.A.C.S., *New York City*

From the Oto-laryngological Department of New York Post Graduate Medical School and Hospital of Columbia University

The present regimented era of fashionable tonsillectomy has conveyed clinically definite criteria. Perusal of the literature reveals unsurmountable statistics.

The inferences derived from such colossal figures very often do not explain the failures in the not uncommon cases. It is with this thought in mind that these cases not benefited from tonsillectomy were critically studied for other possible foci.

It is in keeping to express the essential features of the histopathology and the physiological role of the lymphoid tissue of the pharynx. The lymphoid tissue of the pharynx known as Waldeyer's ring consists of faucial and tubal tonsils on the side, the pharyngeal tonsil or better known adenoid above and the linguals below. Except for the linguals the others appear fully developed at birth. The crypts in the faucial tonsils have been described as long and bifurcated and often constricted at the opening into the pharynx. This histological arrangement of the crypts makes the faucial tonsils an easy prey to infection. Infections in the tonsils causes a hyperplasia of the crypts with its concomitant desquamated epithelial debris and inflammatory cells, etc. These usually occlude the opening of the crypt into the pharynx making the tonsil an incubator for the bacteria. Since drainage is impeded, the passage not only of bacteria but also their autolysate and soluble toxins is hastened into the blood stream.

The histological arrangement of the crypts of lingual tonsils are a little different. They are short and wide and their openings into the pharynx are funnel-shaped. This fortunate arrangement accounts for the clinical fact that the lingual tonsils are seldom infected and rarely act as foci of infection. The lingual tonsils usually develop in puberty as a compensatory reaction to removal of faucial tonsils and adenoids. When inflamed and enlarged the symptoms are not toxic.

They are usually local symptoms of unproductive cough and a feeling of "lump" in the throat, etc.

The folds in the pharyngeal tonsils (adenoids) may easily become impacted with debris, but drainage is adequate and they seldom if ever act as an incubator like the crypts in the faucial tonsils. The symptoms are usually local.

The tonsils play a definite role physiologically. The lymphoid masses of the tonsils are cytogenic. Lymphocytes are produced in the germinal centers. This is substantiated by histological findings. These lymphocytes are constantly migrating through the epithelium, phagocytizing the bacteria into the crypts, to be destroyed in the lymph nodes. This protection of immunity acts only in a healthy tonsil. This is normally found in young children up to the age of six and seven. This explains the clinical fact that healthy tonsils removed under the age of five very often aggravate the upper respiratory infections instead of diminishing them. This is not applicable to adenoids. They may be removed at any age. Their physiological role is still a moot question.

It is generally agreed that diseased tonsils should be removed. There are times when it is not easy to make such a diagnosis. The hypertrophic tonsil with its acute inflammation, inflamed pillars, and typical history of sore throats offers no difficulty whatever. It is the small submerged normal looking tonsil with no history of sore throat that offers at times embarrassment to the clinician. In these cases a detailed history is highly important. Any history of sore throat or a coryza beginning with a sore throat, or some disturbance in the tonsillar region, should be elicited. On examination, see if some pus can be expressed from crypts by pressure. Retract anterior pillar and look for fibrous adhesions. Enlarged cervical gland in the angle of jaw is highly suspicious of infected tonsils. Dental sepsis, tubercular, leucic and Hodgkin's

disease must all be eliminated to account for this cervical enlargement. Discoloration of pillars, pharyngeal and palatal mucosa from a purplish hue to a deep red inflammation points to infected tonsils. A culture or swab from tonsils is clinically unimportant, as normally the tonsillar region is profusely bathed with many micro-organisms of extreme virulence especially the streptococcus hemolyticus.

A critical review of the general classification for which tonsillectomy is indicated will undoubtedly usher in some thought which will account for some of the failures.

- 1 Upper respiratory infections
- 2 Lower respiratory infections
- 3 Systemic diseases
 - (a) Rheumatic group
 - (b) Cardiovascular group
 - (c) Genitourinary group
 - (d) Miscellaneous conditions
- 4 The subnormal child
- 5 General infectious diseases

1 Upper Respiratory Infections

The following conditions—repeated sore throats, recurrent tonsillitis, head colds, otitis media, sinusitis—are usually termed upper respiratory infections. There is no question that T & A operations have benefited these conditions in the vast majority of cases.

The cases that were not relieved by T & A were carefully studied and the failures in most instances detected.

(a) In many cases the operation was incomplete. Small tonsillar infected tags remained which continued to act as a source of irritation.

(b) Incomplete enucleation of adenoid vegetations.

(c) Marked hyperplasia of the lymphoid tissue of the pharynx compensatory to T & A, which rekindled the train of symptoms.

(d) Found in several cases, the posterior wall of Eustachian tube removed by an overzealous operator, causing stenosis with cicatrization. The otitis media continued with gradual loss of hearing.

(e) Many children before operation were normal and had healthy tonsils and after T & A suffered with far more upper respiratory infections than before. Cases which are quite frequent today, due to the indiscriminate procedures of removing tonsils in a wholesale fashion, cannot be carefully studied in all their details, for when

removed, the protective function of the healthy tonsil is lost, thus rendering the throat more sensitive to the pathogenic bacteria present.

(f) An unrecognized antrum associated with diseased tonsils often clears the antrum. If pathology in antrum is quite advanced, same will continue the train of symptoms.

(g) Tonsillectomized children are better as regards colds, than children with infected tonsils, but no better than children with normal healthy tonsils.

2 Lower Respiratory Diseases

The most important are bronchitis and laryngitis. No relation has been observed between tonsillectomized patients and laryngitis. Two cases of laryngitis cleared up later after tonsillectomy by doing a wide intranasal antrotomy. Laryngitis in these cases was due to a postnasal drip. The alteration of voice associated with tonsillectomy is I believe overstressed. This is applicable more to adults than to children. In some cases it is due from extreme cicatricial contraction with tightening of palate by too wide a dissection. Singers, speakers, etc., should use their voices early in convalescence while the throat still feels stiff and before contraction of the palatal muscles begins. With this in mind, tonsillectomy should improve the voice, if any.

Bronchitis is associated with tonsillectomized patients more often than the statistics given by Kaiser. He states that tonsillectomy does not improve these conditions, in fact, it makes it worse. In many of the cases which I have observed, bronchitis was due to hypertrophied lingual tonsils, a compensatory reaction to tonsillectomy. Coagulation of these improved the bronchitis immensely. In other cases, a hyperplasia of lateral lymphoid pharyngeal follicles, by irritation, was the seat of the bronchitis. This was controlled immediately by one dose of x-ray therapy. In a good number of cases, a postnasal drip usually from an antrum and ethmoid, aggravated the bronchitis. The bronchitis was controlled by suction and drainage of the involved sinus.

It was observed in several cases that an unrecognized allergic factor was the responsible agent for the bronchitis in these tonsillectomized cases.

3 Systemic Diseases

(a) *Rheumatic group*. The prodromal symptoms of the rheumatic syndrome, the beginning muscular pains, the early teno-

synovitis, myositis, and neuritis associated with sore throat, offer the best results from tonsillectomy. I have observed a number of cases where first attack of acute rheumatic fever occurred in tonsillectomized patients. When the acute rheumatic fever or acute arthritis has set in, the prognosis from tonsillectomy should be guarded. If degenerative changes have occurred in the joints, the results are nil. However, if the tonsils are diseased, they must come out.

There are many etiological factors for acute rheumatic fever, and thereby cannot expect a cure in every tonsillectomy. Saroff's examination of the tonsils and tissues of neck at necropsy showed that the rheumatic virus may enter the body through any part of the upper respiratory tract as well as through the tonsils.

I have observed two cases of subacute rheumatism following tonsillectomy clear up after removing an infected tooth. One case greatly improved following the removal of an empyema of the gall-bladder. Several cases improved remarkably following a radical operation on a diseased antrum.

(b) *Cardiovascular diseases* Good results have been observed in the early cases of cardiac embarrassment where the nature of the conditions was slight and transient. Once degenerative processes started in the myocardium or endocardium the benefit from tonsillectomy was slight if any at all.

(c) *Genitourinary Group* Certain acute diseases of the genitourinary tract have a direct relation to acute tonsillitis. I have observed one case of acute hemorrhagic nephritis, two cases of pyelitis and one case of albuminuria of unknown origin—all clear up following tonsillectomy.

(d) *Miscellaneous conditions* The tonsil plays an important part with the thyroid gland. I have seen an acute thyroiditis following a tonsillectomy, and two cases of

adolescent goiter melt away by a tonsillectomy. In thyrotoxicosis, if the condition of the patient permits it, tonsillectomy is strongly indicated. If the thyrotoxicosis is far-advanced, treat the thyroid gland, then later remove the tonsils. I have seen a number of acute exacerbations on an operated thyroid flare up due to embedded diseased tonsils.

The tonsils apparently play no part in the various forms of allergy. Examination of hundreds of allergic patients revealed that tonsillectomy was of no value whatever.

4 The Subnormal Child

The general picture of the subnormal health in children is typical loss of weight and appetite, poor color, fatigues easily and high nervousness and irritability. When this condition is associated with a sore throat, the benefits from T & A are excellent. Those that do not respond, a diseased antrum or a chronic intestinal toxemia is usually the reason.

5 General Infectious Diseases

My experience with this group of cases has been markedly limited. Bailey reports 6,000 cases of diphtheria but he has never seen a death from diphtheria in a case in which the tonsils and adenoids had been removed.

Kerezturni and Park state "tonsillectomy has certainly no marked effect on susceptibility to scarlet fever within six months after it is done." Tonsillectomized children have less complications in diphtheria and scarlet fever than children with tonsils.

There is no relation between tonsils and chicken pox, mumps, whooping cough, and measles.

SLICKERS CAN BE OUTSLICKERED

"Beware of Swindlers" is the title of a very interesting article written by Dr. Frank J. Clancy, director, Bureau of Investigation, American Medical Association, and published in the October issue of the *Toledo Academy of Medicine Bulletin*.

Dr. Clancy outlined a number of the favorite tricks resorted to by the gyp artist and imposter and advises physicians how to protect themselves against racketeers. Boiled down his advice is as follows:

1 Don't cash checks for strangers

2 Don't cash checks or lend money to unknown physicians unless you are thoroughly satisfied they are bona fide physicians with a bank account and willing to keep their word.

3 Don't buy books, instruments, insurance, etc., from itinerant salesmen. Patronize local dealers.

4 When in doubt call your local Better Business Bureau, Chamber of Commerce, or similar agency.

5 If uncertain, telegraph the Bureau of Investigation, American Medical Association, for information and advice.

6 Always investigate before you invest.

CLINICAL ELECTROMYOGRAPHY

A Preliminary Study of Normal and Ischemic Muscles

BENJAMIN JABLONS, M D and PHILIP REICHERT, M D, *New York City*

That a change in electrical potential is a phenomenon concomitant with muscular contraction has been known since the work of Du Bois Raymond and Hermann which followed Oersted's invention of the galvanometer in 1820. This physiological fact has been elaborated into the electrocardiographic system of diagnosis by Einthoven, Lewis, McKenzie, and others.

The electrocardiograph has become a very valuable adjunct in the diagnosis of vascular disease of the heart. Much is known of the electrical variations in the cardiac musculature, but comparatively little analogous work has been done with skeletal muscles. Since ischemic areas in the cardiac muscles produced negative waves in the electrocardiogram, it seemed valuable to investigate the effect of artificially induced ischemia in the skeletal muscles and perhaps discover some correlation between such artificial ischemias and those produced in pathological conditions, such as arteriosclerosis and Buerger's disease.

Tracings were first made by the senior author with an amplified tube set devised by Wagner and with the Boulitte electrocardiographic apparatus in 1931, and later with the Nichols Chase Amplifying tube set in 1936, and with the Portographic apparatus of Sanborn and the Sanborn Cardiette in 1937.

Method

Electromyograms were made with a tube amplifying type as well as a string galvanometer. One plate of the electrocardiograph was fastened to the plantar surface of the foot on the outer aspect of the ankle, and the other plate was over the belly of the gastrocnemius muscle. The polarity was so arranged that contraction of the gastrocnemius would produce an upward deflection of the normal muscle, and the same plates and lead arrangement were thereafter used in all cases. It was

found that some practice and instruction were necessary so that the subject would contract the muscle regularly and evenly. That is so that successive contractions would be regularly spaced and of approximately the same amplitude. The patient is seated in a chair, absolutely at rest, with the foot resting squarely on the floor so that the heel is vertically beneath the knee, the leg being at right angles to the thigh. The patient raised the heel, keeping the ball of the foot in contact with the floor by contracting the gastrocnemius muscle of the leg being studied. The blood pressure cuff or tourniquet must be wrapped just above the knee so that varying degrees of ischemia can be produced without disturbing any of the set-up. The entire series of myograms are taken rapidly or slowly in order to minimize the effects of extraneous disturbing factors.

The curve looks not unlike the Greek letter Omega, and is monophasic in character, depending upon the location of the electrodes, i.e., polarity. The curve will either rise from a base line and return to the base line, or will drop from the base line and return to it. Its chief characteristic is that it is monophasic (the deflection is entirely in one direction, which we have called a positive direction) when the circulation through that muscle is intact. In the presence of disturbance of circulation, either caused by disease or mechanically through compression with a tourniquet, this curve assumes a diphasic character, i.e., deflection in two directions. In other words, the curve has a negative as well as a positive component. The diphasic character seems to be constant when ischemia of this skeletal muscle is present. The ischemia need not necessarily be of an extent sufficient to entirely obliterate circulation through the limb. Even in the presence of moderate ischemia, distortion of the curve occurs. This would suggest that in the presence of partial compression or increased irritability of the larger blood

Presented in part by the Senior Author in discussion before the American Heart Association, Kansas City, Mo., May 12, 1936

vessels, spasm of the smaller vessels occur which modify the normal character of the curve obtained

The present method of investigation is to take myograms of apparently healthy people, young adults without symptoms or signs of arteriosclerosis or peripheral vascular disease, and to produce by means of tourniquet, varying degrees of stasis in the circulation of the arm or leg

Fig 1 shows normal electromyograph obtained from the flexor muscles of the forearm in a normal boy sixteen years of age. Fig 2 shows the normal electromyograph obtained from the gastrocnemius muscle of a man forty years of age studied under varying degrees of ischemia. The rapidity of contraction seems to determine the angular or curvilinear character of the curve. Fig 3 shows the character of the various types of diphasic curves present in conditions where no evidence of organic obliteration of the blood vessels was present. Fig 4 shows the curve present in conditions associated with organic closure as indicated by history and oscilometric tracings and recordings. In older patients in whom there is sclerotic changes in the blood vessels of the walls as indicated by x-ray, but in whom there is no evidence of complete closure, the electromyogram is very often monophasic in character, but of exceedingly low voltage. It is needless to mention that the technic for recording this curve is essentially the same as that suggested for obtaining an electrocardiogram. It differs, however, in that the leads which constitute a complete circuit are placed at the required levels in order to obtain a record of the electric voltage sent up by the contracting muscles.

It is also possible to obtain a modified curve with the lead placed over both ankles, for instance in the case of peripheral vascular disease of the lower extremities. This would obviate the suggestion that this curve is produced by the mechanical riding of the lead on the skin of the leg. Incidentally, the same objection would hardly explain the presence of the diphasic variety of curve in peripheral vascular disease. We have found that compression of the limb with the blood pressure cuff inflated either close to or above the systolic pressure of

the subject will convert the monophasic into a diphasic curve. The value of this observation is apparent in the case history recorded below. We have also seen in this case the oscillogram produced by the recording oscillogram show an apparently normal amplitude and pulsation, which failed to give an adequate explanation of the symptoms complained of by the patient. In fact, the oscillogram in

Fig 1

this case was as good or even better than that observed in the normal limb. The electromyogram showing a diphasic character, indicated the cause of the pains of which the patient complained. It is interesting to note at the same time that therapy administered which was to release the spasm of blood vessels was reflected in the change from this type of curve into the normal monophasic curve. Changes have regularly occurred in all cases. We must conclude that they are directly due to the injected material itself. This type of diagnostic test is proving to

CLINICAL ELECTROMYOGRAPHY

A Preliminary Study of Normal and Ischemic Muscles

BENJAMIN JABLONS, M D and PHILIP REICHERT, M D, *New York City*

That a change in electrical potential is a phenomenon concomitant with muscular contraction has been known since the work of Du Bois Raymond and Hermann which followed Oersted's invention of the galvanometer in 1820. This physiological fact has been elaborated into the electrocardiographic system of diagnosis by Einthoven, Lewis, McKenzie, and others.

The electrocardiograph has become a very valuable adjunct in the diagnosis of vascular disease of the heart. Much is known of the electrical variations in the cardiac musculature, but comparatively little analogous work has been done with skeletal muscles. Since ischemic areas in the cardiac muscles produced negative waves in the electrocardiogram, it seemed valuable to investigate the effect of artificially induced ischemia in the skeletal muscles and perhaps discover some correlation between such artificial ischemias and those produced in pathological conditions, such as arteriosclerosis and Buerger's disease.

Tracings were first made by the senior author with an amplified tube set devised by Wagner and with the Boulitte electrocardiographic apparatus in 1931, and later with the Nichols Chase Amplifying tube set in 1936, and with the Portographic apparatus of Sanborn and the Sanborn Cardiette in 1937.

Method

Electromyograms were made with a tube amplifying type as well as a string galvanometer. One plate of the electrocardiograph was fastened to the plantar surface of the foot on the outer aspect of the ankle, and the other plate was over the belly of the gastrocnemius muscle. The polarity was so arranged that contraction of the gastrocnemius would produce an upward deflection of the normal muscle, and the same plates and lead arrangement were thereafter used in all cases. It was

found that some practice and instruction were necessary so that the subject would contract the muscle regularly and evenly. That is so that successive contractions would be regularly spaced and of approximately the same amplitude. The patient is seated in a chair, absolutely at rest, with the foot resting squarely on the floor so that the heel is vertically beneath the knee, the leg being at right angles to the thigh. The patient raised the heel, keeping the ball of the foot in contact with the floor by contracting the gastrocnemius muscle of the leg being studied. The blood pressure cuff or tourniquet must be wrapped just above the knee so that varying degrees of ischemia can be produced without disturbing any of the set-up. The entire series of myograms are taken rapidly or slowly in order to minimize the effects of extraneous disturbing factors.

The curve looks not unlike the Greek letter Omega, and is monophasic in character, depending upon the location of the electrodes, i.e., polarity. The curve will either rise from a base line and return to the base line, or will drop from the base line and return to it. Its chief characteristic is that it is monophasic (the deflection is entirely in one direction, which we have called a positive direction) when the circulation through that muscle is intact. In the presence of disturbance of circulation, either caused by disease or mechanically through compression with a tourniquet, this curve assumes a diphasic character, i.e., deflection in two directions. In other words, the curve has a negative as well as a positive component. The diphasic character seems to be constant when ischemia of this skeletal muscle is present. The ischemia need not necessarily be of an extent sufficient to entirely obliterate circulation through the limb. Even in the presence of moderate ischemia, distortion of the curve occurs. This would suggest that in the presence of partial compression or increased irritability of the larger blood

Presented in part by the Senior Author in discussion before the American Heart Association, Kansas City, Mo., May 12, 1936

be of considerable value in diagnosing early cases of peripheral vascular diseases, cases in which the disease has not produced sufficient organic change to show complete closure of blood vessels and arrest of circulation. These are the conditions where early diagnosis is extremely important since neglect at this stage may expose the patient to chronic progressive lesions which can not be eventually controlled. In these cases of unilateral involvement, the unaffected limb may serve as a control. At times when it is used for control study, the presence of a distorted curve is a sign of beginning involvement which would not otherwise be suspected.

Discussion

It is rather curious that this type of investigation has apparently not found clinical application up to the present time, particularly in view of the fact that intermittent claudication has for a long time often been termed "angina cruris." The use of electrocardiography in "cardiac angina" is well-known and has been extensively described. Many cardiologists have emphasized that in many cases of angina it is not always possible to obtain a characteristic electrocardiographic tracing in cases of cardiac angina. Whether this will prove true in cases of "crural angina" we do not as yet know. It will require considerable study along this line to prove this point. The experimental production of the diphasic curve by subjecting the peripheral vascular system to increasing amounts of compression as shown in Fig. 2 would suggest that much of what is still obscure in the line of vascular and muscle physiology may be somewhat cleared up. We know, however, that studies carried out with compression which were not determined quantitatively have shown interesting phenomena with compression sufficient to obliterate the pulse. We have found that the temporary change in the muscle electric curve persisted for some period even after the compression has been released. This would lend support to the views advanced by Lewis and others who have shown that only with moderate degrees of compression can a reactive hyperemia occur. It would seem

as if compression beyond these points was harmful rather than beneficial.

Fig. 1 is a tracing taken from the forearm muscles of a normal boy sixteen years of age. Tracing was made according to the method described above, and as can be seen from the Fig. 1A and 1B is of the monophasic type and positive in character. The blood pressure cuff was placed around the arm and inflated to a pressure corresponding to that equivalent to 120 mm of mercury as recorded on the Mercury manometer. Electromyogram showed the diphasic character seen in Fig. 1C.

Fig. 2 shows an attempt to study experimentally the effect of compression of varying degrees on the electromyographic curve. The method was similar to that described above with the leads over the gastrocnemius and the ankle of the respective limb studied. Fig. 2A shows a positive monophasic curve obtained without compression, the oscillogram is of a normal type. Fig. 2B shows a slight modification of the curve, although it still fails to show the diphasic character present in Fig. 1C obtained during compression. Fig. 2C shows electromyogram of contracting gastrocnemius at a compression of 120 mm mercury, the oscillogram, if anything, indicates a marked increase in amplitude up to six as compared with five and a half in Fig. 2A. At this point, although this degree of compression is still below the systolic pressure, there is a definite decrease in voltage and a change to the diphasic curve described above. This, despite the fact that the oscillogram would indicate no disturbance in the peripheral circulation. In Fig. 2D, the compression of 160 mm does not obliterate pulsation completely, although the amplitude is decreased to four as compared with six in the preceding curve. There is a tendency to increased predominance of the negative type of curve, although the diphasic character still persists. Fig. 2E represents a compression of 200 mm. Although this is well above the subject's normal systolic pressure, due to some compensatory mechanism, a pulsation begins at 124, is most marked between 110 and 70 and still evident although very faint down to 20. The diphasic char-

11

seconds and then was able to walk on. At that time he was smoking excessively which he had been doing for twelve years. Thought cramps were due to pain following application of Lugol's solution. In Spring of 1936 oscillometric examination showed disturbed circulation. Smoking was discontinued for a period of one month, and oscillometric curve showed temporary improvement and heart symptoms disappeared, although they occasionally recurred after indulgence in smoking. In July, he again found it difficult to walk, as a result of a strenuous emotional conflict. Went away for a six weeks' rest and symptoms gradually disappeared so that he was able to walk again. In the fall, he found that he was able to walk considerable distances (six to seven miles). During that period still had feeling of tautness of muscle in right foot. Oscillometer showed a good pulsation and symptoms disappeared completely, for two or three months. Has had no trouble walking approximately five or six miles without any difficulty or cramps. Fibrillary twitching appeared as well as a sensation of tightness in right leg. Tooth was extracted at that time and root got into maxillary sinus which neces-

sitated opening sinus. Sinus was drained and curetted and found to contain granulation and polypoid tissue. Following this, skin grew worse. At times, he still gets twitching in legs while driving. During the last two months this has become more marked. This sensation is present constantly in the right leg, and is mainly below the knees. When feet rest on floor, right leg feels very heavy. These sensations do not lessen with walking. When undergoing an unpleasant mental experience develops an uncomfortable sensation in the right leg as if sitting on a sharp-edged chair. Fig 3 shows apparently normal oscillometric curves in both ankles. The electromyogram of the affected leg is diphasic in character whereas the normal leg shows the normal positive monophasic curve.

CASE 2. E. W. male, aged thirty-one, Russian Hebrew whose occupation is a singer. History of having had frost bite in 1919. At the time both feet were frost bitten the right foot more than the left. Developed an ulcer at the time. It healed slowly and it has left a depressed area close to the nail of the right big toe which is surrounded by thickened skin. He

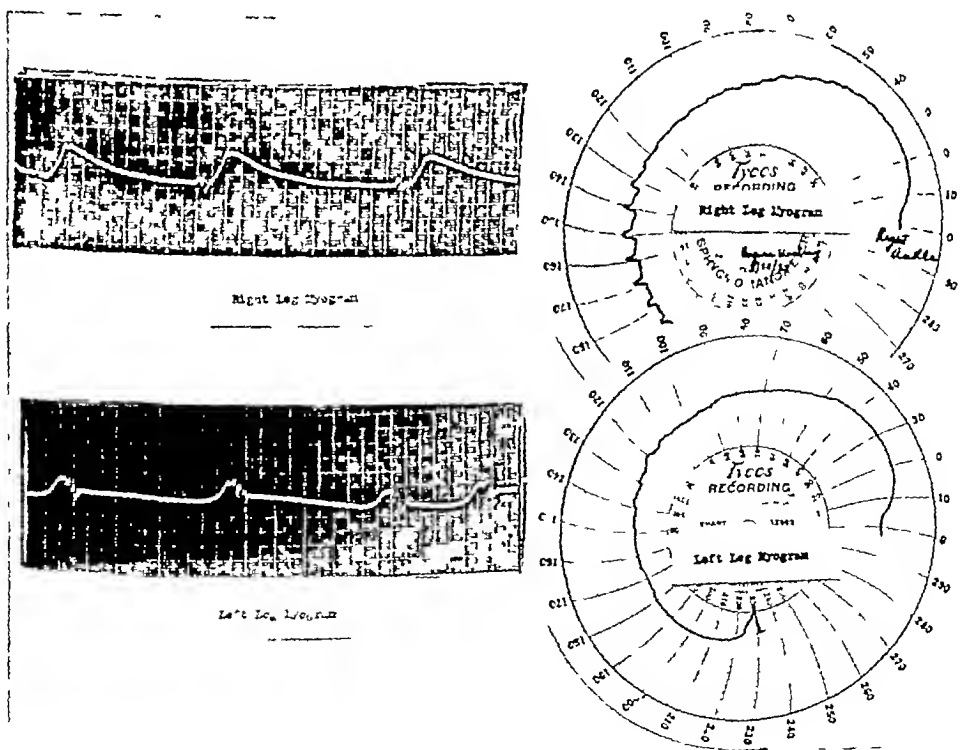

Fig 4

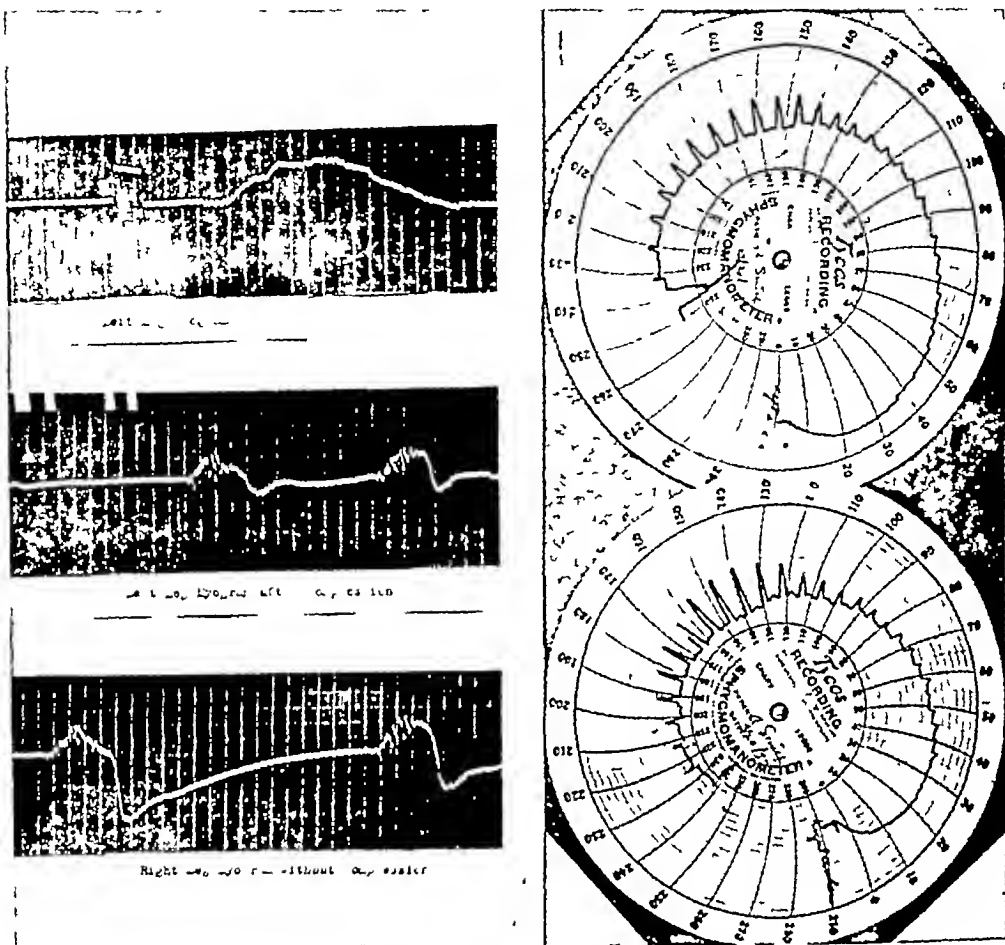

Fig 3

acter is definitely maintained, the curve being also predominately negative. In Fig 2E where the compression of 240 has completely obliterated the pulse, the diphasic character is present with a predominance of the negative type. At this point there are small accessory curves probably induced by changes in the skin circulation. Fig 3 illustrates a clinical application of these experimental findings.

Case Reports

CASE 1 A S, American lawyer, male, age thirty, under observation since January 1936 for allergic condition of the skin persisting for two years. First symptom which he noticed was curling of toenails which developed in the summers of 1927-28 when he was wearing very tight breeches. Since that time, circulation was

not particularly good. Was subject before that to attacks of ringworm which lasted for some time. Cramping sensation of feet (as if arches had broken down) in the fall of 1934 (with a very severe attack of ringworm lasting for several months, treated with Lugol's solution). About March 1936 developed sensation of cramp in extremities, leg and hands, similar to extreme muscular soreness. This feeling was present all the time in both legs, mainly on right aggravated by walking. Twitching of muscles occurred at varying intervals (feeling of bubbling under the skin). Cardiac symptoms became a little more marked and continued definitely at that time. The right leg seemed as if gripped in a vise occurring intermittently, aggravated by mental strain and effort, and physical overwork. Physical effort increased soreness, so that after a while sensation in legs, mostly in right became so painful that he had to stop, would stop for thirty

HUMAN FEMALE STERILITY

Etiological Factors

CHARLES P. SHELDON A.B., M.D., Albany

*From the Department of Gynecology and Obstetrics of the Albany Medical College
and the Albany Hospital*

Dysgenesis is a problem of major importance in American (white) families. It has been estimated that twelve per cent or more of matings prove to be barren, and that in the United States there are 2,000,000 childless couples in the child-bearing age¹⁻³

During the years 1930 to 1935 inclusive, there were 151 admissions to the gynecological service of the Albany Hospital for the purpose of investigating the probable cause or causes of infertility in the female partner of a sterile mating. These cases represent 1.8 per cent of all gynecological admissions during the period under investigation. There were six re-entries, one patient was admitted four times during the six-year interval. One hundred and twenty-eight were under the care of private physicians, as contrasted with twenty-three dispensary cases. Only one patient was colored.

This analysis in no way gives an index of female sterility in the community. A certain percentage of cases are investigated in doctors' offices and never reach the hospital, whereas others go to other hospitals. The great majority of couples never seem to do anything about their misfortune, which is borne out by the fact that 151 cases represent only 0.3 per cent of all admissions to the hospital during the six-year period. Many of those who do undertake an investigation have procrastinated, hoping that Nature will help solve their problem. The marital histories of these cases revealed that the majority had been married five or six years before they were admitted to the hospital for study. Five, however, had been married less than one year.

I desire to express my deep appreciation to Dr. Arthur W. Wright, Pathologist of the Albany Hospital, for much valuable assistance in the preparation of the pathological material.

Approximately one-half (59 of 129) of the cases in which the duration of marriage was known were between the ages of twenty-two and twenty-six inclusive at the time of marriage. The youngest was fifteen, and the oldest was thirty-three. Twenty-four per cent were over the age of twenty-five before marriage. These statistics reveal the influence of the recent economic depression which has contributed toward late marriages and delayed childbirth. Since fertility in the female reaches its peak in the middle of the third decade of life and rather rapidly diminishes thereafter, some of these women may have failed to bear children because procreation was postponed beyond the most favorable time.

One hundred and thirty-six had never been pregnant and were therefore, cases of primary sterility (Table I).

The past medical history was entirely negative in ninety-one cases. Some form of pelvic operation or other therapy had been undertaken in thirty-four instances before the current investigation (Table II).

Rubin⁴ points out the unfavorable influence of appendicitis upon fertility whereby peritoneal adhesions seal the fimbriated ends of the Fallopian tubes, this must be only an occasional factor.

Constitutional defects may have been important in thirteen cases (8.6 per cent) (Table III).

On admission to the hospital sixty-five of the patients stated that their health was normal. In the remainder, nervous symptoms were prominent and in some instances may have contributed to their infertility, but as a rule they were more likely the effect rather than the cause (Table IV).

The principal abnormality in the menstrual histories was irregular bleeding (Table V).

*Read at the Annual Meeting of the Medical Society of the State of New York,
Rochester, May 26, 1937*

noticed two years ago that it was difficult for him to walk without developing a cramp after several blocks. Today he has to stop six or seven times in traversing a wide avenue block. He has noticed a definite difference in temperature in his right leg. His right leg is colder, and he has also noticed recently that his right hand is somewhat discolored when it is allowed to hang down. The right hand is colder than the left. Left foot when in the pendent position turns bluish-red. It is cold, and on deep pressure over the calf muscle the patient complains of tenderness. Patient smokes approximately forty cigarettes a day. The oscillograms taken March 30, 1937 show only a faint pulsation between 140 and 110 (systolic pressure) on the right ankle, and on the left ankle shows pulsation present between 190 to approximately 70, there is an amplitude of about 1.75 mm in the right and 0.75 mm on the left. The electromyograph taken with the technic described herein shows a normal positive monophasic curve in the left leg and a characteristic diphasic curve of low voltage in the right (Fig 4).

Summary

1 A method is herewith presented by

which the electrocardiographic apparatus can serve as an index of normal skeletal muscle function by recording an electromyogram of a constant type in subjects in whom there is no muscle pathology.

2 Compression of the circulation in normal subjects converts the normal monophasic positive curve into a diphasic curve containing both positive and negative elements.

3 This diphasic—i.e., positive and negative curve—is present also in cases where organic or functional spasms of blood vessels interfere with the normal circulation of the muscle being investigated.

4 This method serves as a diagnostic criterion of occlusion of blood vessels in the extremities due to either spasm or disease which may not be sufficient to interfere with the pulsation of the major blood vessels, but which nevertheless is sufficiently intense to produce symptoms.

5 It therefore becomes one of the earliest diagnostic tests of beginning peripheral vascular disease.

GOLDEN OPPORTUNITY FOR RURAL NEW ENGLAND DOCTORS

Through the generosity of William Bingham 2d, a medical center has been created in Boston for the rural physicians of New England that they may pursue postgraduate study at no expense to themselves, reports the *Journal of the Connecticut State Medical Society*.

Mr Bingham's gift makes possible fellowships for a month's work in general medicine at the New England center, together with a stipend of \$250. So-called exchange doctors will be arranged for to

substitute for the absent doctors in their home towns.

Four-week courses were held in October and November and are planned for January, March, and May, 1938. Six fellowships are offered for each of these months. This postgraduate work is under the auspices of the Medical Department of the Boston Dispensary and Tufts College Medical School. All of the instructors are men of high standing and the various courses will be up-to-date and authoritative.

A MEDICAL PUZZLE DEPARTMENT

Detroit doctors who encounter puzzling problems have the privilege of asking advice or assistance from the Counsellor Service of their County Society. Dr C E Umphrey, president of the society, remarks in the *Detroit Medical News*:

The plan is a simple one. If we desire friendly, impartial advice, we are assured that this committee of eight of our fellow physicians stand ready at all times to lend a helping hand. It is only necessary that we write the

Executive Office asking for this service. The office will then arrange for two of our counselors to meet with you on a certain date at the Society headquarters. The meeting will be a friendly luncheon with no minutes kept.

Very often the man just beginning his professional life in our city may have matters grave, perplexing, baffling, that if talked over with an older man would be solved. Under the friendly tutelage, or perceptorship if you wish, one could avoid sorrow, and sometimes catastrophe.

etc., but having regular uterine hemorrhages

It is possible to determine whether a woman is ovulating by examining the endometrium histologically and by differential staining for glycogen just before an expected menstrual flow. Lack of secretory activity at this time indicates the absence of the corpus luteum, which results in a lack of progesterone, the hormone specifically concerned with premenstrual changes in the endometrium.

A review of forty-four cases of this series, in which the menstrual histories are recorded, reveals an endometrial picture consistent with the day of the cycle in thirty-nine, using Herrell's classification¹⁵. Of the remaining five, three had reached the sixteenth, nineteenth, and thirty-second days of irregular cycles without demonstrable evidence of secretory activity in the endometrial picture. One patient was supposed to be menstruating at the time of curettage, but the endometrium was of the late proliferative phase. The fifth case was that of an obese white woman, twenty years of age. She had been married a year and a half. Amenorrhea had been present for six months. Endometrial studies revealed no evidence of progesterone action. At laparotomy, the ovaries were found to contain multiple small cystic follicles. The tunica albuginea was thick, imperforate, and unscarred. This was, in other words, a typical case of sterility due to failure of ovulation in a patient with a primary endocrinopathic disturbance.

There were five cases of oligomenorrhea. In these the expected date of the next menstrual flow was unknown. There was no evidence of progesterone action in their histological sections.

There was no case in this series with a history of regularly recurring, normal menses that demonstrated an endometrial picture consistent with that of anovular menstruation. This probably is only rarely encountered in the human species¹⁶. However, failure of the ovarian mechanism is commonly seen in women with abnormal uterine cycles.

A study of twenty-four cases of so-called functional menorrhagia revealed progesterone action in fourteen. Of the remainder, there was a girl of twelve and

seven women approaching the menopause who gave histories of profuse, prolonged menstrual flow. None of these showed evidence of progesterone action, and in five instances the endometrial picture was that of cystic hyperplasia characteristic of ovarian failure.

In all cases of sterility, therefore, in which a history of menstrual irregularity can be elicited, careful endometrial studies should be carried out to determine if ovulation is occurring. Lack of secretory activity in the endometrium just before the onset of menstruation is the clue to the problem. The fact that it is often difficult to predict this time with any degree of certainty complicates the studies.

Physical findings were of significance in twenty-nine instances. There was a single case with palpable enlargement of the thyroid although five had had thyroidectomies performed in the past and one had been given roentgenotherapy for hyperthyroidism. Only six were considered to be obese. Thyroid therapy in this group of 151 cases would seem to have been of only limited usefulness (Table VI).

Forty-four patients had Wassermann tests but only one was recorded as positive.

It is wise to determine if the patient's health permanently contraindicates pregnancy before becoming too enthusiastic about the cure of sterility. On the other hand, the correction of poor health may overcome infertility and, at the same time, put the patient in such condition that she is physically able to continue the pregnancy.

Sixty-five cases presented nothing of note at pelvic examination. Thirty-six per cent demonstrated some form of local lesion about the cervix. Only five had infantile pelvic organs, which is in accord with the observation of other workers on sterility⁵ (Table VII).

A Rubin test, using air as the insufflating agent, was performed in 136 cases (Table VIII).

Nine of the forty-three nonpatent cases subsequently became pregnant—seven of whom were delivered of living children at term. One patient aborted and another had a tubo-ovarian pregnancy. This indicates the unreliability of insufflation as a means of testing tubal patency. A negative test should be repeated. Lipiodol injection should be carried out on all doubtful cases before expressing a definite opinion to the patient.

Eleven of the cases disclosed findings at laparotomy as shown in Table IX.

The three cases with fibrotic ovaries may have been sterile because of failure of ovulation. In recent years, this factor has been repeatedly stressed as a likely cause of sterility in many otherwise inexplicable cases⁶⁻⁹. Ovulation is said to be absent even though menstruation may be quite normal. This belief was strengthened by experimental studies with the *Macacus rhesus* monkey in which it has been possible to demonstrate anovular menstruation¹⁰⁻¹². Lack of ovulation is reflected in the endometrial picture by absence of secretory changes which are normally seen in the differentiative phase of the cycle. In other words, progestin action is entirely lacking.

Maser and Ziserman¹³ studied women complaining of functional sterility and found anovular cycles in 58.5 per cent. Anspach and Hoffman¹⁴ reported anovular menstruation in 21.4 per cent of women complaining of obesity, sterility,

Meaker and his coworkers¹⁷ have stressed the summation or totality of factors as the cause of human infertility. This study corroborates their convictions. A search should be made for every factor, male or female, which has a deleterious effect on the fertility of that particular mating. In the female local genital disorders play a prominent role, but constitutional defects are equally important. Fragmentary knowledge of endocrinopathic disorders has made this complex problem still more intricate until it is now necessary to subject the partners of sterile matings to the investigations of the urologist, endocrinologist, gynecologist, and internist in order to complete the study of each case and assure them the greatest possible likelihood of successful gestation.

Conclusions

1 Etiological factors in the female partner of 151 sterile matings, investigated at the Albany Hospital between 1930 and 1935 inclusive, have been reported.

2 These cases represent only 1.8 per cent of all gynecological admissions and 0.3 per cent of all admissions to the hospital during the six-year interval.

3 Ninety per cent were cases of primary sterility.

4 Approximately one-half of the patients were between the ages of twenty-

two and twenty-six at the time of marriage, twenty-four per cent were over the age of twenty-five.

5 Constitutional defects may have been important in 8.6 per cent.

6 The general symptomatology was characterized by a high incidence of nervous symptoms.

7 The chief abnormality in the menstrual histories was irregular bleeding.

8 There was only one positive out of forty-four Wassermann tests made.

9 Forty-three per cent had normal pelvic organs, thirty-six per cent demonstrated a local cervical lesion, only five cases had infantile pelvic organs.

10 Out of forty-three cases with non-patent Fallopian tubes, nine subsequently became pregnant. Air was used as the insufflating agent.

11 In women complaining of sterility with a history of regularly occurring, normal menses, some cause other than ovarian failure is usually the explanation for their inability to conceive.

12 In all cases of sterility where a history can be elicited of abnormal uterine bleeding, careful endometrial studies should be carried out to determine if the ovary is ovulating.

13 Prognosis is markedly influenced by the degree of care which is exercised in search for all factors which may have a deleterious effect on fertility.

ONE OF THOSE "INTIMATE" MEETINGS

A disgusted county secretary in another state sent this report of a meeting to his state medical journal:

"The _____ County Medical Society met on the regular date, June 8, in front of Burns Drug Store with the president and secretary only attending. We were con-

servative in our remarks but considerably less so in our thinking about the absent members."

An Ohio medical editor who quotes this wonders if the secretary had sent notices to the members and invited a capable speaker.

ESOPHAGEAL PERFORATIONS

rior wall of the esophagus about two inches from the cricopharyngeus constriction. Here a fine probe was introduced and a tract followed running downwards and outwards for about one inch in length and ending blindly. A small hematoma was found in the extra esophageal tissues between the esophagus and trachea and opposite the esophageal puncture. There was also an air bubble present immediately surrounding the puncture in the mucous membrane. No visible perforation nor foreign body was discovered after a prolonged and careful search.

Conclusions

It becomes evident that such symptoms as subcutaneous emphysema, pain in the back, extreme shock and restlessness, and increasing dyspnea and cyanosis are due

to an esophageal perforation. But these symptoms *per se* are not sufficient to cause death within six hours. I have seen patients with large demonstrable perforations live as long as five to six days and even longer. Acute mediastinitis, the most frequent complication of esophageal perforations, does not cause death in six hours. Most likely the patient had a minute valve-like perforation which permitted a gradual and persistent one-way accumulation of air into the mediastinum with each act of swallowing thereby causing increasing pressure upon the heart and large pulmonary vessels giving rise to the aforementioned symptoms and terminating in death within six hours.

TO SAFEGUARD NEW REMEDIES

The Food and Drug Administration, declaring that seventy-three persons were known to have died as a result of taking the drug preparation, "Elixir Sulfanilamide," has urged Congress to enact stronger drug-control legislation. Responding to a request from Senate and House for a report on the deaths, the administration recommended that Congress

1 License control of new drugs to make sure that they will not be generally distributed until experimental and clinical tests have shown them to be safe for use.

2 Prohibit drugs dangerous to health when administered in accordance with the manufacturer's directions for use.

3 Require drug labels to bear appropriate directions for use and warnings against probable misuse.

4 Prohibit secret remedies by requiring that labels disclose fully their composition.

The administration said that the entire amount of 240 gallons of "Elixir Sulfanilamide" manufactured and sold by the S E

Massengill Company, of Bristol, Tenn., had been accounted for by government representatives working in co-operation with the manufacturer and druggists and physicians who participated in its distribution.

Besides the seventy-three deaths cited, the administration said, twenty other persons who took the medicine died, but it had not been established that the drug was exclusively responsible for these fatalities. Describing sulfanilamide as a "valuable drug" and not responsible for the deaths, the report attributed the fatalities to diethylene glycol, which was used as a solvent in making the liquid "elixir."

"Citations are already in preparation for him to show cause why the cases should not be referred to the Federal courts for criminal prosecution," the report stated, adding that the company had paid fines in 1934 and 1937 for alleged violations of the food and drug act.

FIGHT INFERIOR MEDICINE

Doctors, the time for speculation is over. What we need now is *united action*. We are in the Right. We have no selfish, profiteering motives. We have at stake great Principles, tried and true. Our ordained responsibility is the protection of the people's health. We fight inferior

Medicine. We must stand one great, unified phalanx to defend Medicine from adulteration. We brook no battles, but if there is to be a war, let us be prepared for war, nay, **TO WIN THAT WAR!**—
President Henry E Perry, M.D., Michigan State Medical Society

Case Reports

CASE 1 Chicken bone in cervical esophagus R C, a robust male, thirty-eight years of age, came to the office of Dr Adolph Greenstein on December 22, 1932 complaining of having eaten chicken pie the day before when suddenly he felt a choking sensation and severe sticking pain in the throat. As Dr Greenstein could find nothing by mirror laryngoscopy, he at once realized that the bone must be located in the cervical esophagus. Accordingly, I performed an esophagoscopy under local anesthesia, using ten per cent cocaine to which a few drops of epinephrin solution were added. A short, adult esophagoscope and a bone located about one-half inch below the cricopharyngeus constriction. This was situated obliquely across the lumen and embedded into both lateral walls of the cervical esophagus. Because of its location and position, the bone had to be divided and milked from its bed before extraction was possible.

The patient felt greatly relieved immediately after the esophagoscopy but a few hours later subcutaneous emphysema appeared in the neck—which in itself is not a serious complication and frequently observed following manipulations of the pharynx and upper esophagus. His temperature fluctuated between 100 and 102° F, his pulse between eighty and ninety.

Swallowing improved from day to day and he seemed well on the road to recovery when suddenly, twelve hours before operation and seven days after esophagoscopy, stormy symptoms appeared with extensive swelling and induration of the tissues of the neck which necessitated transfer to the hospital and immediate operation. A large quantity of pus was found in the space between the vertebral column and the esophagus. Drainage was instituted and the patient sent to bed. He expired December 30.

Autopsy was performed and a purulent anterior and posterior mediastinitis was found due to a perforation in the posterolateral wall of the cervical esophagus.

Comment In this particular case the bone, close to one and a half inches in length and sharp on both ends, was found immediately beneath the mouth of the esophagus, across its lumen and embedded into both lateral walls of the esophagus—especially the left lateral. In removing it, the wounded walls were distinctly seen but no perforation was expected nor recognized. The wounded areas were thoroughly swabbed with ninety-five per cent alcohol and the patient instructed to take nothing

but sterile water for the next forty-eight hours. This is just another esophageal tragedy which is encountered occasionally by every ensophagoscopist.

CASE 2 Fish bone in the cervical esophagus N P, a high school principal, forty-eight years of age, presented himself on February 8, 1936 at 3 30 P M with a history of having swallowed a fish bone the evening before. His family physician who accompanied him told me that all day long he had difficult and painful swallowing. Before coming to my office he was examined by Dr A A Schwartz who informed me that he found definite edema of the arytenoid region and adjacent tissues and accumulation of secretion in the pyriform spaces. Mirror laryngoscopy at my office corroborated the above findings. As no foreign body was seen in these regions and as the patient had severe pain on swallowing and pointed to a spot in the lower anterior portion of the neck where pain was most agonizing and acute, I decided to admit him to the hospital at once and perform an esophagoscopy.

Accordingly, this was carried out about 4 30 P M under local anesthesia using a Seiffert type side-ways opening esophagoscope. The mouth of the esophagus was edematous and swollen and so were the arytenoid region and aryfolds. About two inches below the mouth of the esophagus, I saw and demonstrated a toothpick-like projection in the anterior wall. This was seized with alligator forceps but as it proved to be a piece of curled-up mucous membrane it was left alone. Not finding the foreign body, I removed the short esophagoscope and decided to explore the entire lumen of the gullet. The patient, however, became very excitable, screamed, coughed, vomited, and moved his bowels on the table. When he quieted down, I explored the entire esophagus with an adult Mosher esophagoscope but found no foreign body.

About a minute or two following the second esophagoscopy, I found subcutaneous emphysema in the neck and face followed by pain in the back and difficulty in breathing. Later on he became very restless and tossed from side to side. So much so that morphine and other narcotics couldn't control him. An injection of avertin by rectum put him to sleep. But a few hours later he developed stertorous breathing, an irregular pulse rate and marked cyanosis of the extremities. Exitus at 11 30, six to seven hours after the esophagoscopy.

Postmortem by the Medical Examiner the following afternoon revealed a small puncture in the mucous membrane of the ante-

PRIMARY MELANOBLASTOSIS OF THE MENINGES

ISAAC SHAPIRO, M D , F.A.C.P. and ELLIS KELLERT, M D , *Schenectady*

The rare occurrence of primary melanoblastosis of the meninges and its unusual symptoms of subarachnoid hemorrhage, led to the report of this case and a review of the literature

Mrs W D, age thirty-one, school teacher, was referred to me by Dr David Vrooman Her chief complaint was headache, at first limited to the right side of the head, but later became generalized

Past history and family history were irrelevant as far as pertaining to this case

Her present illness dated back to about six weeks prior to admission to the hospital During this period she complained of severe headaches, at times limited to her right occipital region and radiating to the right orbital region and other times the headache was throbbing and generalized She also complained of blurred vision Associated with her headaches, she had attacks of nausea and vomiting The family stated that she was apathetic and had periods of insomnia, alternating at times with periods of lethargy She was forgetful and walked about in a daze She attended to her school duties until three days before her admission to the hospital Suddenly she became overactive, restless, uncontrollable, and uncooperative. Upon examination at that time, she presented a rigid neck, a suggestive internal strabismus There were no other cranial nerve palsies The eyegrounds appeared normal All the reflexes were markedly diminished, but there was a definite bilateral Babinski A lumbar puncture was done and the three tubes contained nonclotting blood and the supernatant fluid was xanochromatic. The cell count was six and the Wassermann test was negative There was no evidence of any Block The remaining laboratory findings were normal X-ray taken of the skull showed no evidence of any pathology A diagnosis was made of subarachnoid hemorrhage, probably due to aneurism of a basilar vessel or tumor

Hospital course She was in the hospital for twenty-seven days At times she became perfectly normal and orientated and at other times, very restless, extremely overactive or very stuporous When she complained of severe headaches, and her pulse was slow, about fifty-two, lumbar punctures were done to release the pressure. Every lumbar

puncture showed either bloody fluids or xanthochromia Finally she became stuporous and went into a coma and expired We were fortunate in obtaining a postmortem examination

Pathologic Report

"There is received a brain which weighs 1575 grams It is symmetrical, the convolutions slightly flattened and the sulci effaced Clinging to the surfaces are small clots of blood which are most abundant over the right occipital lobe The base of the brain is blood stained, the vessels of the circle of Willis apparently normal The entire pia is deeply injected and along the main fissures shows many areas of opacity The cortical vessels are not remarkable and the gyri show no unusual change. The tip of the right occipital lobe is black as though the pia were deeply stained The mesial and superior surfaces are most involved and the black character fades into a brown pigmentation over the adjoining convolutions The cuneus and the gyreis bordering the occipital and paroccipital fissures show the greatest pigmentation

"On serial horizontal sectioning there is found black clot-like material filling the widened sulci of the right occipital lobe One sulcus measures 0.5 cm in width Everywhere the cortical gray matter appears brownish black in varying degree but most pronounced in the occipital, frontal and parietal lobes particularly their lower portions The white matter shows no trace of the pigment. The pia, where thickest, appears most pigmented The velum interpositum shows marked pigmentation, the choroid plexuses none The ventricles are not dilated, their lining surfaces are smooth and pale The third ventricle is filled with gelatinous blood stained material The basal nuclei appear normal The substantia nigra in the pons is normally abundant and distributed The pons, medulla and cerebellum appear normal

Microscopic Description

"Sections from various portions of the brain including the vertex and base show greatly thickened meninges infiltrated by tumor cells In the right occipital lobe the growth is abundant, very cellular and pig-

Read at the Annual Meeting of the Medical Society of the State of New York, Rochester, May 25, 1937

ta anterior. In rare cases, even the convexities of the brain are pigmented, but always in the sulci, not upon the gyri.

The forms of pia melanophore cells are manifold, and their sizes are variable. They contain various amounts of pigment of different colors. The pigment granules of blue-eyed individuals are lighter. A study of the relation of pigment to age shows that the pigmentation develops after birth, appearing first where the medulla oblongata continues into the spinal canal. During the following years, typical localization of the pigment develops. In older individuals, it seems that the pigment production ceases. The pigmentation of the iris is in direct proportion to pia melanosis, but the pigmentation of the skin is not. There is no disease in which an increase of the pia melanosis has been observed. It is these pigment cells that are important pathologically, because they may be the origin of melanotic tumors.

Comparative anatomical research shows that pia melanosis differs in man and in animals. The difference can be explained

by the bodily position and posture in man and animal. It cannot be stated whether pathological conditions of the brain have any effect upon the pigmentation of the leptomeninges. There is a certain relation of pia melanosis to blood supply, but it is not characteristic. The localization of pigment is not determined by vascular arrangement but by mechanical factors.

There are considerable pia chromatophore cells in places or sites where there is stagnation of the cerebrospinal fluid, especially in the recessus of the meninges, and also where the contact between the cerebrospinal fluid and pia is firm. A chromogenic substance in the spinal fluid might explain the whole picture of pia melanosis.

It was Virchow² who described the first case of melanosarcoma of the meninges. Since then Thorel, Grohl,³ Foote,⁴ Boit,⁵ and more recently Farnell and Globus,⁶ Winkelmann⁷ and Netherton⁸ have described primary melanotic tumors of the pia.

It is not unusual to find metastatic

Fig. 3 (A) Tumor cells crowded with dark brown pigment granules. (B, C) Tumor detail. (D) Tumor growth about vessel in cortex. (Photomicrographs X-400)

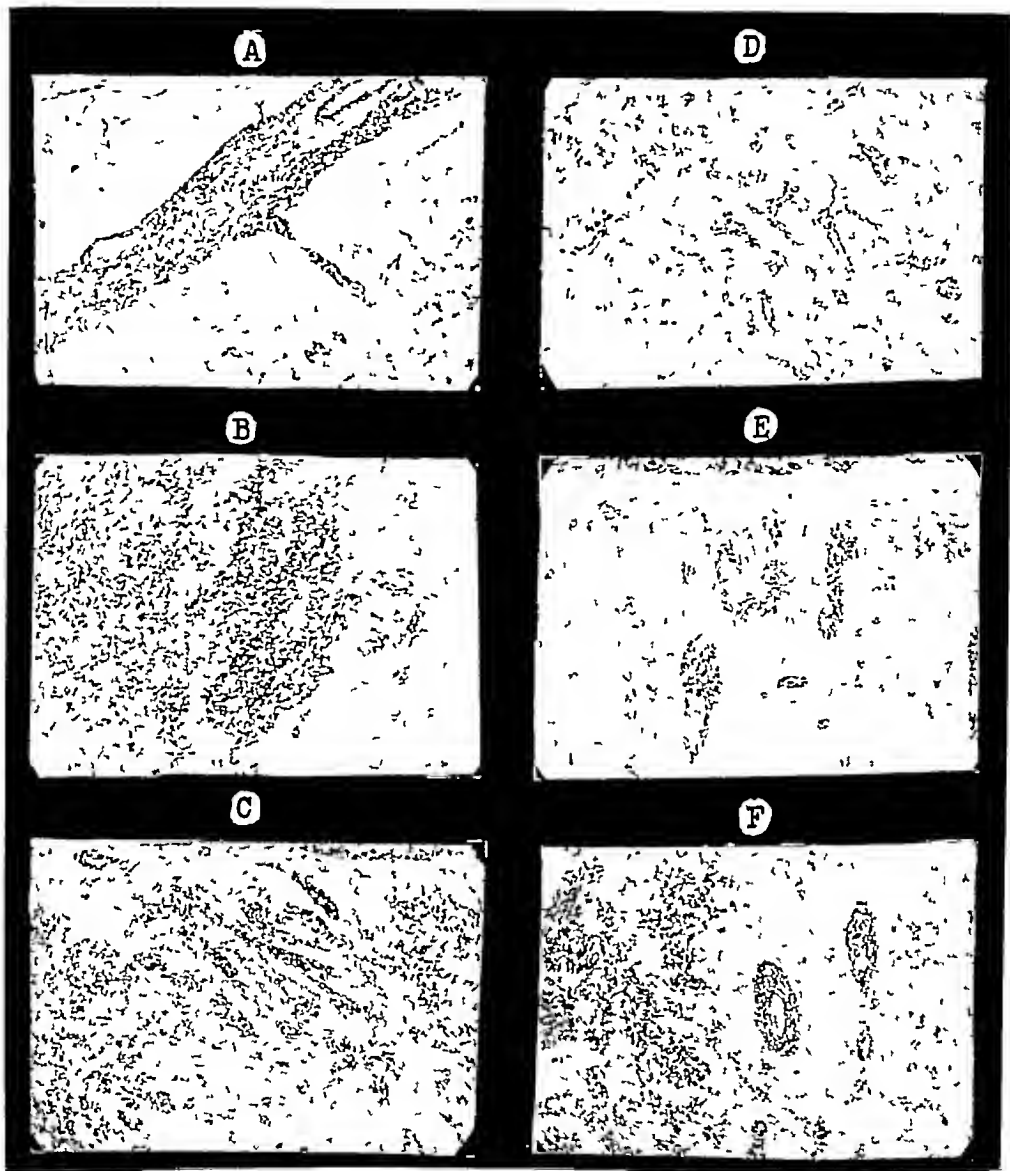

Fig 2 (A) Meningeal growth extending into cortex (B) Meningeal growth of occipital lobe invading cortex (C) Tumor growth in deeper layers of cortex following the vessels (D) Tumor in superficial layers of cortex (E-F) Tumor cells forming "cuff" about vessels (Photomicrographs X-100)

cerebellum covers the oblongata, they are absent around the median aperture of the fourth ventricle. Below this, pigment cells are regularly present. The borderline between pigmented and non-pigmented parts is very sharp, often resembling a V. In the region of the decussation of the pyramids and posterior the cells are more on the lateral aspect of the oblongata. In the spine, the most pronounced pigmentation is around the departure of the anterior and posterior

nerve roots. The pigmentation is especially marked on the cervical and lumbar bulbs of the spine, where the pigment cells have fusiform shape and possess two projections.

In the pons the localization of pigment is not uniform. It is absent in thirty per cent of the cases. Pigmented cells are found about the optic chiasm and is extended over the optic nerves. Marked pigmentation can also be found between the optic tract and the substantia perfora-

Preventive Medicine

"Cut-Out" Infected Wounds

CHARLES H. GOODRICH, M.D., Brooklyn
Presidential Address

This "cut-out" is metaphorical. What we stress today is the prevention of ordinary casual wound-infections and operative infections which now cause much temporary and permanent disability and a certain percentage of deaths. We have no discoveries to announce except that we do not prevent enough infections and that the general public takes it for granted that they know all about diagnosing and treating casual wounds until someone dies or is considerably or permanently disabled. Then, or at least late, they go to the physician who suggests "Why was I not consulted the wound's day and hour?" The reply "I did not know that you could do anything more than I did—I put iodine (or mercurochrome) on it *very* carefully and the wound was so small." That "I did not know" is the horsefly in the ointment. They read an irresponsible paragraph in a tabloid, a newspaper or magazine—and only half of that—and presume they are surgically equipped for any traumatic emergency. Many people know *some* principles of first aid—but we find their greatest interest in stopping bleeding—sometimes managed quite efficiently—or too efficiently.

During our campaign for preventive medicine it is well for us to recall the cardinal principles of wound treatment and pass them on to our people. To them we might also suggest that carpenters and masons build better houses, engineers are better at the steam-plant or on locomotives, and cooks are more efficient in the kitchen than physicians would be, and conversely that physicians trained in anatomy, physiology, chemistry, bacteriology, pathology, diagnosis, and medical and surgical therapeutics will do better work in preventing wound infections than said carpenters, masons, engineers, and cooks.

As we review first principles we can put them in order and be ready to instruct the increasing army of the health conscious,

with the expressed reminder that there is a distinction to be drawn between soiled wounds and infected wounds. Infection is a sequence of the soiling. The interval between reception and treatment is most important and the shorter it is the better. The essentials of wound treatment are

- 1 Cleansing and disinfection
- 2 Control of hemorrhage
- 3 Careful examination
- 4 Accurate restoration
- 5 Effective protection
- 6 Physiological rest

1 *Cleansing* the wound and a *generous area* thereabouts is indicated. Something that will eliminate dirt should be used, for example soap and water, or benzene especially if dirt is oily or greasy, then alcohol or ether also grease solvents and dehydrators of watery dirt. Then *not carefully* but freely, 3½ per cent iodine should be poured or "swum" into wound or applied with a swab. If wounds are extensive, such treatment can be made comparatively painless by the introduction of 2 per cent novocain pack after the method suggested by E. K. Tanner. (This is especially happy in its application to the large lacerated wounds associated with compound fractures.) In recent years some surgeons have limited the application of iodine to the skin and use copious irrigations of saline, boric acid, boro salicylic, or Dakin's Solutions in the subcutaneous defect. We admit that this method, which we used enthusiastically thirty-five years ago, afforded good results. Also we wore rubber boots in the operating room instead of the tennis shoes of today.

2 Absolute control of bleeding within the wound is necessary for prompt primary healing. Blood is the ideal culture medium and in any form aids infection's rampages.

3 Careful scrutiny of depths of cleansed wound is necessary to ascertain if there exists foreign body or injury to deeper tissues (tendons, bones, joints, serous cavities, viscera). In case of such findings, special treatment is necessary.

4 The wound defect is closed by sterile sutures or clips, or rarely, in small skin wounds, by sterile adhesive strips.

nodules in the brain secondary to a primary lesion elsewhere, but one rarely sees secondary involvement or extension of the tumor to the meninges. In this case and others quoted the lesion seems to be limited to the soft membranes with slight or no involvement of the adjacent brain substance.

It is interesting to observe how this tumor encircles the whole brain, being more marked in the sulci and at the base. The extension of this tumor throughout the leptomeninges is possible, if one accepts the following theories:

First, that the tumor arises in the soft membranes because of some glandular disturbance.

Second, that the tumor is metastatic from some other source not recognized.

Third, that the tumor arises from a group of melanophore cells, and extends throughout the subarachnoid space.

Much has been written in recent literature in regard to the role played by the pituitary, especially the pars intermedia in the formation and production of melanin. One would expect therefore a disturbance of the melanin production throughout the body.

The types of cells and its extension throughout the meninges and within the cerebrum is characteristic of neoplastic disease and, since there was no other source found, we must accept the primary formation of this tumor within

the leptomeninges, knowing as we do of the presence of melanin within the soft membranes.

Many pathologists feel that the melanin is a mesodermal pigment—almost analogous to the nevi of the skin. There is still considerable confusion as to whether the meninges are entirely ectodermal in origin or mesodermal or both.

Summary

The case presented is that of a school teacher with all the characteristic symptoms of subarachnoid hemorrhage. Upon postmortem examination a primary melanoblastosis of the leptomeninges was found. The tumor had invaded a pial vessel in the region of the right occiput and produced the subarachnoid hemorrhage. The literature is reviewed and there is considerable discussion about melanosis of the pia mater and its frequency and occurrence in the normal brain.

Discussion

DR VICTOR C. JACOBSEN, *Troy*—The difference in opinions regarding the origin of melanin-bearing cells is due to the fact that these cells have been found in almost every part of the body, either incidentally or as the primary source of neoplasms. This natural dissemination of chromatophores has been given far too much significance in explaining their origin. Are not nerves and their end-organs just as widely distributed?

Dr Shapiro's patient illustrates the meningeal origin of melanotic tumors and pathways of spread, directly into the brain and via the cerebrospinal fluid. The proximity of the tumor to the brain is a circumstance favorable to the idea of a neurogenic origin of the tumor cells. It is not necessary to demonstrate nerve filaments among the cells to suggest their probable neural source for nerve fibers are

the product of the more mature neuroblasts. The term "chromatophore" signifies only that a cell carries melanin, while a "chromoblast" or "melanoblast" not only carries the pigment but also makes it. Perhaps cells other than those derived from neuroectoderm can make melanin but until histopathologists are more careful in distinguishing between the genesis and the phagocytosis of melanin the present confusion will persist. Phagocytosis is a property of cells from all three germinal layers, but the formation of melanin is probably a characteristic of only one layer—the ectoderm.

The ability of the tumor cells in this case to spread in the subarachnoid space suggests that sooner or later a correct diagnosis will be made by finding the cells in the spinal fluid, just as in the case of medulloblastoma for instance.

PREVENTIVE MEDICINE

Number 241

(The skin test to prevent anaphylactic shock should always precede the injection of Tetanus Antitoxin)

Gunshot flesh wounds when single or discrete merit all of the attentions given to punctured wounds including antitoxin even if bullet has passed in and out of tissues. Wounds of ingress and egress should both be treated. In addition special attention should be given to possible injury to large blood vessels, nerve trunks, and tendons. When bullet wound is of head, neck or trunk the earliest possible diagnosis and treatment by a physician and surgeon in a surgically equipped room—preferably in Hospital—is so generally deemed urgently advisable that little exhortation of public is needed. We have seen such wounds two and three days old upon admission to hospital where gangsters, foreign secret societies, and would-be suicides were involved.

In gunshot wounds of head, neck or trunk the greatest care must be taken by us to determine whether or not there is (1) Injury to a major blood vessel, (2) Injury to an important nerve trunk, (3) Penetration of a body cavity (including spinal canal) (4) Perforation of a viscus (including spinal cord), or (5) Gunshot fractures

Incised wounds the "clean cuts" of the day nineties, if superficial, are easily disinfected, examined, and cared for with assurance by the correct application of our six cardinal principles. If the incisions sever muscles, tendons, or nerves or penetrate a body cavity we are again practicing major surgery—preferably in a hospital operating room.

Contused and (or) lacerated wounds offer special opportunities for service. Their variety in design, concavity, convexity, and extent seems unlimited. From the bursting bruise with opening so small that it does not provide for the outflow of subcutaneous bleeding and so requires incision to control hemorrhage, to the long and broad tearing of tissues due to falling against a sharp projection or being dragged after such a projection has taken firm hold in flesh. Contused and lacerated wounds are often coexistent from the same injury. Most are apt to be "dirty" macroscopically or microscopically or both. All of the six cardinal principles heretofore mentioned must be applied, usually plus anti-

toxins. In addition tissues (especially skin) are frequently so evidently damaged by compression, laceration or shredding as to assure their necrosis or gangrene. This calls for "debridement" or cutting away of tissues so damaged in order to disinfect neighboring or underlying structures and (mainly) to do away with food for the riotous debauches and development of bacteria rubbed into them by the mechanism of injury. Proposed about thirty years ago, this "debridement" was *proven* during the World War. Often accurate restoration by suture is thereafter difficult or impossible. If difficult we must remember that stitch tension can strangle and kill tissue and we may recreate the conditions we seek to avoid. If impossible, sterile drains should be used where sutures cannot be placed. If a large concavity or exposed surface must remain a light fluffy packing (surface-dressing of absorbent gauze should be applied. This dressing should be of sterile vaseline gauze or a wet antiseptic gauze to minimize tearing away new granulating tissue when it is removed. Over all in most of these cases a copious continuous wet antiseptic dressing is usually in order. Complete disinfection of such contused and (or) lacerated wounds is always doubtful however meticulous the care at the original dressing or operation.

One word of caution regarding phenol and its derivatives. Distal portions of injured extremities should never be completely enveloped in dressings saturated with carbolic, Lysol, creolin, or cresol solutions, etc., especially in older patients and certainly not for more than a few hours. Important degrees of death of soft tissues have thereby been caused and may result in any case. To complete the reference to contused and lacerated wounds it is hardly necessary to mention that some of the most serious are associated with compound fractures where the fragments of bone as well as the traumatizing agent are responsible for soft tissue injuries. "Debridement" of bone is often indicated to a limited degree and prophylactic antitoxins are here always in order (tetanus and perhaps gas-gangrene or antistreptococcus). In crushing wounds as well as much soiled contused and lacerated wounds the serum for the gas gangrene is not efficient as a preventive measure but does

5 The surgical field thus cleansed and "disinfected" should immediately be isolated from the rest of the world by a dry sterile gauze dressing of generous thickness, sterile cotton pad, and a firm but not tight bandage. This dressing may be left in place from one to ten days according to local and general symptoms and objective findings. Overfrequent dressings are meddlesome and sometimes harmful. When much tissue damage is evident and reactive tumefaction anticipated, a cold wet antiseptic dressing may replace the dry one, such as Thiersch's borosalicylic, aluminum acetate, mild phenol or Lysol solutions, or acriflavine, Metaplien or some other modern well-advertised and approved affair.

6 Physiological rest for days or weeks is the sixth great principle, and whatever is needed to bring this about may be used. Ordinary bandages may be supportive enough in minor instances, but light splints, starch or plaster bandages, or adhesive plaster are resources of value.

There they stand—six simple principles, all in the physicians' primer—all ready for beneficent use on call.

- 1 Cleansing and disinfection
- 2 Control of bleeding
- 3 Intelligent examination of cleansed bloodless wound
- 4 Accurate aseptic closure (in layers if more than one are severed)
- 5 Adequate protection for seven to fifteen days or more
- 6 Physiological rest for as long as necessary to promote healing

How many laymen can perform these duties with assurance of success? Is not the examination and diagnosis of unlimited importance? "But" they say "some wounds are so small." "Right" say we "So are the leaks in the pipes that carry carbon monoxide to the motoring victim's lungs. So are the bites of the 'yellow fever' mosquito and the anopheles family. The size of the 'infection-atrium' or gateway does not proportionately enlarge or minimize the danger of infection! 'Infection-atrium' was indelibly impressed upon us students by Surgeon Robert F. Weir at Columbia's College of Physicians & Surgeons. Over and over again he repeated it on scores of occasions. 'Infection-atrium,' until the time-unguarded gate providing a break in the protective wall of an ancient metropolis. Thus the small size of the wound should not be regarded as assuring freedom from infection. We might as reasonably disregard the

potentialities of the spermatozoa because of its size. Some spermatozoa die ineffective. Some small wounds heal without care. Count all accomplishments of both and our respect for small things grows.

While we speak of small wounds we will start to modify or embellish our six cardinal principles in accordance with the types of wounds.

Punctured wounds, and especially those produced by the penetration of skin or mucous membrane by pins, needles, tacks, thorns, wires, nails, slivers of wood or metal, rake-teeth, and similar objects deserve special attentions. Such more or less pointed objects often carry through the skin and into connective tissue spaces or muscles minute fragments of dirt, clothing, grease, or other infected material. When the puncturing missile is withdrawn through stretched skin the elastic fibers in the skin contract, the wound closes or nearly and the bulk of infecting material is left inside provided luxuriously with culture media and animal heat, so that a splendid spree is promised for all. Here the pyogenic staphylococci and streptococci most commonly revel and less frequently but commonly disport the anerobic bacilli of tetanus and gas-gangrene. These bacilli which flourish only in the absence of oxygen call for a special consideration of punctured wounds. Some surgeons urge invariable laying open the wound by incision or excising it, investigating its depth for foreign material, always disinfecting as in other wounds. Peroxide of hydrogen should be injected or swabbed into such wounds because of the probably mortal effect of nascent oxygen upon Bacilli of tetanus and gas gangrene. In a series of 123 cases of Tetanus reviewed by us in 1898 three were caused by rose-thorns, one by a sewing needle, eight by wood splinters, one by a pick, one by a pitchfork, twenty by nails.

In addition to some special form of treatment for punctured wounds prophylactic tetanus antitoxin should be used in all punctured wounds and all other dirty wounds of depth. This is pre-eminently important where geographic area (as most sea coasts and all of our Long Island) is known to be crowded with Tetanus Bacilli, or when wound is received in some place where dead or effete animal matter is widely distributed as in battlefields, barnyards, horse stalls, garbage dumps etc.

PREVENTIVE MEDICINE

December 15, 1937]

balanced in kind especially for bed-patients. We wonder if bed-patients should ever have the prevailing "full diet" except when they are profoundly septic. Then of course, they must be carefully and studiously overfed.

How is the heart-action? Is stimulation needed to bring it up or down to normal? Are you in doubt? How about an electrocardiogram? An effective "engine" is a real ally in the fight for wound repair. What about blood pressure? Watchful observation and regulation will assist in balancing circulatory forces. Well-balanced circulation may at times determine the success of wound repair.

Is there acute anemia from hemorrhage or a previous anemia increased by trauma? Ideal transfusion is the surest reinforcement.

Is there gastrointestinal fermentation or putrefaction? Are alkalis indicated? Or dilute acids?

How does colon behave? Be sure of adequate evacuation daily without depletion. Have we exposed this patient to whatever available laboratory measures are needed whether biochemical, bacteriological, or roentgenological?

All these matters and more have to do with the prevention of wound infection, or efficient early treatment which is realistic prevention.

Much of the routine thought suggested may be unnecessary in the care of so-called "trivial wounds." Yet how are we to determine "trivial wounds" until the final result is known? A well-known otolaryngologist pricked his thumb through a sterile rubber glove with an unused sterile (?) tonsil-snare wire *before* using it. A vicious streptococcus infection followed—pus was obtained from an incision in tactile cushion of thumb in thirty-six hours and during the following weeks sixteen incisions with drainage were made in hand and forearm until the heroic patient during a dressing remarked "with all those tubes it looks like a battle ship!" "Trivial wounds" indeed! And yet there are many wounds which apparently uninfected, heal "perprimam" sans attention. Assume that this happens in thirty or forty per cent of all wounds—a liberal assumption—is that any reason for failing to abolish infection in as nearly 100 per cent of wounds as is humanly pos-

sible, perhaps ninety to ninety-five per cent? Ethically, has any person, whose relations to home and community are normal or better, any right to take a thirty per cent chance in the treatment of wounds when he could avail himself of ninety per cent?

Uncommon types of wound infection such as anthrax, glanders, tularemia, actinomycosis, hydrophobia and rat-bite fever must be deemed important because of their comparative rarity and the special knowledge concerning etiology and prevention to be kept in mind ready for use.

A prize-fighter displaced the teeth of his syphilitic opponent thereby wounding his hand. The victor became a victim! Syphilitic wound infection is uncommon but very tragic! Perhaps most common among physicians! The current war on syphilis and the free use of iodine in wounds especially of the hands are preventive measures par-excellence. In the above instance if a careful history had been taken of the other fighter this might have helped—if he had told the truth! How often can this be done? Stamp out syphilis and fill wounds with iodine! This will answer in due time.

Tuberculosis enters neglected small gateways sometimes especially during childhood and youth. Parental attention to the "scratches" and "bruises," often disregarded, may spell prevention in capitals. Cleansing, a penetrating antiseptic (preferably iodine) and an occlusive dressing are the least we can do in justice.

A current commentator on our national foreign policy has remarked "We are afraid to defend Liberty lest liberty be lost. And out of the fear of war we prepare ourselves to accept the worst things that war can bring" (Dorothy Thompson, *N Y Herald-Tribune*, Sept. 9).

Reapplied to our scientific problem this reasoning might read "Are we afraid to treat wounds because then they might not heal kindly?" And while we fear wound infection should we prepare ourselves to accept the worst things that wounds can bring? If not, meticulous prevention of wound infections is as rational as it is effective—a wise policy throughout the world.

All praise to the many surgeons who through the years have systematized, simplified, and rationalized the preventive treatment of wound infection!

lessen severity of disease. Also if discovered early the serum is often of value therapeutically. Where gas-gangrene is feared frequent smears and cultures of crushing wounds beginning eight hours after injury will show presence of bacillus *Welchii* before clinical signs are apparent (Callender). At times the discovery of bacillus *Welchii* is difficult. A recent method provides for the making of stab cultures from wound which, if they "take," develop gas bubbles in twenty to forty minutes.

In considering wounds made at a planned clean surgical operation, we report that a recent review of literature from numerous United States clinics records an average of ten per cent infected wounds in so-called "clean" operations. In this day of rigorous preoperative preparation of the surgical field and highly developed technic of closure and postoperative care this high incidence in various clinics is surprising. It should readily be reduced one-half or one-third of this figure. Here the main additions to our six cardinal principles (and always important when these are being applied) are the thorough five to ten minutes scrubbing of hands and forearms, and the use of sterile rubber gloves on the part of the surgeon and all assistants. Sterile instruments are always surgical necessities. Gentle handling of tissues even if more time is used, for we thus minimize opportunities for infection. The dangers from prolonged anesthesia are minor compared with those of rough handling. "Relentless stretching of wounds by retractors," "inadequate protection of wound edges," careless hemostasis, "unsuitable ligatures of sutures" in material or size should be avoided and the scalpel which severs skin should never be used in deeper layers.

Crowds in operating rooms especially visitors not properly equipped may cause infection. Meleney and Stevens once found that one-third of operating room personnel were hemolytic streptococcus carriers. Cultures of operating room air and equipment should be taken at regular intervals, and unsuspected plumbing connections between tap water and sterile water pipes have been demonstrated (Methodist Episcopal Hospital, Brooklyn).

The operative field should be carefully shaved and then prepared as was the wound and its field under "cardinal principles."

Many substitutes for iodine are suggested as skin disinfectants. We prefer iodine (3½ per cent) because along with its use we have had less than average minimal wound infections. We also like the brand of catgut and sutures we use for the same reason (and others) although some surgeons do not like the "smell" thereof. We like our chauffeur for his results regardless of the fact that some folks wonder if he is "white, chinese or a colored gem'men." Why should we abandon iodine because of "smell" or color any more than we release our catgut for odor or our chauffeur because of color? Others may find results from varying skin disinfectants as good as iodine and be as content as are we. God bless 'em and good luck! There are occasions when the skin in the particular individual or region seems extraordinarily delicate or in certain plastics where we desire as colorless a field as is possible. Then we clear the color, not the bactericidal effects, with ninety-five per cent alcohol.

When our wound has been protectively dressed, forces innate in the person under our care proceed to the duties of repair. The completeness of this accomplishment depends upon physiology, which is "the science of the working of the healthy human body." How many subjects are "healthy" after receiving wounds in accidents, in battle, or in operating-rooms? It is our business to find the delinquent spots in the complex mechanism, and fortify them as best we may in order to *promote tissue repair and resistance to infection*. For our local success in banishing infection cannot safely be assumed to be absolute or invariable. Rather it is occasional, and otherwise approximate in degree. Therefore security in repair and more complete resistance to infection demands our attention to all vital functions and especially to prevent dehydration and malnutrition which may have existed before, or hastily supervened the wound event.

Fluids may be administered by mouth, by proctoclysis, hypodermoclysis, or intravenously. Sterile tap-water, saline, sodium bicarbonate or glucose solutions may be used according to indications. Major wounds of almost all sorts need fluid fortification.

Nutrition should be more than normally adequate in calories and vitamin value, and yet food should be simple and well-

completely ignorant in child up-bringing. He was their first child and they had blundered ever since the day of his birth. They did the usual and the expected they "spoiled" him—a correct and descriptive term.

Maybe I might have had no trouble with Georgie if he had been a mental patient only. But there were other complaints also and he looked pale and underweight and his posture was bad.

So, after a preliminary talk which yielded nothing, as the boy would not answer, the parents asked him to undress himself and as he refused, they proceeded to undress him. It was difficult. He kicked and fought them all he could. When it came to dress again he opposed them even more vehemently—and with more success.

He was told that now he can go home. But he was enraged and revengeful and would make no concessions.

Therefore, I asked the parents to leave the office for about an hour. This was something unprecedented for them and they did it only out of respect for me. They went out into the street and I called in another patient who happened to be a man of seventy-five with a white beard, whom I asked whether he would mind Georgie's presence. He said good-humoredly, "Not at all" and I began to examine the old man.

As we paid no attention to the boy, he stopped crying, dressed himself completely and very well, and wanted his parents. I told him they had gone out for a walk. Meanwhile, as I was through with the other patient, I began to talk to Georgie. This time, *in the parent's absence*, we soon became friends and, when they returned, they were greatly surprised to hear him laugh and play ball with me in the most enthusiastic manner, which did not keep him from starting to cry as soon as he saw them.

These parents had thought that the child was *mentally abnormal* and so had the teacher in school, where Georgie was a

nuisance. Indeed, *that could have become a fact*. He would not play with anyone during recess. He often disturbed the class by talking loud to himself, with utter disregard for anyone else.

He was extraordinarily "stubborn." There is nothing intrinsically wrong with stubbornness. It may be a quality. It depends to what use it is put.

But Georgie, a child with normal intelligence and even with an IQ somewhat above the normal, with no organic defect, although suffering from general physical debility which, by the way, was remediable, really was *on the verge of some mental waywardness and unsteadiness*.

The second time I saw Georgie he behaved in an entirely different way. And, without going into details, I wish to assure my readers that he gradually changed.

However, the chief treatment was not administered to him, but to his parents. They were shown how grave their errors were and told how to modify their conduct toward their little boy, which they did.

There was no need of much teaching. As soon as they were convinced about the right road to follow, they made it their business to reform their relations with the child completely and fundamentally.

Any medical thinker should be able to perform the same "miracle."

However, in spite of my experience with children, there are cases, although happily rare, where I fail. My best friends among them are those who had come before as healthy visitors accompanying their sick parents, which happens quite often. Then a lasting friendship is established and the ground for confidence is laid for the time of need. One of them, three years old, when told not to run into the street where he can be killed by a car said "That's nothin', the doctor'll fix me." Meaning the author. Another boy of five also asked his mother seriously to send for me in an emergency when the plumbing was out of order.

LAY VIEW OF STATE MEDICINE

A lay reader of a New York newspaper is stirred by reports of coming health insurance bills in Washington to "write to the editor," and say

"I believe in medical and dental care for the masses, but I do not believe that those who have observed the health rules and have reached the higher income brackets

should be taxed to pay the hospital and doctor bills of the alcoholic, the syphilitic and those who give no thought to their health until they are ready for hospitalization.

"Since efficiency is so clearly related to health, the more efficient will have to pay the higher tax while deriving none of the benefits."

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., DR.PH., New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Stubbornness

I usually get along with children who come as patients

Even if they are ill-prepared and frightened, either from previous bad handling or because they have been threatened and scared by their foolish parents, they mostly go home smiling and happy. No matter how fiercely uncooperative they are at the beginning, they soon become reconciled. There have been many cases where our relations were so cordial that the children did not care to leave the office and they sent the parents home.

What are my methods? I do not know myself. I have none. I am just chummy with the children.

I talk to them. I play with them. I show them something interesting.

I give them toys—"for keeps." But I never give them anything when they are "bad." Of course, in home-upbringing bribing, even preventive bribing, is a mistake and no one should resort to it. But in the doctor's office, where there can be no question of observing the real principles of proper upbringing, and where there is no time to lose, we must be permitted to deviate from our own rules. By the way, I avoid giving them mouth-toys like whistles which may spread infection of some sort by promiscuous use. And I never hand them candy or other foodstuff in order not to interfere with the parents' feeding plans.

I familiarize them with the stethoscope by letting them touch it or by showing them how it does not hurt the mother when it is applied to her chest. Of course, the tongue depressor is the first gift they get. And they often "need" one or two more.

They are free to roam around and ask questions. They frequently want to know where I sleep and whether and when I eat. All that goes for all ages, from a few months to six or seven years. Later they may be treated as adults.

I never lie to them. I always keep my promise. I tell the older ones in advance when I'll have to hurt them and appeal to their bigness and heroism.

I do not tolerate the parents' camouflage—"this is not a doctor, but an uncle." For some children their uncles may be worse than any doctor and I must reject the comparison. Why not admit that we are doc-

tors, but claim that we are good and prove it to them? Besides, the child sees the bluff. Unless he is an idiot we cannot fool him.

I rarely have any difficulty in examining a child. But if I do meet with opposition I am quiet and determined and do my work—regardless. I never become excited or lose my temper or my smile or the gentlest sweetest voice of which I am capable, adopted from the beginning. The child becomes finally convinced that my intentions are good and sees that I do not hurt him. If the only way to break his resistance is by hurting the child, I prefer to give up or postpone the examination.

Not only during my examination do I avoid violent motions, but all through the session in which the child is present I am careful not to be brusque. Would I try to catch a cat by running fast toward it? No, I would only scare it away. This behavior is particularly required when dealing with the smaller children those under four.

The proper tact in the relations between doctor and child-patient is not only important for facilitating a physical examination. It often goes a long way both to improve the child's mind and to educate the parents—and so it may help to prevent or cure troublesome mental states. It belongs to good psychology and correct preventive psychiatry. It will even repay from a practical point of view. The child will prefer the physician who treats him nicely and will refuse to visit another one.

If it is necessary to handle children rightly in the cases of physical ailments, it is even more important to do so when the complaint is mental when we deal with a problem child, a behavior difficulty, a maladjustment or an unusual family situation. Our first approach may not only help us win the child over for cooperation and form the basis for a cure or may even be the beginning of the cure.

Still, I cannot say that my experience has helped me in my first meeting, or rather clash, with Georgie, seven—at least not until that encounter was almost over. He was brought to me by his father and mother, pleasant and intelligent people, but

Three years ago, Dr Conant, the President of Harvard University, called attention to the dangers to our government from "social leadership" which would wreck our democratic society, because of ignorance, or because it blandly and innocently would "send to the scrap heap institutions, traditions and even principles which, if they are not absolutely fundamental, are integral parts of the whole fabric of our form of civilization"—to accomplish the establishment of their pet schemes.

The law and tradition among us heretofore has been, that Congress shall provide money and determine the scope of its expenditure, and *no one else*. This is one of the fundamentals of our government. Anesthetized, with fears allayed, our citizenry seems strangely apathetic to what is happening to our government.

"Citius venit periculum, cum contemnuntur"

Proof of the Pudding

The best argument for or against any system is how it works. No amount of theoretical "shoulds" can gainsay an actual "doesn't." Judged by the strict rule of results, the principle of free choice and free competition among physicians has conclusively demonstrated its superiority to the project-doctor system in the United States Works Progress Administration for New York City.

Prior to March 1937, the WPA in Greater New York employed its own physicians for workmen injured in its service. At that time, at the urging of organized medicine, it switched to the panel system in force for workmen's compensation in this state. Results were immediate and striking.

At the end of three months, John F Overend, the State Compensation Officer for the WPA, found that the operating costs of his department had dropped almost eighteen thousand dollars a month. The net saving to the Federal Government, allowing for the heavier burden upon the Federal hospitals as a result of

the panel system, was over nine thousand dollars monthly.

"A matter that is probably of more importance than the economics involved is the fact that injured employees are receiving better medical treatment than heretofore. The average panel physician is more skillful and experienced, he manifests a greater interest and care in his patients, the injured employee has more confidence in his doctor and hence follows instructions, thereby promoting his recovery. In all respects the panel system has proved itself more satisfactory than the project-doctor system."

The passage of time has confirmed Mr Overend's conclusions. After six months, Mr Brehon Somervell of the Works Progress Administration in New York City also reported that better treatment was being rendered under the panel system at lower cost. The workers are highly satisfied with the new arrangement. Medical abuses are at a minimum.

Part of the credit for these splendid results must undoubtedly go to the medical and administrative heads of the WPA for their intelligent cooperation with organized medicine. Both of the executives mentioned, as well as Dr Philip MacGuire, the Medical Director, have a genuine understanding of the factors involved in good medical service and an unusual ability to work in harness with unofficial bodies.

Above all, however, the results testify to the superiority of independent, competitive medical practice over a bureaucratic monopoly.

An Example for Us

Canada points the way to some badly needed reforms in the regulation of quasi-medical broadcasts. Under the new rules promulgated by the Canadian Broadcasting Corporation, the advertisement of foods, cosmetics, and patent medicines can be stripped of fraud and exaggeration if enforcement agencies show proper vigilance.

Among the new regulations, which are

Misuse of Public Money

In the November 13 issue of *The New York Medical Week* editorial attention was called to an Associated Press comment that the Home Loan Bank Board had contributed \$20,000 to support a co-operative medical clinic in Washington, to provide medical care for its employees and their families with no salary limit on the membership, and financed partly by government funds. *The New York Medical Week* challenged this misuse of public money.

In the New York *Herald-Tribune* of December 1, we find a news item from Washington quoting Senator Pat McCarran of Nevada. The article states that he called on officials of the Home Owners' Loan Corporation "to explain on what authority they have contributed \$40,000 of government funds to an experiment in collective medicine." We reproduce in full this news item from the *Herald-Tribune* Bureau in Washington in our "Current Comment" column. Here it suffices to state that Senator McCarran is reported to have said that he understood that the employees of several other departments were contemplating setting up similar systems to that of the HOLC. Senator McCarran warned, "Employees of these departments should realize that they place themselves in grave danger

when they exceed their authority and when they dispense government funds without legal authorization."

It is a sad commentary on these times, when the burden of taxation is almost unbearable on those who still have the will and the capacity to earn and save, that totally unauthorized expenditures of public moneys should go on without general public protest and criminal prosecution. There was a time not so long ago when no agencies of the government deliberately misused public money and diverted it from the purposes for which Congress appropriated it. In the sane state of the public mind then, such a procedure would have been unthinkable. In the "jog-trotting" of the present day, however, the old order seems passing and public morality and probity seems abating. Medicine never makes complaint against government money—local, state or Federal—expended for medical purposes where organized medicine sees real need, but where "socializers"—defeated in their efforts to receive through regular channels money appropriations for their schemes, are balked, then deliberately take money specifically allocated for other purposes and apply it to the development of pet schemes, then there is presented a situation that needs more than protest.

the exercise tolerance has been increased. A number who had been totally incapacitated by the disease, have resumed their former occupations or have become able to find gainful employment in other less strenuous fields.

Their patients have been seen by other physicians and these observations have been corroborated. The subjects themselves are well-satisfied with the results obtained. These are the outstanding clinical factors in the latest report of this work. Scientifically, several questions remain to be answered concerning the actual reasons for the beneficial effect achieved by the surgery. A clinical improvement is noted in most instances on the eighth or tenth postoperative day, and this cannot be ascribed to the creation of a new blood supply from the grafts implanted. The opening of intercoronary communications or the severance of nerve fibers during the removal of the epicardium may be the factors responsible for the relief of the patient's symptoms.

In any event, a contribution of such moment must be given serious consideration even at this early stage in its development. Based as it is upon sound experimental studies,³ its clinical application should be thoroughly investigated. The effectiveness of the operation can be determined only by further study. The time to operate, the selection of the patient as determined by age and stage of the coronary disease are questions which await an answer in the future.

Enuresis Treated with Ephedrine

The treatment of enuresis has always presented a problem to the physician since no one remedy has been found which will successfully ameliorate the condition in all sufferers. It occurs mostly in children and is not associated with any evident pathology of the urinary system.

It persists usually throughout school life and into the late teens and then spontaneously ceases in the early twenties.

In a study of thirty-eight consecutive unselected cases of enuresis, Brookfield¹ found that the type of enuresis alluded to above responds favorably to the administration of ephedrine internally. The method of treatment that he advocates is to give a one-half grain tablet of ephedrine alkaloid at bedtime and to increase this dose every third or fourth night. In some instances as much as five grains is taken by the patient. Where a favorable response to this form of therapy occurs, the enuresis at first becomes less frequent and then disappears entirely as the dose is increased.

He has found that many of his patients have tolerated amounts of ephedrine greatly in excess of those generally considered to be maximal. From this he feels that there exists a disturbance of the normal balance between the sympathetic and parasympathetic systems with a predominance of parasympathetic excitation. To overcome this hypertonicity, a comparatively large amount of ephedrine can be administered and utilized by the body before side reactions become evident.

Brookfield states that ephedrine therapy for enuresis should be employed in the majority of the younger patients. His report of cure in ten cases and marked improvement in fourteen others merits consideration by the practicing physician when confronted with a case of enuresis which does not respond to the forms of medication usually employed. Judicious use of the drug, and careful observation for the appearance of constitutional reactions are required. Since the enuresis is at most an annoyance and a source of unpleasantness to the patient which in time will cease of itself even though not treated, the use of ephedrine should not at present be a routine measure but should be tried only when other means have failed.

³ Beck, C. S. and Tichy, V. L. *Am Heart J*, 10: 849, 1935.

¹ Brookfield, R. W. *Lancet*, 2: 623, 1937.

remarkable for their simplicity and explicitness, several provisions stand out. No therapeutic recommendations may be made without the approval of the Department of National Health. Proprietary formulas must be submitted with the scripts advertising them. False or misleading statements are taboo.

Unfortunately, Canadians, like their American neighbors, are still exposed to the danger of misrepresentations emanating from this side of the border. So far broadcasting companies in the United States have shown little determination to put an end to exaggerated, misleading claims for foods, drugs, and cosmetics.

Broadcasts advertising laxatives violate sound physiological principles as well as good taste. The exaggerated claims made for cold "cures" and headache remedies encourage self-medication in many conditions requiring early medical care. Diathermy machines for lay use are advertised in misleading terms which minimize their danger and grossly overstate potential benefits.

In the face of these and many other evils, it is foolish to pretend that radio advertising is less venal or less in need of regulation in the United States than in Canada. There is plenty of foolish censorship to conform to provincial morality and sectional prejudices, but a consistent, intelligent policy to guarantee honesty in advertising is sadly lacking.

While some stations voluntarily maintain high standards and eschew any medical advertisements smelling of quackery, others sell time to any advertiser who can pay their rates without regard for the public good. Such stations can be curbed only by law, for as long as there is a safe profit in the dissemination of misstatements, they will lend their facilities to it.

The President's Address at the Fourth District Branch Meeting

Dr Charles Goodrich continues his campaign for preventive medicine and at

the meeting of the Fourth District Branch at Glens Falls he took up the question of prevention in reference to casual wound infections which may cause temporary or permanent disability, and from which a certain percentage of deaths occur.

To physicians he brings nothing new, but it would be well if the general public could have this address available for repeated rereadings. Preventive medicine would be much enhanced by public appreciation of what Dr Goodrich here presents. We carry the address in full in another column and we commend it to the attention of our readers (page 2101).

Surgery of Coronary Sclerosis

A considerable amount of favorable comment was aroused when in 1935 Beck¹ first proposed an operative technique whereby a new blood supply was furnished to the cardiac musculature. Since then, twenty-five patients have been operated upon and a sufficient time has elapsed to enable an early evaluation of the clinical results.

One of the significant points is the lowering of the mortality due to the surgery per se from fifty per cent in the earlier cases to 15.4 per cent in the last thirteen cases operated upon by Beck and his associates. In their most recent publication² they analyze the results obtained in thirteen patients who have been under observation for five months or longer postoperatively. In three, the results were striking—pain has completely disappeared, tolerance for exercise has been increased, and drug therapy has been discontinued. In nine, the results are "such as one might expect to obtain, considering the nature of the disease that is being treated." Pain, while present, is diminished considerably, medication is resorted to less frequently, and

"MANY ABORTIONS ARE UNDERTAKEN on the impulse of the moment, when an unexpected pregnancy clouds the immediate future. A friendly word of encouragement and warning, a discussion of the many risks, will often serve as a check until, after a few weeks of mental readjustment, the pregnancy is gladly accepted. Such a word must often come from the physician, but it is as valid from any other friend"—Dr Howard C Taylor, Jr asks 'What About Abortions?' in the November issue of *California and Western Medicine* from which we have quoted the above statement.

"WHEN WARS ARE DECLARED AND WAGED, the man with blood lust, the killer, stalks the page. There is no masquerade.

"During floods much of the hidden life buried in the mud of river bottoms is sloshed upon shore and bank, and as the waters recede queer forms of life, with dull eyes unused to daylight lie dying, dead, and decaying. There is no masquerade.

"And so with depressions—as they recede, the little man, the boy scouts in shoes too big who have been catapulted by chaotic events into prominence and prominent positions shout and spout and spend money earned by others who would rearrange the whole social order—they are on a grand unlimited jamboree, they await not the new order, they drag it in.

"With that borderline group of pink revolutionaries, the sweet male directors of funds and foundations, graduates of third rate cow colleges, east and west, and tenth rate minds pushed out of first rate universities—with this ilk we have a quarrel and we call the turn.

"Certain foundation and fund directors, and hangers-on, finding themselves in fair

position sustained and bolstered by sweet old lady-like types of both sexes—in that situation, they have position long denied them, they have opportunity to meddle.

"We don't believe in looking for trouble, but we would be less brave, if we kept silent, than a Foundation or a Fund Director who, making his living from largesse dispensed from money made by business, in slippery manner repays the hand that feeds him by seeking to socialize business"—Some sharp words by Dave Sugar in the *Detroit Medical News* which perhaps might be applied to an analagous situation in our own field.

A GREAT MANY FOLKS ARE FORGETTING that there are vitamins in strawberries and cream as well as in spinach and cod-liver oil. They are forgetting that it is pleasant to do most of the things that will make us strong and well. How long has it been since we were told that the banana was really not fit to eat? Why, there are millions of people living in the tropics who practically subsist upon the banana. Indeed it is the only fruit that will even fairly well serve as an exclusive article of diet. It is now known that bananas, provided they are neither green nor rotten, can be fed to even young babies. In fact, in a certain disease of children—celiac disease—the best medicine or diet that has been devised is an exclusive banana diet. The best health rule I know is the one that advises us to forget at least nine-tenths of the other health rules and just live naturally"—A happy reminder by Thurman B. Rice, M.D., Professor of Bacteriology and Public Health, Indiana University School of Medicine, to be found in full in *California and Western Medicine* of recent date.

MARY PUTNAM JACOBİ FELLOWSHIP

The Women's Medical Association of the City of New York offers the Mary Putnam Jacobı Fellowship, of \$1000 for one year, available for postgraduate work in the medical sciences.

The fellowship is open to any woman graduate of an approved Medical School. Each candidate must be endorsed by the head of the department in which her previous work has been done. The recipient of the fellowship must give full time to the study of her problem and this study should be made preferably abroad.

The recipient of the fellowship, if not resident in the United States, should make the study preferably in the United States.

Applications for 1938-39 should be filed with the chairman of the committee on or before April 1, 1938, and must be accompanied by statements as to health, educational qualifications, and proposed problem for investigation.

ANNIE S. DANIEL, M.D., Chairman of the Mary Putnam Jacobı Fellowship Committee, New York Infirmary, 321 E 15 St., New York City.

CURRENT COMMENT

FROM THE HERALD TRIBUNE BUREAU we learn that in Washington, under date of November 30 "Senator Pat McCarran, Democrat, of Nevada, today called on officials of the Home Owner's Loan Corporation 'to explain on what authority they have contributed \$40,000 of government funds to an experiment in collective medicine'."

"The reference was to the contribution by the HOLC and the Federal Home Loan Bank Board of \$20,000 for the operation of Group Health Association, Inc., giving medical care to employees of the HOLC and the FHLBB and their affiliated agencies. The GHA has been promised a further contribution of \$20,000 next year. A clinic has been in operation for several weeks.

"Senator McCarran in his statement said he had called on the HOLC officials for an explanation because 'there seems to be considerable doubt as to the legality of it.' The HOLC, he pointed out, was set up to lend money to private citizens on their homes or to guarantee loans already made.

"It was never contemplated by Congress,' the Nevada Senator wrote, 'that any money appropriated for the HOLC would be donated to any one or to any organization for any purpose. It certainly was not contemplated that any money would be donated for an experiment in collective state-subsidized medicine.

"The Comptroller General, whose duty it is to pass on all expenditures of government funds, should investigate this particular expenditure at once."

"Senator McCarran said that he understood the employees of several other departments were contemplating setting up a similar system to that of the HOLC.

"Employees of these departments should realize that they place themselves in grave danger when they exceed their authority and when they dispense government funds without legal authorization,' the letter continued. If Congress considers it wise to make experiments in socialized medicine, or in socialized anything else, Congress is quite competent to order such experiments. In the present case the officials of the HOLC were hired and are being paid by the government to run the affairs of that agency. They were not hired because of their social views or theories in collectivism."—*The New York Herald Tribune*, December 1

"AS NEVER BEFORE PHYSICIANS SHOULD be alert to economic changes and be informed of medical legislation and of the health programs and activities of lay organizations.

"Physicians busy with professional duties may readily get out of touch with fast moving changes in public opinion. The sympathetic public approved of plans to have taxes pay for the care of the tuberculous in clinics and institutions. Something is being done with public approval about crippled children. The public now demands something be done about syphilis. The public looks to the physician for leadership in these campaigns and if not found there will go elsewhere."—A warning from the *Pittsburgh Medical Bulletin* of recent date.

"IN AN ADDRESS TO A MEETING at Leeds,

Lord Horder said that inevitably the physician's work in the future will be more and more educational and less and less curative. More and more he will deal with physiology and psychology and less and less with pathology. He will spend his time keeping the fit fit rather than in trying to make the unfit fit. And we must make it worth his while to do this work. This reorientation of his education and his work is overdue, and it will remain overdue until reorientation takes place in the attitude of the health authorities toward him and his sphere of usefulness. And we must not think that his education is finished for all time when he becomes qualified. It is a duty we owe to every doctor to get him back now and again to the stimulating and informing atmosphere of the wards and the laboratories and, no less helpful, to the atmosphere created by his colleagues and teachers."—From a report in the *J.A.M.A.* of November 27 by its regular London correspondent.

"THE PRACTICE OF MEDICINE is the physician's business. Every successful man puts a certain amount of money back into his business and he keeps up with new advances or he is passed by his competitor. Every physician does have the time and money to spend in the improvement of himself in the practice of medicine. There is only one good excuse and that is inertia.

"—*The Sedgwick County (Kan.) Medical Bulletin* reminds the doctor of the necessity of "Holding One's Own."

"MANLY ABORTIONS ARE UNDERTAKEN on the impulse of the moment, when an unexpected pregnancy clouds the immediate future. A friendly word of encouragement and warning, a discussion of the many risks, will often serve as a check until, after a few weeks of mental readjustment, the pregnancy is gladly accepted. Such a word must often come from the physician, but it is as valid from any other friend"—Dr Howard C Taylor, Jr asks "What About Abortions?" in the November issue of *California and Western Medicine* from which we have quoted the above statement.

"WHEN WARS ARE DECLARED AND WAGED, the man with blood lust, the killer, stalks the page. There is no masquerade.

"During floods much of the hidden life buried in the mud of river bottoms is sloshed upon shore and bank, and as the waters recede queer forms of life, with dull eyes unused to daylight lie dying, dead, and decaying. There is no masquerade.

"And so with depressions—as they recede, the little man, the boy scouts in shoes too big who have been catapulted by chaotic events into prominence and prominent positions shout and spout and spend money earned by others who would rearrange the whole social order—they are on a grand unlimited jamboree, they await not the new order, they drag it in.

"With that borderline group of pink revolutionaries, the sweet male directors of funds and foundations, graduates of third rate cow colleges, east and west, and tenth rate minds pushed out of first rate universities—with this ilk we have a quarrel and we call the turn.

"Certain foundation and fund directors, and hangers-on, finding themselves in fair

position sustained and bolstered by sweet old lady-like types of both sexes—in that situation, they have position long denied them, they have opportunity to meddle.

"We don't believe in looking for trouble, but we would be less brave, if we kept silent, than a Foundation or a Fund Director who, making his living from largesse dispensed from money made by business, in slippery manner repays the hand that feeds him by seeking to socialize business"—Some sharp words by Dave Sugar in the *Detroit Medical News* which perhaps might be applied to an analagous situation in our own field.

A GREAT MANY FOLKS ARE FORGETTING that there are vitamins in strawberries and cream as well as in spinach and cod-liver oil. They are forgetting that it is pleasant to do most of the things that will make us strong and well.

How long has it been since we were told that the banana was really not fit to eat? Why, there are millions of people living in the tropics who practically subsist upon the banana. Indeed it is the only fruit that will even fairly well serve as an exclusive article of diet. It is now known that bananas, provided they are neither green nor rotten, can be fed to even young babies. In fact, in a certain disease of children—celiac disease—the best medicine or diet that has been devised is an exclusive banana diet.

The best health rule I know is the one that advises us to forget at least nine-tenths of the other health rules and just live naturally"—A happy reminder by Thurman B. Rice M.D., Professor of Bacteriology and Public Health, Indiana University School of Medicine, to be found in full in *California and Western Medicine* of recent date.

MARY PUTNAM JACOBI FELLOWSHIP

The Women's Medical Association of the City of New York offers the Mary Putnam Jacobi Fellowship, of \$1000 for one year, available for postgraduate work in the medical sciences.

The fellowship is open to any woman graduate of an approved Medical School. Each candidate must be endorsed by the head of the department in which her previous work has been done. The recipient of the fellowship must give full time to the study of her problem and this study should be made preferably abroad.

The recipient of the fellowship, if not resident in the United States, should make the study preferably in the United States.

Applications for 1938-39 should be filed with the chairman of the committee on or before April 1, 1938, and must be accompanied by statements as to health, educational qualifications, and proposed problem for investigation.

ANNIE S. DANIEL, M.D., Chairman of the Mary Putnam Jacobi Fellowship Committee, New York Infirmary, 321 E 15 St., New York City.

Audi Aleteram Partem

1251 Pacific St
Brooklyn

To the Editor

In the NEW YORK STATE JOURNAL OF MEDICINE, of November 1, 1937, and under the caption "Don't Despair of the Human Race," there appears a criticism of the views of Doctor Alexis Carrel, as expressed by him in a recent address. The writer ventures to disagree with the editorial, as follows

Far from looking upon man, only from a mountain peak, Doctor Carrel has also studied man in his most intimate parts and therefore from the closest point of view. He has observed and studied man in all of his states, in all of his actions. He has mixed with all grades of men as a fellow man, and has studied man, with the insight and guarded judgment, of a trained observer. He has studied man as an individual, as race, species, and as a universal. His study has been the very opposite of a lonely mountain view. The writer of "Don't Despair of the Human Race," sets up a straw man.

The editor says "we are trying to lift the whole people to higher levels." If one may be permitted to judge of intent, by results, this statement is incorrect. Those who are leading the people, are reducing the mass to lower levels, to the level of serfs, the levels of unthinking slaves, to the levels of centuries and centuries ago. That they have been able to do this to the degree that they have, is evidence of the correctness of Carrel's statements.

The editor further says "we are putting democracy to the test." This is absolutely incorrect. The fact is we have cast off democracy, and have returned to aristocracy—not an aristocracy by inheritance, but by political appointment from those who have unlawfully seized power, which they would not have been able to have done, had not man already degenerated.

The editor adduces the great number of pupils attending schools, as proof of advancement. Carrel has emphasized this same large attendance at schools, but Carrel points out the equally true but unfortunately concomitant fact, that moral

standards—"spirituality"—are no longer cultivated nor esteemed by the great mass. The editor makes the error of considering school buildings, and passing a great amount of variable material—pupils—through the school mill, as constituting or insuring culture. Carrel has emphasized the superficial mind of the mass today.

Carrel has emphasized the present production of increasing numbers of, otherwise healthy, morons, perverts, and criminals.

The editor ascribes to Dr. Carrel, a "philosophy of despair." On the contrary, Carrel incites to effort, to study, to the attainment of knowledge, to hope.

The editor says "The civilization of da Vinci and Lord Bacon is gone forever." Does he mean by this, that we will never again attain to the relative progress in manners, art, science, and statecraft, that obtained in the fifteenth, sixteenth, and seventeenth centuries? If such be so, then truly the editor's would be the philosophy of despair.

Yours truly,
W H STEERS, M D

A Help to the Mute

22 W 74 St,
New York City

To the Editor

It is my very sincere hope that the publication of this letter in some medical journal will help many mute invalids who, like myself, can no longer write or typewrite, but are still able to use the muscles which render winking possible. As for myself, being unable to tolerate light, I live in a darkened room with my eyes almost constantly shut. I am unable to open them voluntarily if they remain shut for a very few seconds. However, if some extraneous force opens them, I can very easily dictate my thoughts by certain winkings which I shall explain further on in my letter. Hoping to be of service to other mute individuals, I am dictating this compte rendu.

The fundamental basis of my system is the correspondence between the letters of the alphabet and the ordinal numbers one may attach to them. For each consecutive letter

I give the number representing its order in the alphabet. At first I used to indicate these numbers by means of the fingers, but the condition of my arms soon prevented me from continuing that method. Such numbers can most easily be evinced, however, by adding the numbers expressed by means of these winking.

Every simple winking of both eyes indicates 10, the left eye stands for 5, each winking of the right eye for 1. The letters I, N, R and S are somewhat lengthy to indicate by this general method. That is why I have particular signs for them.

I—the 9th letter in the alphabet is expressed by a contraction of the eyelids, or a prolonged tight winking of both eyes.

R—the 18th letter of the alphabet, is the same as two successive I's.

N—is a prolonged winking of the right eye.

S—is a prolonged winking of the left eye.

1—A	10—J	19—S
2—B	11—K	20—T
3—C	12—L	21—U
4—D	13—M	22—V
5—E	14—N	23—W
6—F	15—O	24—X
7—G	16—P	25—Y
8—H	17—Q	26—Z
9—I	18—R	

Kindly be good enough to read the letter I have written in 1933 to Professor C J Keyser, and which the editors thought it best to publish as a preface to my essay *Ecstasy* which I am sending under separate cover.

Very respectfully yours,

MAURICE SCLAKY

November 23, 1937

SERUM IN PNEUMONIA

That the physicians of the State may have concrete examples of different phases of anti-pneumococcus serum treatment of pneumococcus pneumonia, there will appear here case reports selected from the large number received by the State Department of Health on the use of anti-pneumococcus serum produced and distributed by it.

In order that physicians practicing in New York City or those using effective serum from other sources may also be represented, we hope that physicians who may have had particularly significant experiences with serum will submit short reports to the Pneumonia Editor, New York State Journal of Medicine, 33 W 42 Street, New York City—Editor

Case 8

Report from the records of the Lourdes Hospital, Binghamton

"A twenty-nine year old male adult with no history of previous illness had an onset of chilly sensations, followed by fever on March 3, 1937. On the following day he developed a cough productive of blood-tinged sputum. The patient was admitted to the Lourdes Hospital two days following onset of the disease (April 2) at which time he had signs of consolidation over the left lower lobe, confirmed by chest plate. The patient's temperature was 105°, pulse 120, and respiration 30. The sputum was typed immediately and a Type I pneumococcus was found.

"Serum therapy with Type I antipneumococcus serum was started and the patient received forty c c (50,000 units) intravenously on the day of admission. During the next five hours the temperature dropped to 102°. This remission was temporary, however, and by the morning of the third day of the disease, the temperature had regained its previous level where it was maintained in spite of two additional doses of 50,000 units each of Type I serum administered on that day.

"On the fourth day, because of lack of

response to serum therapy, the sputum was again typed and this time a Type VII pneumococcus was found. That evening two doses, each of 20,000 units of Type VII antipneumococcus serum, were administered. By noon of the following day, the temperature had dropped by crisis to 100.2° with dramatic improvement in the patient's condition. The temperature rapidly returned to normal where it subsequently remained.

"The patient's convalescence was uneventful, the chest being negative to physical examination on the eleventh day of the disease."

This case illustrates several important points. The patient was treated as a medical emergency, and sputum typing, skin testing, and serum administrations were carried out on the day of admission to the hospital. Also, serum was given in adequate dosage over a short period of time. During the first ten hours following the typing, the patient received 100,000 units of Type I serum and following a lack of response to this treatment, an additional 50,000 units was given five hours later. However, in spite of this the patient's condition remained unchanged.

When a patient with Type I pneumococci in his sputum does not respond to the early administration of as much as 150,000 units of Type I serum, it must be assumed for the purposes of treatment, that the patient has something more than uncomplicated Type I pneumococcus pneumonia. The common conditions that may be present in such a case are

- 1 Overwhelming infection with bacteremia
- 2 Error in original sputum typing
- 3 Localization of a focus, such as empyema, endocarditis, thrombophlebitis, meningitis
- 4 Mixed infection, either with another type of pneumococcus or with a hemolytic streptococcus, or other micro-organism.

Under such circumstances it is necessary that a very careful search for the complicating factors be made in order that the patient receive proper treatment. Such a search should include a careful physical examination, repeated blood cultures and a retyping and plate culture of the sputum.

In this case, the retyping of the sputum demonstrated another type of pneumococcus (Type VII) for which serum was also

available. It is impossible to say on the basis of the existing evidence in this instance whether the original typing was erroneous or whether the patient had an infection by the Type VII pneumococcus superimposed on a Type I infection, but the rarity of Type I pneumococcus as a contaminant would make one feel that it was probably the latter. However that may be, the therapeutic indications were clear. Type VII antipneumococcus serum was given and the patient had an immediate crisis. It should be emphasized that in the event that different types of pneumococci are found in definite specimens of sputum of the same patient, further sputum examinations should be made. These examinations should be correlated with previous findings and with blood culture data.

In this particular case, it might be argued that the crisis may have been a spontaneous one, not associated with the serum treatment. Whether or not this was so, it was obviously good therapeutic judgment to repeat the typing and to institute serum therapy for the second type as soon as it was accurately identified.

"GOODA MAN, GOODA MAN, GOD BLESSA"

The materializing influence of the machine age has at any rate not laid its cold hand on the profession of medicine. Countless instances like the one recorded below are occurring all the time, but this one happened to have an eloquent witness to tell us about it. The doctor was Warren Hildreth, of New York City, who died at his summer home at Southampton in October, and the narrator was an old friend, Rev. Jesse Halsey, of Cincinnati. The story appears in the *Southampton Press*. Said Dr. Halsey:

One summer night some six years ago Dr. Hildreth and I sat talking in his study. It was past midnight. The telephone rang. He answered. "Yes"—he would come.

I went with him, he driving his own car. It was away out beyond Jamaica that we went and to a very humble home—the wife of an Italian fruit-vendor needed his help. He the great physician with his demanding practice, went. I asked him, why? It was his job, he said. He had had this woman under his care while he was an interne years before. She needed him now again—desperately. And he was there. Fifth Avenue could wait.

At length he called an ambulance and brought

his patient back to Sloane and back to life ere morning. At breakfast time he came in tired—but happy. The fight was won.

I had driven his car back home, thinking many thoughts, that early morning. But before I left the little house in the suburb I had heard the little grandmother say a dozen times, "Gooda man, gooda man, God blessa." And the young doctor who was there doing his best, before the great doctor arrived, came out to the car and said, "You're lucky, sir, to be his friend. You should have seen him, he never shamed me before my patients. You'd have thought he was my assistant. He's a great man, sir!"

Yes, "God" and "Great" and great because good. Humble, strong, gentle, manly and with highly developed technical skill—all at the disposal of those in need! He gave himself.

Now he has taken with him, as is meet, his wisdom and his skill. But he has left us a goodly heritage and we rejoice in his tireless industry, in his great achievement and in the high place he holds in the respect and affection of many, many men and women and children—little and big.

We sorrow with his family, yet we rejoice in the love and pride which they feel in him. We thank God for the personal qualities that endeared him to us all, his belief in the pure, the true, the good, his patience, his courage, his willingness to serve.

Doctor "Well, madam, what is your ailment?"

Old Lady "Pains in my arms, doctor

I can hardly lift them over my head, and it's the same with my legs."—*Four Mich. State Med. Soc.*

THE WOMAN'S AUXILIARY

To the Medical Society of the State of New York

New Years bring new problems and we wonder what the coming years have in store. Let us be prepared!

There was a time when organized medicine was on an undisturbed plane, when doctors were placed on pedestals and looked up to as gifts from God to suffering humanity. But today there are many forces working against this noble profession, either through ignorance or for political reasons, endangering the welfare of the public as well as the profession.

Have the laity of this generation forgotten the great plagues which once existed: yellow fever, smallpox, malaria and diphtheria? Have they forgotten the great men who gave untiringly of their time, knowledge, experience, and in fact offered their lives to wipe out those great scourges?

Do they realize that the standard of men accepted into this profession is ever being raised, that qualifications of medical students are higher, that the selection is more careful, that the cost of medical training is increasing, that medicine unceasingly marches on?

Do not tie the hands of these men by permitting the government to control their practice. Let that high standard of ethics, the Hippocratic Oath, continue to govern this great body as it has in the past. Give them the right to crusade against tuberculosis, cancer, pneumonia, syphilis, and all other diseases free from government antagonism now and forever.

The Legislature will convene in January and I would suggest that each County Auxiliary Chairman of Program plan to devote one meeting to the study of bills pertaining to medical legislation which will come before that body, that all members become properly informed on the views of organized medicine on such bills, and that those views be brought convincingly before the public. However, each County Auxiliary must at all times proceed under the guidance of its Advisory Council.

I have recently returned from the A.M.A. Auxiliary Executive Board meeting held in Chicago and feel more than ever the great privilege it is to be a member of such an organization, such high type women, so sincere in their efforts. And I

would like here to mention a few abstracts from the reports of State Auxiliary Presidents given at that meeting:

Alabama reported a scholarship fund for worthy medical students.

Colorado also reported a benevolent fund.

In Florida each County Auxiliary sets aside a fund sufficient to take care of delegates' expenses. The study of the Handbook is also stressed.

The Oregon State Auxiliary sent 500 letters to Parent Teachers Associations throughout the State, suggesting approved material for programs. 125 requests were received to date. 140 speakers from the Medical Societies are available to clubs.

South Dakota, over twenty years old, regretted to report that an osteopath was put on the State Board before the doctors knew about it.

The State of Utah reported one hundred per cent organization and a copy of *Hygeia* in every school in the state.

The Texas Auxiliary is establishing a State Library, collecting old medical books and medical pictures. Texas also reported that the sum of \$50,000 was willed by one doctor to aid this project.

Wisconsin has Hygeia Day. Every County Auxiliary is asked to do something on that day to raise funds to place *Hygeia* in the schools. In one week 101,000 people visited this Auxiliary's Hall of Health Exhibit.

Pennsylvania reported 2640 members and the sum of \$4570 added to its benevolent fund this year. The fund is being used to assist thirty-one needy doctor's widows. This State Auxiliary also gave \$250 to Mrs. Keck, National President, to use at her discretion in carrying on her work. Part of this sum she will use to have the national archives bound.

Every State reported increases in membership.

And while just in the second year of our existence, New York reports progress in every way.

Jefferson County was organized on November 11. A dinner preceded the meeting. Thirty-five women were present.

including Mrs John J Buettner, State Chairman of Organization and myself. We wish to extend to Mrs Harlow Farmer, first president, and her officers, chairmen and members, a hearty welcome, and we wish to congratulate Mrs Walter Fox Smith and her excellent committee for their stimulus and aid in organizing.

Best wishes also go forth to Mrs S P Jones of Mattituck who was elected president of the Woman's Auxiliary to the Suffolk County Medical Society at the annual meeting and luncheon held on November 17 at the Riverside Inn, Smithtown.

Mrs Luther H Kice, State Chairman of Legislation, addressed the group. Being a doctor's wife, doctor's daughter, and

doctor's mother has given Mrs Kice a wealth of experience in medical work.

I cannot urge too greatly the value of the National News Letter to County Presidents, and suggest that, if she has not already done so, she should send in her subscription of our State Chairman of Press and Publicity, Mrs Milton B Bergmann, 959 Bushwick Parkway, Brooklyn. Outside of the National Convention, this is your strongest tie with the A M A Auxiliary. To know the activities of your sister auxiliaries is an untold help and inspiration.

Let us all plan to attend the State Convention to be held in New York City May 9-12.

MRS FRANCIS R IRVING
President

1938 A M A MEETING—SAN FRANCISCO

When San Francisco was selected as the host city for the 1938 Annual Session of The American Medical Association, the profession of this Golden Gate Metropolis promptly initiated plans for the comfort, pleasure and entertainment of all who come to that national meeting. A local executive committee on arrangements composed of five members with Dr Howard Morrow as General Chairman and Dr Frederick C Warnshuis as General Secretary, and eighteen sub-committees have been busy since July in developing plans and local arrangement details. Their objectives are the biggest, best, and most memorable annual session in the history of the American Medical Association.

Atlantic City, Kansas City, Cleveland, Detroit, with their known facilities and attractions have been host cities in recent years, and have justified their selection as meeting places. However, and without disparagement, none of them possess the background, the setting, the resources, the history and romance, or the facilities that are

found in San Francisco and in the great state of California—the Golden Bear Empire of the Pacific Coast. To reveal these, to extend California's and San Francisco's noted hospitality, and to cause those who plan to attend the 1938 session to experience ten days of profit and pleasure midst the environs of the annual meeting city, is the goal toward which the local profession is pointing.

The Local Committee on Arrangements cordially invites the profession of the country to be San Francisco's guests this coming June. Decide now to attend the 1938 American Medical Association Meeting and plan accordingly. During the coming months an insight to some of the feature functions will be disclosed, but the final details and program of events will not be revealed until you arrive. You will long regret it if you fail to attend the coming national meeting. Talk it over tonight with the good wife and your professional associates, and join the party of your state members that is coming to San Francisco.

'FEW ARE CONVERTED AFTER THE FIRST 20 MINUTES'

That is as true of medical papers as it is of sermons, remarks President Joseph R Wiseman of the Onondaga Medical Society, in its *Bulletin*. And he gives a few more helpful hints for speakers at medical meetings, thus:

You may better adhere to your allotted time if you put your ideas on paper and then stick to what you have written without too many extra interpolations. Unless you have acquired the art, and it can be acquired, of expressing

yourself clearly and easily without the aid of the written page, your delivery will prove to be much more effective if read from a prepared paper.

The interest of the audience varies inversely with the amount of attention which the speaker pays to his manner of reading or speaking. Papers which are read in a monotone, with no change in pitch, and with no attempt to emphasize the important words or phrases, do not go over very well. A pause is one of the most effective methods of emphasis and often creates as good an impression as loudly spoken words.

Public Health News

Public Health Notes

J ROSSLYN EARP, L R C P, D r P H
New York State Department of Health

Attendance at County Meetings

In his address to the American Public Health Association Dr Charles H Goodrich stressed the importance of health officers attending the meetings of their county medical societies. A perusal of the reports of district state health officers encourages belief that at least some of them really do attend. When Dr Julius Hess spoke recently to the Albany County Society, the district health officer not only attended himself with his medical staff but he also telephoned to the health officers of the three large cities in his district and they too were duly present. Schenectady sent health officer, deputy health officer, and school medical inspector.

In another district Dr Hess's address to the Onondaga County Medical Society was made the occasion for launching a program of nursing care for all premature infants. Physicians cooperate by reporting the name of every infant who weighs less than 5½ pounds at birth. The city health department and the county public health nursing service contribute the nursing care

Periodic Medical Examinations

In the same speech in which he urged health officers to attend the medical society meetings, Dr Goodrich warmly advocated the periodic medical examination as a method of preventive medicine which deserves the interest of every practitioner. Here is a subject worthy of discussion at the county meetings.

The periodic examination has not been

without its critics. Some have complained that it makes hypochondriacs. If so, the blame must be placed not so much on the method as on the manner of its accomplishment. A discussion of this point might draw attention to a need for more psychology in the medical curriculum.

Others who wish to discredit the examination relate cases of patients who have died from heart disease within a year of taking the routine tests. Obviously this might happen after a perfectly adequate examination. The blame in this case lies with us writers who try to educate the public. We ought not to advocate examinations as a sort of insurance against every bodily ill. It is enough that some diseases may sometimes be caught in an early curable stage. And as our knowledge and technic advance more ills will be disclosed at even earlier stages.

A few years ago we were teaching the public the symptoms of "early" tuberculosis. Now we teach that "early" tuberculosis has no characteristic symptoms. It all depends on what we call "early" and what we mean by "symptoms." And that brings up the question of whether any periodic health examination is complete without a chest x-ray. And there are cognate questions such as how much time should the examination take? What laboratory tests should be made routinely? Where should reference to specialists be required?

There seem to me to be several aspects of this subject which would be worth talking over whenever health officers and practicing physicians meet together.

Thirty women physicians in Russia have completed their studies in parachute flying at the Moscow regional parachute school for the purpose of taking first-aid to patients in places where airplanes cannot land.

For the first time in many years a decline in the number of newly matriculated students of medicine at Vienna University is plainly observable, says a report in the *A. A. Journal*. It is declared to be "an

obvious consequence of the bad prospect presented by the medical profession in Austria. Private practice is being rapidly and steadily ruined by socialized medicine."

Arkansas reports an invasion of fake instrument salesmen, who call on doctors with meager stocks of samples, take orders at bargain prices, ask a deposit, and are never seen again. The physician finds too late that the company is mythical.

Medical News

Albany County

THE ANNUAL MEETING OF THE Medical Society of the County of Albany was held at the Albany College of Pharmacy on Dec 1. Officers for the ensuing year were elected.

ON NOVEMBER 22 THE Albany County Bar Association were hosts to the County Medical Society. Max D Steuer, of New York City, spoke on "Medicine and the Law."

DR ARTHUR SAUTTER died on Nov 11. He was sixty-eight.

Bronx County

A TESTIMONIAL DINNER was given Drs Thomas H Curtin and Clarence H Smith by the medical staff of Morrisania Hospital at the Biltmore Hotel on Nov 27, on their appointments as consulting ophthalmologist and consulting otolaryngologist, respectively. Dr Curtin was a member of the original advisory committee which planned the organization of the Medical Staff and construction of Morrisania City Hospital. Dr Smith is one of the founders of Union Hospital of the Bronx and since 1910 has been its Attending Otolaryngologist. In 1929 he became affiliated with Morrisania Hospital as its first visiting Otolaryngologist. Since retirement from active service he has become consulting Otolaryngologist at the hospital.

Broome County

DR WORDEN KANE PRESENTED a paper on "Neuro-Surgical Problems" at the meeting of the Broome County Medical Society in Binghamton on Nov 9. Dr Charles D Squires and Dr Louis J Bragman led the discussion.

Cayuga County

THE MEDICAL SOCIETY OF THE County of Cayuga and the Cayuga County Bar Association met for their second annual joint meeting November 18th.

Mr Miller, Instructor at the Syracuse College of Law, discussed the application and effect of Section 352 of the Civil Practice Act, which provides that physicians

and nurses shall not disclose information acquired in attending a patient.

Erie County

THE FIVE-YEAR FIGHT of the Medical Society of the County of Erie to obtain compensation for Buffalo physicians for treatment of patients on the welfare rolls has entered a new phase following approval of the so-called "O'Gorman plan" at the society's November meeting by a vote of 271 to 63.

As a result of approval of the plan, which calls for an allotment of funds to the society by the city on the basis of so much a month for each family or each member of a family on the relief roster, the society's committee on economics, headed by Dr Joseph C O'Gorman, sponsor of the plan, will approach city officials with the view of obtaining funds to carry out the proposal.

Under the plan, its proponents say, the potential rate of pay for indigent cases may range from twenty-two to thirty-five cents an individual a month. Some of the detailed provisions of the O'Gorman plan are:

- 1 The Medical society proposes to furnish medical care in the home to the indigents of Buffalo based on subsequently agreed monthly flat rate per family or per individual on welfare.

- 2 The administration of the care will be under the sole direction of the Medical society and will embrace free choice of physicians and assignment by the society where no choice is made.

- 3 All details pertaining to the administration of the plan will be directed from the office of the Medical society in Hotel Statler.

- 4 Any physician who is licensed to practice in the state of New York and who is registered with the county clerk's office of Erie county may register with the Medical society to serve under this plan.

- 5 The agreed monthly budget, less cost of administration, will be allocated by the society to the physicians on a basis of services rendered.

- 6 Drugs, medicines and supplies prescribed will be furnished by a separate agreement approved and financed by the Buffalo Board of Public Welfare.

- 7 This plan applies only to medical care in the home and is not intended to replace existing hospital or clinic facilities.

Dr O'Gorman explained that it is not the plan to have the medical society actually handle city funds, but for it to determine the amount due a physician and present his bill to the Welfare department for payment.

from the funds budgeted for the medical care of the indigent.

Most of the sixty-three negative votes were cast by members of the society from Erie county outside of Buffalo, proponents of the plan declared.

These members they explained fear that adoption of the "O Gorman plan" in Buffalo may result in a reduction in the fees now being paid physicians of the county outside of Buffalo for treating indigent patients.

The present compensation outside of Buffalo is \$1 an office call and \$2 a home call, forty per cent of which is returned to the county by the state.

Candidates were nominated at the session for the annual election Dec. 20. Dr. Harry C. Guess, first vice president was nominated to succeed Dr. John T. Donovan in the presidency. Dr. Carlton E. Wertz now second vice president, was nominated for first vice president.

Nominated for second vice-president were: Dr. Stephen A. Graczyk, Dr. Herbert E. Wells and Dr. Harvey P. Hoffman.

Dr. Louise W. Beamis, secretary, and Dr. Caryl A. Koch, treasurer, were nominated to succeed themselves.

SOCIALIZED AND SUBSIDIZED medicine were discussed by Dr. Irvin Abell of Louisville Ky., president-elect of the American Medical Association, and Dr. Morris Fishbein of Chicago, editor of the *Journal of the American Medical Association*, before the Buffalo Academy of Medicine on Nov. 17.

Dr. Abell spoke at a clinical session in the afternoon and Dr. Fishbein was the speaker at dinner in the evening, both in Hotel Statler.

Dr. Abell, who is also clinical professor of surgery in the University of Louisville School of Medicine, considered the "Responsibility of the Profession." Dr. Fishbein's subject was "Social Security and the Physician."

Three other medical authorities spoke at the afternoon clinical session.

Dr. Rudolf Schindler, associate professor of medicine in the University of Chicago school of medicine, "Diagnosis of Lesions of the Stomach by Gastroscopy."

Dr. Robert Louis Levi, professor of clinical medicine in the Columbia University College of Physicians and Surgeons, "Drugs in the Treatment of Diseases of the Heart."

Dr. Richard Bartley Cattell of the Lahey clinic, Boston, Mass., "Diagnosis and Management of Surgical Diseases of the Colon and Rectum."

CAROLINE LICHTENBERG, thought to

be the oldest woman physician in Western New York, died on Nov. 14 in Buffalo, after an illness of four months. She was seventy-two. For almost forty years Dr. Lichtenberg practiced medicine in the house in which she was born in Buffalo. She retired two years ago.

Franklin County

Dr. SIDNEY FRANCIS BLANCHET, a practicing physician at Saranac Lake for more than twenty-five years, died on Nov. 12 at the Columbia Medical center in New York City, where he had been a patient since Easter.

Greene County

Dr. ALTON B. DALEY was elected president of the Greene County Medical Society at the annual meeting at Walters Hotel, Cairo.

Other officers were named as follows:

Dr. George L. Branch, vice president, Dr. William M. Rapp, secretary, Dr. Mahlon H. Atkinson, treasurer, Dr. Percy G. Waller, chairman of the Legislative committee, Dr. William A. Petry, chairman of the Public Relations committee, Dr. Kenneth Bott, delegate to the State Society, Dr. Edwin G. Mulbury, alternate to the State Society.

Dr. Henry Tebbutt was guest speaker.

Herkimer County

ANOTHER STEP in the formation of a medical staff at Herkimer Memorial hospital was taken by the Herkimer Academy of Medicine at a meeting at the home of Dr. F. M. Neuendorf, on Nov. 16.

The physicians passed a resolution recommending that the present officers of the academy be retained as officers of the new staff.

Officers of the academy are: President, Dr. James W. Graves, vice president, Dr. John E. Canfield, secretary, Dr. Howard C. Murra, treasurer, Dr. F. H. Moore.

Kings County

THE PROGRAM AT THE November 16 meeting of the Medical Society of the County of Kings included:

(a) Address "Vitamin Requirement and the Clinic," George P. Cowdell, Ph.D., New Haven, Conn. (b) Address "Diagnosis of Diseases of the Liver," Richard Bauer, M.D., Vienna, Austria. (c) Presentation of Portrait of Dr. Glenworth R.

Medical News

Albany County

THE ANNUAL MEETING OF THE Medical Society of the County of Albany was held at the Albany College of Pharmacy on Dec 1. Officers for the ensuing year were elected.

ON NOVEMBER 22 THE Albany County Bar Association were hosts to the County Medical Society. Max D Steuer, of New York City, spoke on "Medicine and the Law."

DR ARTHUR SAUTTER died on Nov 11. He was sixty-eight.

Bronx County

A TESTIMONIAL DINNER was given Drs Thomas H Curtin and Clarence H Smith by the medical staff of Morrisania Hospital at the Biltmore Hotel on Nov 27, on their appointments as consulting ophthalmologist and consulting otolaryngologist, respectively. Dr Curtin was a member of the original advisory committee which planned the organization of the Medical Staff and construction of Morrisania City Hospital. Dr Smith is one of the founders of Union Hospital of the Bronx and since 1910 has been its Attending Otolaryngologist. In 1929 he became affiliated with Morrisania Hospital as its first visiting Otolaryngologist. Since retirement from active service he has become consulting Otolaryngologist at the hospital.

Broome County

DR WORDEN KANE PRESENTED a paper on "Neuro-Surgical Problems" at the meeting of the Broome County Medical Society in Hampton on Nov 9. Dr Charles D Squires and Dr Louis J Bragman led the discussion.

Cayuga County

THE MEDICAL SOCIETY OF THE County of Cayuga and the Cayuga County Bar Association met for their second annual joint meeting November 18th.

Mr Miller, Instructor at the Syracuse College of Law, discussed the application and effect of Section 352 of the Civil Practice Act, which provides that physicians

and nurses shall not disclose information acquired in attending a patient.

Erie County

THE FIVE-YEAR FIGHT of the Medical Society of the County of Erie to obtain compensation for Buffalo physicians for treatment of patients on the welfare rolls has entered a new phase following approval of the so-called "O'Gorman plan" at the society's November meeting by a vote of 271 to 63.

As a result of approval of the plan, which calls for an allotment of funds to the society by the city on the basis of so much a month for each family or each member of a family on the relief roster, the society's committee on economics, headed by Dr Joseph C O'Gorman, sponsor of the plan, will approach city officials with the view of obtaining funds to carry out the proposal.

Under the plan, its proponents say, the potential rate of pay for indigent cases may range from twenty-two to thirty-five cents an individual a month. Some of the detailed provisions of the O'Gorman plan are:

1 The Medical society proposes to furnish medical care in the home to the indigents of Buffalo based on subsequently agreed monthly flat rate per family or per individual on welfare.

2 The administration of the care will be under the sole direction of the Medical society and will embrace free choice of physicians and assignment by the society where no choice is made.

3 All details pertaining to the administration of the plan will be directed from the office of the Medical society in Hotel Statler.

4 Any physician who is licensed to practice in the state of New York and who is registered with the county clerk's office of Erie county may register with the Medical society to serve under this plan.

5 The agreed monthly budget, less cost of administration, will be allocated by the society to the physicians on a basis of services rendered.

6 Drugs, medicines and supplies prescribed will be furnished by a separate agreement approved and financed by the Buffalo Board of Public Welfare.

7 This plan applies only to medical care in the home and is not intended to replace existing hospital or clinic facilities.

Dr O'Gorman explained that it is not the plan to have the medical society actually handle city funds, but for it to determine the amount due a physician and present his bill to the Welfare department for payment.

A report of the election in the New York *Post* says

The first organized attempt by rank-and-filers within the New York County Medical Society to wrest the four important committee chairmanships from the regulars went down to defeat at the annual election meeting at the Academy of Medicine last night.

The Joint Committee of Physicians Organizations, the rank-and-file group, was far from discouraged by the 2 to 1 defeat, however.

The rank-and-filers saw in their vote—out of a total of about 750 cast—a mandate to continue their program.

They are fighting for pay for part-time doctors working in city clinics and hospitals, pay for internes, prevailing rate of fees from the Emergency Relief Bureau and affirmation of the policy that "the health of the people is the direct concern of government."

The defeated candidates included Drs. Harry S. Mackler, Israel E. Kirsh, Louis Finger and Lillian DeMuth, who sought the chairmanships of the committees on legislation, civic policy, economics and membership.

There was no opposition to the regular slate of executive officers.

DR. HARRISON S. MARTLAND, Professor of Forensic Medicine, New York University College of Medicine, will speak at the New York Academy of Medicine at 8 15 P.M., Dec. 23, on "Dr. Watson and Mr. Sherlock Holmes."

DR. EUGENE M. LANDIS, Assistant Professor of Medicine, University of Pennsylvania, will speak at the New York Academy of Medicine at 4 30 P.M. Dec. 17, on "Recent Advances in the Diagnosis and Treatment of Peripheral Vascular Diseases."

THE 1938 WILLIAM H. NICHOLS Medal of the New York section of the American Chemical Society has been awarded to Dr. Phoebus A. T. Levene of the Rockefeller Institute for Medical Research.

DR. GEORGE B. WALLACE, pharmacologist and senior member of the faculty of the New York University College of Medicine,

was honored by the presentation to the college on Nov. 15 of an oil portrait of himself at exercises commemorating his thirty-six years of teaching in the institution. More than 100 persons attended the ceremony in the Student Lounge of the College of Medicine.

Niagara County

DR. RUSSELL T. CECIL, professor of medicine at Cornell University, spoke on "Recent Progress in the Arthritis Problem" at a meeting of the Medical Society of the County of Niagara on Nov. 9. Dr. Nelson G. Russell and Dr. Maxwell Lockie led the discussion. A subscription dinner was given at the Hotel Niagara preceding the meeting.

THE ANNUAL MEETING was held at the Niagara Hotel, on Dec. 14. Drs. David J. Kaliski and Frederic Elliott of the Workmen's Compensation Committee, were the guest speakers—*Reported by Forrest W. Barry, M.D., Sec.*

Onondaga County

DR. DAVID F. GILLETTE was nominated for the presidency of the Syracuse Academy of Medicine at the November meeting. Speakers and leaders of discussions which followed were Dr. Wardner Ayer, Dr. H. Walden Retan, Dr. Paul Lowry, Dr. E. J. Goldman and Dr. Leo E. Gibson.

Other nominees were Vice-president, Dr. P. K. Menzies and Dr. Brooks W. McCuen, secretary, Dr. Floyd Parker and Dr. George S. Reed, treasurer, Dr. Ellery G. Allen and Dr. Clifford E. McElwain, council, Dr. Brewster Doust, Dr. Mortimer G. Brown and Dr. Carl E. Muench, trustees (three to be elected), Dr. F. C. Ruhson, Dr. D. S. Childs, Dr. Gerald C. Cooney and Dr. Leo E. Gibson.

Orange County

DR. FRANK D. MYERS was elected president of the Orange County Health Association at the annual meeting in the parish house of the Goshen Presbyterian Church on Nov. 10. He succeeds the Rev. Forrest P. Hunter, president for the past five years.

DR. ROBERT E. PLUNKETT, superintendent of state tuberculosis hospitals, spoke on the public's responsibilities in tuberculosis control. He was introduced by Dr. D. R. Gordon, superintendent of Odell Sanatorium.

Queens County

DR. JOHN L. KANTOR, of Montefiore Hospital, spoke at the Queens County So-

Butler Gift of Mrs Glentworth R. Butler Presentation speech by Dr Robert L Dickinson Unveiling by Dr Butler's grandson, Glentworth Butler Hewitt.

DEVELOPMENTS IN TREATMENT for the hard of hearing were discussed at a meeting held under the auspices of the section of laryngology, rhinology and otology of the Medical Society of Kings County at the society's headquarters, on Nov 10 About 150 physicians attended the meeting

Addresses were made by Dr John W Durkee, senior surgeon at the Brooklyn Eye and Ear Hospital, whose subject was "The Hard of Hearing Patient and His Physician," State Senator Jacob H Livingston, who told of "Current Events in the Work for the Hard of Hearing," and Joseph J Endres, chief of the Bureau for Physically Handicapped Children of the State Department of Education Senator Livingston is chairman of a State Legislative commission which is investigating facilities for treatment of the deaf and the hard of hearing, and is chairman of the Senate Committee on Public Relief and Welfare In his address he told of the work of the commission which he heads

Estelle E Samuelson, secretary of the New York League for the Hard of Hearing, answered questions pertaining to the work of her organization

A MEETING OF THE Medical Society of Bay Ridge was held at the Shore Road Academy on Nov 9 Dr Pedro Platou presided The subject of the evening was a paper on "The Endocrine of the Menopause" by Raphael Kurzrok, M D The discussion was opened by Charles Howard Bernberg, M D, and George Hamilton Davis, M D, F A C S, and then continued by members of the society About sixty physicians were present

A BROOKLYN UNIT of the League for the Advancement of Socialized Medicine and Dentistry was organized by 75 physicians and dentists, who met at 62 Hanson Place on Nov 23

Addresses favoring socialization of the professions were made by Dr Jones Selverstone, a dentist, and Dr Joseph Slavitz, a physician Dr Herman Ausubel, former president of the Kings County Dental Society, was chairman

THE FOLLOWING MEETINGS of local Medical Societies were scheduled for early December

Dec 6—Monday East New York Temple Auditorium, 251 Rochester Ave, 9 00 pm 1 "Bleeding in Pregnancy," Harry

Aranow, M D, Manhattan 2 "Sterility Its Causes, Investigation and Treatment" (a color motion picture presentation), S L Siegler, M D, Brooklyn

Dec 9—Thursday South Brooklyn Y M C A, 9th St and 6th Ave, 9 00 pm "The Relief of Symptoms in Pulmonary Disease," Burgess Gordon, M D, Philadelphia "Back Injuries in Industrial Cases," Leopold Brahdy, M D, Manhattan

Dec 13—Monday Williamsburg Medical Leon Louria Auditorium, Jewish Hospital, St Marks and Classon Aves, 9 00 pm "The Menopause and Its Modern Treatment," Samuel H Geist, M D, Manhattan

Nassau County

A CONFERENCE WAS HELD on Nov 19 at the Hempstead town hall because of a sudden rise in mad-dog bites and cases of rabies in pets in Nassau county, particularly in the towns of North Hempstead and Oyster Bay Dr Dickinson presided at the session, which was attended by Dr William H Runcie, health officer of the town of Hempstead, Dr Charles A Steurer, health officer of the town of North Hempstead, Dr Raymond E Lease, health officer of the town of Oyster Bay and health officers from eighteen villages

The report of two cases of rabies in North Hempstead and one in Oyster Bay was read at the meeting Although no rabies cases have been reported in the town of Hempstead it was agreed to include the entire county in the certification because of the danger of infected animals traveling about the county

Dr Dickinson will submit a recommendation to the state health commissioner urging that the state law pertaining to rabies epidemics be applied to Nassau county

When the existence of rabies is officially recognized by the state authorities all dogs must be muzzled or leashed while on the public highways or they will be subject to immediate seizure

Dog catchers are authorized under the state law to destroy immediately all dogs picked up if they show any evidence of rabies Municipalities where the dogs are picked up must pay the dog catcher \$4 for each animal destroyed Dogs not destroyed may be redeemed by their owners for \$2

New York County

THE ANNUAL MEETING OF THE Medical Society of the County of New York was held at the Academy of Medicine on November 22, and these officers were elected

President-elect, Howard Fox, M D, first vice-president, Walter P Anderton, M D,

Hospital News

Confusion Over Secrecy of Hospital Records

AN ENTERTAINING FEATURE OF the convention of the Hospital Association of New York State last spring was a clever skit, or playlet, in three scenes, picturing the attempt of a shyster lawyer to get his hands on the hospital record of a patient whose case was to come up in court. He was foiled by the strategy of the record librarian, record room clerk, and hospital's attorney, and their legal maneuvers in the play were meant to show the assembled hospital representatives how to handle such tricksters. The legal crook was played by Mr. Leighton M. Arrow-smith, Superintendent of St. John's Hospital of Brooklyn, who wrote the piece. At one point in the play the record librarian remarked to the record clerk:

"You've got *lots* to learn. The Hospital Record Room is the natural prey of all kinds of crooks. We *hold secrets* that would be worth a mint of money in the wrong hands. Many a blackmail suit has started from a patient's history. I'd hate to think that some slicker put one over on me. But, believe me, I'm on my guard every minute. You've just got to be tough in this job, Alice, and I mean real tough."

Legal Atmosphere Is Foggy

And it isn't as if the hospital can always be sure of the support of the law, either, it seems, for the legal situation on this point is decidedly foggy. Before the presentation of the skit by the Arrowsmith players a valuable paper on the "Legal Status of Hospital Patients' Records" was read by Dr. A. R. Bowles, Assistant Director of the Grasslands Hospital at Valhalla. He hoped, he said, that his remarks would "add stimulus to the current movement to induce all hospitals in the state to adopt and to enforce uniform regulations concerning the usages of their medical records."

He began by asking "What is the legal status of hospital medical records in this state?" and replied "Frankly, I don't know, and I am not sure that anyone knows." He proceeded

"First, let me explain the basis of the bold statement I have just made

"During the past two years, I've had a lot of fun arguing with lawyers and with representatives of insurance companies who have come to the hospital to demand access to the records of particular patients. Those of you who have had to deal with these pestiferous fellows know that there seems to be no end to the contentions they can think up, nor any bottom to their bag of cagey tricks. Of necessity, I have had to fall back time and again upon the hospital's legal counsel and have spent quite a bit of time delving into law books with them. Thus far, we have been unable to find a clear-cut, uncontrovertible definition of the status of hospital medical records, as confidential documents, either in the statutory laws or in the decisions of the high courts of this state. This seems almost incredible. Yet I think we have gone into at least the most obvious reference resources

"Here is another important point. During the last two years we have had disputes with certain of the judges in County Courts and in the Supreme Court, in our area. These judges are all learned and highly respected men, yet they are, apparently, not in agreement as to the status of our hospital medical charts. Some of them treat them as confidential documents while others treat them very much as they would books of account, statistics, or what have you. For example, some time ago, we were served with a court order to display the record of an ex-patient to the lawyers of her husband, in preparation for annulment proceedings. Needless to say, we put up strong resistance and offered to make a test case of it. The lawyers for the husband backed down and agreed to have the order vacated. Then again, our records, taken to court in answer to subpoenae duces tecum, have been ordered by some of the judges to be shown to the lawyers before the patient had testified as to his illness or injuries, whereas, other judges do not permit such a practice.

"Thus, we have confusion among lawyers and apparently also among some of the judiciary, regarding the status of medical charts. I need hardly mention that there is plenty of confusion among the hospitals."

ciety Building on Nov 19 on "Disorders of the Colon"

Rensselaer County

INTERESTING PAPERS WERE READ at the meeting of the Rensselaer County Medical Society on Nov 9, one on "Bell's Palsy" by Dr James C Donnelly, and the other on "Diagnosis and Management of Pneumonia" by Dr Edwin A Locke former physician-in-chief of the Boston, Mass, City Hospital

Officers were nominated, to be voted upon at the December meeting

DR M J KEOUGH HAS BEEN appointed health commissioner of Troy

Richmond County

THE STORY OF THE Mayo Brothers Clinic in Rochester, Minn, was told to the members of the Richmond County Medical Society on Nov 10 at the Staten Island Club, St Mark's place, St George, by Dr Jolin J Goller and Dr Lynn Halbert

Dr Goller and Dr Halbert recently went to Rochester for post-graduate work in surgery

Dr Goller, who is on the staff of St Vincent's Hospital, described the early history of the Mayo brothers and their father, Dr William Worell Mayo, who started their clinic in 1863

Dr Halbert, who is on the Staten Island Hospital staff, described the new technics in gastric resection taught at the Mayo Clinic. He used motion pictures and x-ray films to illustrate his lecture

Rockland County

"THE RELATIONSHIP OF SPECIALTIES TO GENERAL MEDICINE" was the subject of a course of lectures delivered to members of the Rockland County Medical Society, Friday afternoons in November, at the Summit Park Sanatorium, Pomona.

Steuben County

A DINNER MEETING OF THE Steuben County Medical Society was held in Bath on Nov 11. The speaker was Dr James Cole

Tompkins County

CORNELL HAS TIGHTENED its health regulations for all students, participating in organized athletics, by putting into effect a rigid set of rules proposed by Dr F F Smuley, medical adviser. The rules, for

athletes competing in varsity, freshmen, or intramural sports, have been adopted by the Board of Athletic Policy

Major features of the rules provide that no student may participate in any form of athletics without first being certified as physically qualified by the medical adviser of the university, team physician, or one of the assistant medical advisers

They also provide for a team physician to care for all injuries received in varsity or freshmen athletics and outline the procedure for taking care of injuries in intramural athletics

No bills for medical service or supplies of any kind will be paid by Cornell's Department of physical education and athletics unless authorized by the director, medical adviser, or team physician

A record of all injuries in all departments will be kept by the team physician and a summary of his records will be submitted annually to the medical adviser and director of physical education and athletics

Warren County

THE GLENS FALLS ACADEMY of Medicine met on Nov 19 in the auditorium of the Crandall Library to hear Dr Louis Hamman of Baltimore, Md, speak on "The Spontaneous Interstitial Emphysema of the Lungs". Dr Hamman is associate professor of clinical medicine at Johns Hopkins Hospital, Baltimore. Members of the Academy entertained the guest speaker at dinner

Westchester County

ADDRESSES BY TWO physicians featured the joint dinner-meeting of the New Rochelle Dental and Medical Societies on Nov 8

Dr H B Wightman, president of the Medical Society, officiated as chairman, introducing Dr W C Carr, oral surgeon at the Metropolitan Hospital, and Dr Edward Hartung, chief of the Arthritis Clinic in the Post Graduate Hospital, New York City

Dr Carr spoke on "The Role of Oral Surgery and its Relation to General Medicine" while Dr Hartung's topic was "Focal Infections and Their Relation to Arthritis". Both speakers illustrated their lectures with lantern slides and a general discussion followed

RECENT ADVANCES in diagnosis and management of acute surgical conditions were discussed by Dr C S B Cassasa, director of surgery at Harlem Hospital and assistant medical examiner of New York City at the 369th meeting of the Mount Vernon Medical Society on Nov 18

Thus far, we have been unable to find a clear-cut, uncontrovertible definition of the status of hospital medical records, as confidential documents, either in the statutory laws or in the decisions of the high courts of this state. This seems almost incredible. Yet I think we have gone into at least the most obvious reference resources

"Here is another important point. During the last two years we have had disputes with certain of the judges in County Courts and in the Supreme Court, in our area. These judges are all learned and highly respected men, yet they are, apparently, not in agreement as to the status of our hospital medical charts. Some of them treat them as confidential documents while others treat them very much as they would books of account, statistics, or what have you. For example, some time ago, we were served with a court order to display the record of an ex-patient to the lawyers of her husband, in preparation for annulment proceedings. Needless to say, we put up strong resistance and offered to make a test case of it. The lawyers for the husband backed down and agreed to have the order vacated. Then again, our records, taken to court in answer to subpoenae duces tecum, have been ordered by some of the judges to be shown to the lawyers before the patient had testified as to his illness or injuries, whereas, other judges do not permit such a practice.

"Thus, we have confusion among lawyers and apparently also among some of the judiciary, regarding the status of medical charts. I need hardly mention that there is plenty of confusion among the hospitals."

A Cardinal Rule of Medical Ethics

This confusion prompts Dr Bowles to "turn to some fundamental principles" As he put it

Let us then turn to some fundamental principles One of the cardinal rules of medical ethics requires a physician to keep in absolute confidence anything he learns about his patient This includes statements made to him by the patient, the things he observes in the patient's home, and everything he learns from physical and laboratory examinations There are a few exceptions to this rule, such as those concerning the reporting of communicable diseases, a patient treated for gun-shot wounds, and death due to unnatural causes, etc However, the exceptions prove the rule

'Unless we had this rule of ethics, medical practice would be well-nigh impossible Patients entrust to physicians information which they won't reveal to even their closest relatives or most intimate friends Unless they can trust the physician to keep this information secret, they would hold back information which might be of paramount importance to the establishment of a correct diagnosis and the administration of correct therapy Everything possible must be done to encourage patients to confide in their physicians As it is, we have to deal with all too many individuals who refuse to tell us the whole truth about themselves and their families It seems *foolish* for them to take this attitude and yet we can see their side of the problem The public in general still attaches a stigma to various diseases The venereal group is an obvious example There are still communities of people who speak of tuberculosis in whispers by the old name "consumption" I am told that there are certain racial groups who still place a taboo on families rumored to have a member with diabetes or cancer or pernicious anemia Apparently, there is no end to the list"

How the Rule Can Be Maintained

The uncertainty that clouds the hospital's right to hold a medical record as confidential and secret under the rule of ethics just mentioned is portrayed as follows by Dr Bowles, who calls upon the Hospital Association and State Medical Society to foster legislation to bring order out of chaos

So far as I know, there is no law which requires a physician to obey this rule of ethics, but the principle is recognized in law in Section 352 of the Civil Practice Act which states as follows

"Physicians and Nurses Not to Disclose Professional Information A person duly authorized to practice physics or surgery or a professional or registered nurse shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity and which was necessary to enable him to act in that capacity, unless, where the patient is a child under the age of sixteen, the information so acquired indicates that the patient has been the victim or subject of a crime, and so forth"

There is a similar Section dealing with the confidential privilege of communications between clients and lawyers A further portion of this law provides that the confidential status of the communication is broken if a third party is present at the time the communication is given There are some exceptions to this rule, but I must admit that I'm not yet quite certain of all of them I *believe* I am correct in stating that one exception permits a lawyer's assistant or his stenographer to be present and not break the confidential privilege of the statements made by the client Yet the argument is advanced that the presence of an intern, or a nurse, or any other hospital worker, when a physician interviews or examines his patient automatically destroys the confidential relationship! Some lawyers have also argued that if a patient allows a record to be kept, knowing that interns or nurses or possibly others (such as medical students, record librarians, social workers, etc.) may be permitted to read it, then no confidential privilege exists! Hence, according to this, patient records are common property

My rebuttal to this type of argument is as follows

1 It is generally recognized that hospitals are absolutely necessary to the successful treatment of many diseases

2 It is necessary for the physician treating patients in a hospital to have the assistance of house staff physicians, of graduate nurses, and nurse helpers (such as attendants, orderlies, etc.), and often social workers These members of the hospital personnel are regarded as direct assistants to the physician and, as such they are obliged to conform to all the rules of medical ethics The hospital must also insist that all of its other personnel refrain from revealing to any one other than the physician or his direct assistants, anything they may happen to learn about the patients, otherwise, patients wouldn't go to hospitals

3 Properly kept medical records are essen-

tial to the safe and efficient care of hospital patients. You are all familiar with this point, I am sure, so I shall not elaborate upon it.

4 Hospitals guard their medical records as confidential documents (or, at least, they should).

Therefore, the presence of hospital employees, when a surgeon converses with, or examines a patient, does not break the confidential relationship, nor does the tacit consent of the patient to the keeping of a medical record destroy that relationship.

When all is said and done, *a hospital medical record is nothing but a privileged confidential communication in written form.* As such, all legal rules which apply to confidential communications between patient and physician should also apply to hospital medical records. *That is what I believe the legal status of medical records should be.*

Within the past year, the Court of Appeals of the State of Missouri has clearly enunciated this principle. This case was abstracted in the *Journal of the American Medical Association*, page 2158, December 26, 1936. There is also a

notation concerning it in *Hospitals*, page 64, January 1937.

As I mentioned before, I have thus far been unable to find that the high courts in this state have ever ruled on this question. Also, if I am correctly informed, the situation is not covered in the Common Law.

It can be further shown that hospital records are of great importance to medical research for improved methods of diagnosing and treating diseases. Therefore, they are of importance to the general welfare of the people and everything possible should be done to make it safe for physicians and hospitals to keep proper medical charts, at the same time protecting the confidential relationships with their patients.

What to do about it? In the first place, I urge that all hospitals cling firmly to the principle that hospital medical records are privileged communications in written form. Second, I suggest that the officers of this Association, in conjunction with the officers of the Medical Society of the State of New York, foster legislative enactments which will properly establish the legal status of hospital medical records.

Improvements

ST MARY'S HOSPITAL, Brooklyn, has been rebuilding during the summer months. A new entrance and roadway have been constructed onto the West wing. A span over the West wing, built as a fire exit, offers opportunity for relief of waiting-room congestion. Wards 1-2 and 3-4, and several semi-private rooms have been reconditioned. The change of location of the chaplain's quarters has made possible the arranging of a new four-bed room and a waiting room for visitors. A private conference room has also been arranged.

THE WYOMING COUNTY Community Hospital has a new maternity wing.

THE WESTCHESTER COUNTY FEDERATION of Women has asked the board of supervisors to provide funds for additional beds in the psychiatric division at Grasslands Hospital at Valhalla, on the plea that "the increase in sex crime throughout the country must be met through psychiatric services," and the facilities at Grasslands are overcrowded.

and comfort are included in plans for the new \$100,000 nurses' home under construction as an adjunct of the Victory Memorial Hospital, New York City. The new structure will have wardrobes and furniture of pressed steel and baked enamel. It will be ready for occupancy in February 1938.

THE \$400,000 MAX AND FLORA EINHORN Memorial Building of the Lenox Hill Hospital, at 131 E 76 St, New York City, was dedicated in the presence of 300 persons, including many physicians and surgeons, in October.

The building is a gift of Dr Max Einhorn, noted gastroenterologist, who has been associated with the hospital for more than fifty years. It includes a twenty-five-bed pavilion, an auditorium, a roof garden, a hydrotherapy department, and a swimming pool.

MAYOR LAGUARDIA, in a statement says that Dr S S Goldwater, Commissioner of Hospitals, is justified in pressing for the erection of the Triboro Tuberculosis Hospital on the grounds of the Queens General Hospital in Flushing-Hillcrest. The mayor stated

"Even if the city were to benefit from the State's new program—and there is no reason why it should not get its share in the tubercular hospital program—these two hospitals, the Triboro and the Riverside on North Brother's Island would still be needed"

THE CONSTRUCTION OF A modern addition to Memorial hospital in Buffalo is being considered, it is announced by Charles Duchmann, 65, who for forty-one years has been superintendent of the institution founded that many years ago as the German hospital

Newsy Notes

A DISPATCH FROM NEW HAVEN says that the "hot money" changers are now using babies in their flim-flam, but neither the babies nor their mothers know it. Local hospital cashiers have been stuck for \$100 each by a smooth gentleman who calls at the office and smilingly confides that he is "going upstairs to leave a little present for Baby Blank," and asks to have five rumpled \$20 bills changed for newer ones.

It doesn't take the cashier long to discover that the rumpled bills are counterfeit, but the gift-bringer is nowhere to be found. In each case the name of a baby or mother actually in the hospital was used, and the supposition is that the counterfeit-passer consulted the birth-columns of the local papers for his information.

ST JOHN'S UNIVERSITY School of Pharmacy, Brooklyn, began a new course in hospital pharmacy with the opening of the school year. Morris Dauer, PhG, BSc, chief pharmacist of King's County Hospital, City of New York, department of hospitals, and chairman of the committee on hospital public service pharmacies of the New York Pharmaceutical Association, is the instructor. Because of the high type of skill and training that a hospital pharmacist must possess, it is understood that the qualifications demanded can best be instilled only at a college or a school of pharmacy by a professor or educator who has had personal contact and experience in the field of hospital pharmacy.

THE PROBLEM of rehabilitating tuberculosis convalescents discharged from Grasslands Hospital but not yet ready to resume their normal place in the community, was presented to New Rochelle, on Nov. 8 at the home of Mrs. William H. Lough who has succeeded her husband on the

Board of Directors of the Westchester County Tuberculosis Association.

The meeting, attended by representatives of agencies dealing with the patients and convalescents, stressed the need for an organized program of rehabilitation, with establishment of a workshop, a major part already underway.

There are more than twenty convalescents in boarding homes throughout New Rochelle, it was pointed out, with many eager to find some means of making money and starting back on the road to self-support.

Difficulties to be met, it was pointed out, are the change from the organized life at Grasslands to one in a boarding home, the physical inability of the convalescents to do full-time work, the breaking down of their morale and their lack of equipment to begin life again.

MAYOR LA GUARDIA says in a statement that although New York city pays about sixty-eight per cent of the cost of maintaining hospitals upstate, the city receives little or nothing for its own hospitals from the state. The mayor expressed the hope that the city would receive its fair share of the \$40,000,000 bond issue for hospitals authorized by the electorate on November 2.

MR. FREDERICK A. SHARPE, the new executive director of the White Plains Hospital, has made public the results of a study showing that the hospital is overcrowded. "It amply justifies the judgment of the board regarding the soundness of the building program adopted a year and a half ago," he says.

THE ANNUAL DINNER AND DANCE of the

Beth El Hospital in Brooklyn in November netted \$25,000 to apply on its deficit. Tickets were \$100 a couple

IN THE LAST YEAR the junior auxiliary made over 8000 articles for the Peekskill Hospital

AS THE RESULT OF OVERCROWDED conditions in New York State institutions, 150 mentally defective persons in Brooklyn alone are free to associate with the public while awaiting commitment to a state school. This fact was revealed recently in testimony before the legislative committee investigating sex crimes. Although the need for commitments was reported as urgent, the two institutions available to the city, Letchworth Village and the Wassaic State School, could not care for all the feeble-minded.

Dr Gladys McDermid, alienist in the mental hygiene clinic of Kings County Hospital, told the committee that admissions to Letchworth Village and Wassaic had been closed except during a few intervals, for the last two or three years. She pointed out that an institution was needed nearby to handle emergency cases.

THE STAFF OF BAY RIDGE Hospital celebrated the twenty-fifth anniversary of its founding with a jubilee dinner at the Hotel Towers, Brooklyn, on October 30. The keynote of the celebration was the unusual success attained by this hospital, which is owned, managed and conducted by doctors. It started modestly in 1912, when five Brooklyn physicians, faced with a shortage of convenient hospital facilities, borrowed \$6,000 and leased the property at 437 Ovington Ave. And now it is a \$400,000 institution,

with modern equipment, although it has never received one dollar in endowment from any source. From the very start it was a success and all the profits were spent in expansion and improvements. Its maternity ward has delivered 5,000 babies and in the last four years there was not a single maternity death.

Although as a private hospital it has cared for some 37,000 bed patients, with the cooperation of the medical staff many deserving patients, emergency and accident cases, have been cared for free of charge. The need for medical charity is so great that the officers are considering an endowment drive.

Dr Carl H. Mayne, who is president of Dr Henry F. Bruning, vice president, and Dr John P. McQuillin, the treasurer, were among the five doctors who started the hospital twenty-five years ago. The other two were Drs Benjamin Kopf and Roderick Byington. Dr Edmund O. Darbois is secretary and Mrs Gertrude E. Mathewson is superintendent.

TWINS WERE born on October 18 at the McCarty Hospital in Saratoga Springs—the first that institution has seen since Dr Richard H. McCarty advertised thirty years ago that he would award \$100 to the mother of the first twins born there. In 1907, Dr McCarty, owner of the hospital, inserted his advertisement in a local paper. Triplets have been born at the hospital and Dr McCarty has delivered eleven sets of twins at the parents' homes since that time. But not until now did any one claim the award. Twins, a boy and girl, were born at the hospital to Mr and Mrs Kirtland Woodcock of Saratoga, October 18. Dr McCarty presented Mrs Woodcock \$100 and also gave \$25 to each of the twins. Mrs Woodcock was at one time employed at the hospital.

At the Helm

THESE HOSPITAL OFFICIALS HAVE BEEN CHOSEN
Dr C. Harvey Jewett, to be president of the F. F. Thompson Memorial staff physicians at Canandaigua
Dr Clare N. Shumway, to be president of the medical staff of Corning Hospital

Dr Harry J. Worthing, to be head of the Pilgrim State Hospital at Brentwood, L. I.
Dr Johnston MacLeod, to be chief of the medical division of Flushing Hospital
Mrs Hubert J. Treacy, to be president of the Ladies Aid Society of St. Joseph's Hospital at Far Rockaway

LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Treatment of Injuries Sustained in Automobile Accident

A doctor who specialized in orthopedic surgery was called to a hospital to attend a young woman who had injured her arm in an automobile accident. He found that she was suffering from a comminuted fracture of the lower third of the left humerus, for which she had already received first aid treatment. He undertook to reduce the fracture and applied traction suspension with pulley and weights, holding the fragments of the arm in position and leaving the arm joints movable within proper limits.

The following day the doctor found that blebs had developed all around the lower half of the left arm, including the area that was covered with adhesive, so he removed the arm from the suspension apparatus and with the use of a fluoroscope applied a plaster cast. X-ray pictures taken both before and after the cast was applied, indicated that a good alignment of the fragments was obtained.

Within a few days the patient returned to her home and at a subsequent date an X-ray revealed that the fragments of bone had slipped away from their proper position so the cast was removed and further adjustments were made by the doctor. Another cast was applied after such treatment. The doctor continued to care for the case and in three months he found firm union and the patient began to have satisfactory restoration of function. The patient returned to his office for diathermy treatments from time to time and when he decided that her condition was satisfactory he discharged her. Her condition then seemed extremely good considering the type of injury involved.

Shortly thereafter the physician was called as a witness for the patient in a lawsuit which she had instituted against the person who was claimed to be responsible for the original automobile accident. He testified to the nature of the injuries and with respect to the treatment that he had rendered. A fairly substantial verdict was rendered in favor of the patient (plaintiff in the automobile case). Thereafter the doctor instituted an action in the Supreme Court to recover his fee for professional services and a counterclaim charging him

with malpractice, was interposed. As a special defense to the charges of malpractice there was set up in the pleadings the fact that the accident case had resulted in payment of a substantial sum of money to the doctor's patient, upon the theory that the said payment, subsequent to the treatment rendered by the physician, extinguished any possible claim that the patient might have had against him based upon alleged malpractice.

The case came up for trial. It was a non-jury case and in the course of the trial a conference with the presiding judge resulted in a dismissal of the counterclaim and a settlement of the doctor's bill for services.

Failure to Diagnose Dislocation of Wrist

A young married woman consulted a physician engaged in general practice, with respect to complaints of pain in the right wrist. She told the doctor that her car had collided with a hydrant the day before and she had sustained her injuries in such manner.

Examination of the wrist showed that it was swollen but manipulation failed to indicate the presence of any fracture. The doctor diagnosed the condition as a sprain. He applied a splint and directed the patient to apply cold dressings and return to him later on. When she did return, about two weeks later, he removed the splint, examined the wrist, saw the swelling had gone down considerably, and reapplied the splint and advised her to return about two weeks later. On that occasion the wrist was still swollen and a partial splint was reapplied and she was told to return again. When she finally returned, upon removal of the splint the doctor found the patient suffering from a silver-fork deformity of the wrist and he told her it was necessary to have an X-ray taken immediately. She never returned to the doctor for treatment. He later learned that she had gone to another physician and that X-rays had revealed a dislocation of the wrist, which was eventually reduced by open reduction. Approximately two and one-half years after the doctor last saw the patient a mal-

practice action was instituted against him in the Supreme Court, charging him with failure to detect the true nature of the injuries. An application was made to the Court for the purpose of obtaining a dismissal of the complaint on the grounds that this action was barred by the two year statute of limitations, controlling malpractice actions.

The said motion was duly granted and judgment entered dismissing the complaint thereby finally terminating the action brought against the physician.

Incision of Fistula

A man thirty-five years of age consulted a physician who specialized in the treatment of rectal diseases. Upon examination it was found that he was suffering from a left anterior incomplete external fistula which had an external opening but no internal opening. An operation was consented to and under a local anesthetic of

novocaine the doctor incised the fistulous tract, making an inverted T shaped incision. The patient remained in the hospital four days and left in good condition. He returned to the doctor's office periodically for treatments and about six weeks later an infection developed at the site of the incision. The doctor treated the infection, which was slow in clearing, and when he last saw the patient about four months after the operation the wound was almost healed.

An action was brought against the physician, based upon alleged malpractice, and upon the further charge that the defendant had guaranteed to cure within a short period of time.

Shortly before the case was about to be reached for trial the plaintiff's attorney or record died. The patient, himself an attorney, thereupon undertook to negotiate for a settlement of the case and when no offer was made on behalf of the defendant he finally agreed to discontinue the action.

DIAGNOSIS OF INFECTIOUS MONONUCLEOSIS

Infectious mononucleosis occurs chiefly as a sporadic disease of young adults, epidemics are rare. Glandular fever is a similar but probably different disease affecting children, epidemic outbreaks are not infrequent. Typical cases of infectious mononucleosis are characterized by fever, malaise, weakness, vomiting or nausea, enlarged and tender cervical or other groups of lymph nodes. Occasionally lymphadenitis is not observed. Sore throat and abdominal pain frequently occur. A diagnosis is established by the symptoms, a relative increase of large mononuclear cells in the blood—many of which are probably abnormal lymphocytes—and the demonstration of agglutinative properties for sheep red blood cells in the serum of the patient. Since the etiology of the disease is unknown, bacteriological studies are of no assistance except to exclude other infections. Although the acute attack is usually short, convalescence may be prolonged, in some cases extending over a period of several months. In its early stages the disease may be difficult to distinguish from acute lymphatic leukemia, but in the latter the patient's serum does not contain agglutinins for sheep red blood cells. The prognosis is always good.

Laboratory Findings

I Blood Count The blood picture is very

characteristic but not absolutely specific. Usually the total white blood cell count is between 12,000 and 20,000, occasionally there is a leukopenia, more than 50 per cent of the white blood cells are lymphocytes, many of which are of a type not normally found in the peripheral blood.

II Serological Test The blood of most patients with infectious mononucleosis agglutinates sheep red blood cells. From five to ten c.c. of blood should be collected for the test. As is true in other diseases, these serological properties may not be demonstrated until a week or more after onset of symptoms. Also, the titer of the reaction has been found to diminish rapidly following recovery. In a consideration of the significance of agglutinative properties for sheep red blood cells, it should be borne in mind that the blood of patients who have been injected with horse serum or certain other types of protein may also agglutinate sheep erythrocytes. The serum from children with glandular fever usually does not contain agglutinins for sheep red blood cells.

Although the incidence of infectious mononucleosis is relatively low in New York State, the disease is evidently more prevalent than is generally appreciated—Issued by The New York State Association of Public Health Laboratories, Leaflet No 9

Across the Desk

"He that Hath Ears to Hear, Let him Hear"

WHEN MARK ANTONY ASKED his friends, Romans and countrymen to lend him their ears, he may not have realized that the loan, in many cases, would be as bootless as a defaulted bond issue, and that his sweetest notes would go to protest. Strangely enough, we are only finding out in this year of grace 1937 how large a fraction of the population are hearing but imperfectly what their ears were intended to hear "Ears have they, but they hear not"

The investigation that is uncovering this serious state of affairs is beginning at the right spot—in the schools. It is already estimated that 3,000,000 school children have a demonstrable deficiency of hearing, causing a recognized or potential handicap, with unknown millions more among the adult population. Here is not a new field, perhaps, where the medical profession can be of vital help, but certainly a field where the vast extent has never been appreciated, a field to keep both the specialist and the family doctor working overtime.

Get the Picture Right

We shall fail, too, to see the true picture if we merely feel a pang of sorrow over the poor little child who cannot hear the birds sing, the band play, or the radio dispense the humor of Amos 'n' Andy or Pop-Eye the Sailor. The child's plight is far worse than that, especially when the defect is so small that nobody has recognized it. A slight deafness, in fact, carries heavy disadvantages just because it is unrealized. The victim has never known normal hearing, and believes he hears the same as everybody else, while the parents, teachers, and playmates, instead of thinking him deaf, call him "dumb." He only gets credit for stupidity. All the oral instruction, the teacher's questions, the class discussion, are muffled and indistinct. Repeatedly called a fool and blockhead, he finally accepts the description as true, forms a permanent inferiority complex, stops trying to do much or be much, and becomes a human liability, instead of an asset. In an investigation in Omaha, only thirty-seven per cent of the

parents knew their children had a hearing deficiency until advised by the school nurse.

Even when the child's deafness is recognized, an equally deplorable situation is sometimes produced by the defeatist attitude of the family, "the widespread, persistent, cruel fallacy to the effect that when once the ear has begun to deteriorate, treatment is not worth while—this defeatist attitude has caused much needless deafness," as a speaker said at the AMA meeting in June.

Yet few states are doing anything to meet this situation. More than ten years have gone by since the House of Delegates of the AMA in 1926 adopted a resolution endorsing the regular, periodic testing of all school children by scientifically accurate methods. This was followed by similar action by many other national and state medical organizations. It was not until last year, however, that the New York legislature passed a law making the audiometric testing of all school children mandatory. It was also required that all school children in the state having a loss of hearing be reported by the attending physician, nurse, or other person responsible, through the local health officer, to the state health department. This year a law created a temporary commission to study hearing conditions among pre-school and school children.

Spot the Little Defects in Time to Help

The old-fashioned methods of testing the ear have been found inadequate, it seems. What is now used is the audiometer, which will test the hearing of as many as forty pupils at once in a few minutes. This device reveals three or four times as many pupils with hearing defects as were found by the older methods, said Dr. Horace Newhart, of Minneapolis, at the AMA convention in June, while Dr. Claude T. Uren, of Omaha, reports that "about ten times as many children with hearing defects are picked up with this method as were found with less scientific methods." The discov-

ery of the little defects permits treatment before they grow too serious and deep-seated for successful correction. Dr. Uren found that about fifty per cent of the children with impaired hearing needed tonsil and adenoid operations, which might not otherwise have been discovered. In his investigation the children with hearing defects ran from 60 to 140 per 1000, depending upon locality. In Minneapolis, ten years ago, eight per cent of the school children showed hearing defects in the audiometer tests—now it has been reduced to 53 per cent. In Cincinnati, according to Dr. Leo S. Friedman, quoted in the *AMA Journal*, "about 12,000 hearing tests are carried out each year, which reveal about 900 children with hearing defects. Of this number, 500 are referred to private physicians and the remainder to a well organized clinic under the guidance of experienced workers. The latest reports indicate that approximately 52 per cent of these defects have been corrected."

New York City's Huge Investigation of 1,500,000 Ears

By far the largest investigation has been, and still is, going on in New York City as "WPA Project 6065 for the Conservation of Hearing of School Children," under the direction of Daniel Caplin, Assistant Director of Health Education of the city Board of Education. Over 770,000 children have been tested, of whom 30,000 had impairments in both ears, 36,000 had impairments in the right ear, and 34,000 in the left ear. Over 75,000 had active histories of running ears, earaches, etc. In this investigation the pupils are tested in groups of eight to forty with the audiometer, then a second test with the same device is given to all who show a slight deficiency. Those below normal in both tests receive individual tests with the audiometer, which tests hearing acuity for both air and bone conduction in speech and complete tone ranges. A detailed history of health, educational progress, etc., is taken. Investigators and nurses arrange for otological examinations, assist the otologist, and visit the homes to see that his advice is carried out. In addition to the examination by an otologist in the school, the project also calls for referral to private doctors and clinics for

treatment and investigation. An effort is made to have a second otological examination and confirmation for each child. The plan, not only in New York, but in all cities making these inquiries, is to have repeated examinations throughout the school course, so that defects will be discovered in time for early and effective treatment.

How the Little Ears are Helped

Nor is this all. The pupils who hear poorly are, for one thing, given front seats, and the teachers make a special effort to speak clearly and distinctly to them. Then if the loss of hearing is more than twenty decibels in the better ear, they have special instruction in lip-reading, and, if badly deafened, they are put in a special class for the hard of hearing in a residential or day school, temporarily, until their skill in lip reading and voice training permits a return to their old class and school friends. The use of modern individual and group hearing devices is a great help, Dr. Newhart declares, to the child having a loss of hearing of forty decibels or more in the better ear if, on thorough trial, it materially increases his ability to interpret articulate speech. Indeed, he declares, "all children of kindergarten age or older having a defect which can be materially compensated by a hearing device should be given the benefit of such an aid. The use of a hearing device by the child with a handicapping loss of hearing will in the near future probably be as common as is the use of corrective glasses by the child with a visual defect causing an equal handicap."

Dr. Edmund Prince Fowler, in charge of the medical aspects of the survey of the hearing of the New York school children, also recommends mechanical aids when needed, and he adds shrewdly, "It is well to consult a specialist before buying one."

A note in these pages a year or so ago told of the efforts of the British Medical Association against unscrupulous makers of hearing aids who were exploiting the deaf and persuading them to buy devices, regardless of their cause of deafness, which turned out worthless. Hence the insistence by the investigators here on competent medical advice from start to

finish A recent newspaper advertisement in this country proclaimed in large type "DEAFNESS DEADLIER THAN CANCER Cancer means certain death unless caught in time Deafness steadily but surely progresses to the living death—stone deafness—unless caught in time" Comment on such advertising is unnecessary

All the splendid work, going and growing, for the bewildered school-child trying

to live in a half-realized world, makes one only wonder why it was not done long ago It recalls the passage in the Book of Proverbs "The hearing ear, and the seeing eye, the Lord hath made even both of them" If this be so, then is it not true that there is something that partakes of the godlike and divine in restoring these delicate organs, when they are impaired, to the usefulness for which they were intended?

Books

Books for review should be sent to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N Y Acknowledgment of receipt will be made in these columns and deemed sufficient notification Selection for review will be based on merit and the interest to our readers

Tweedy's Practical Obstetrics Revised and largely rewritten by Bethel Solomons, M D and Ninian McIntire Falkner, M D Seventh edition Octavo of 773 pages, illustrated New York, Oxford University Press, 1937 Cloth, \$8.75

This textbook by the late Master of the Rotunda and his assistant, has been planned for the general practitioner It is comprehensive, yet not too full nor discursive It is particularly interesting to specialists as an exposition of the Dublin practice Considerable space is devoted to the newborn infant

Solomons calls wearing of masks a fetish, gauze without cellophane is useless and dangerous Vaginal and rectal examinations are rarely made, external vaginal examinations, in which descent is appreciated by a finger between annus and coccyx with pressure from above, are very valuable Nitrous oxid anesthesia is used very little on account of expense Perineorrhaphy is done with the patient on her side, using number two or three catgut.

Caesarean is rarely performed for accidental hemorrhage, and the low transverse Kerr incision, so popular there, is no longer used for previa, where classical section is preferred, using number four silk for suture

For posterior occiput and breech prolonged expectancy is advised, and forceps on the aftercoming head are not mentioned Kielland forceps are not liked, and, for the most part, pelvic applications of the forceps are thought to be as good as cephalic Pubiotomy and induction of labor in the borderline pelvis are still advocated, and

pelvimetry by Skutsch's pelvimeter is thought to be perfectly satisfactory

CHARLES A GORDON

Textbook of Diagnostic Roentgenology By Lewis J Friedman, M D Quarto of 623 pages, illustrated New York, D Appleton-Century Company, 1937 Cloth, \$10.00

The author has accomplished a Herculean task in covering in an adequate manner the field of Diagnostic Roentgenology in a single volume From fundamental Roentgen physics to the most intricate of diagnostic problems, the reader is carried on through a volume in which each division and chapter bespeaks of careful planning and gathering of material The latter, being accumulated from one of the most prolific sources of pathology in the world, has been beautifully reproduced and labelled In addition, the legend accompanying each reproduction saves the reader much time, as there is no necessity to scan pages of reading matter to grasp the author's thought.

The volume is recommended to the beginner who wishes to actually study it as a text, or to the more experienced as a reference book A perusal of any of the chapters is stimulating, the author enhancing its readability by diction which is comparable to some of the best medical literature the reviewer has ever encountered It is especially recommended to all roentgenologists, and also to our confreres, as the author spares no pains in emphasizing the necessity for closer cooperation from the clinician to procure the most satisfactory Roentgen interpretation

GEORGE W CRAMP

ORDERING BOOKS

As a service exclusive to our readers, books published in this country may be ordered through the Business and Editorial Offices of the Journal (33 W 42nd St N Y C) postage prepaid Order must be accompanied by remittance covering published price

Index—Vol. 37, 1937

Scientific Articles

- Accidental Smallpox Vaccination and Eczema Vaccinatum—Graves, Dowman 1833
 Acne Vulgaris, Therapy of, With Hormone Preparations—Rosenthal 244
 Adenomata—Relation to Rectocolonic Carcinoma—Yeomans 390
 Adrenalectomy, Partial, (Bilateral)—For Malignant Hypertension—Freidman, Eisenberg 1131
 Adrenals, Adenoma, Adenocarcinoma of—Based on a Series of 34 Cases—Feinblatt, Alpert 861
 Allergy in Drug Eruptions, Role of—Abramowitz 128
 Allergy, Little Recognized Types of—Clarke 236
 Anal Abscess and Anal Fistula—Etiology and Treatment—Brust 400
 An Attachment for use in Conjunction with the Scalpel—Akl 1293
 And It Ever Will be Said of Youth—Wile 960
 Angina Pectoris in Senility—Foti 2018
 Aorta, Coarctation of the—With Report of a Living Case—Gutlow 155
 Appendix, Carcinoid of—Ruptured Ovarian Cyst—Lebovitz 1433
 Aspiration of Wooden Tongue Depressor—Followed by Purulent Pneumonitis Case 59
 Report—Schugt 2013
 Asthma Bronchial—Review of One Hundred Cases Treated at the New York Post-graduate Medical School and Hospital—Mamelok 253
 Bacillary Dysentery, Pneumonic Type—Felsen 643
 Breasts, Pendulous and Hypertrophied—The Operative Treatment—Dowkontt 169
 Buergli's Theory—Applied to the Treatment of Secondary Anemia—Almour 141
 Bundle Branch Block—Diagnosis By Physical Signs—Gray 175
 Cancer Group, The Aims of a—Howes 2065
 Cancer of the Breast—Present Status of Surgery and Irradiation Therapy—Adair 1095
 Cancer of the Rectum and Rectosigmoid—Notes on Surgical Treatment—Rankin 296
 Cardiac and Respiratory Disease, Recent Advances in Inhalation Therapy in the Treatment—Principles and Methods—Barach 934
 Central Retinal Artery, Acute Obstruction of—Relieved by Intravenous Sodium Nitrate—Esterman 543
 Cerebral Apoplexy—Two Recoveries Following Surgical Intervention—Kaplan 1619
 Cesarean Section—Quigley 249
 Cirrhosis, Histogenesis of Laennec's—Hart, Lisa 569
 Clitocybe Dealbata, Some Notes on Poisoning by—Jelliffe 1025
 Colitis, Ulcerative Bacteriological Aspects—Frakin 857
 Colles' Fractures, Treatment of—Johnson 1049
 Colloidal Sulphur, Clinical Experience with—In Treating Mixed and Hypertrophic Arthritis—Clark 1707
 Colon Bacillus Chemical Therapy—Degenerative Processes—Coburn 1638
 Colon, Carcinoma of the—MacGuire 1995
 Comments by a Country Doctor—Time 1893-1933—Allen 865
 Coronary Artery Thrombosis—Mode of Death and Analysis of Fatal Cases—Master, Dack, Jaffe 939
 Coronary Thrombosis—Relationship to Thromboangitis Obliterans—Sclar 1362
 Council on Physical Therapy Investigation of Apparatus by the—Carter 1733
 Cystitis, Chronic Alkaline Encrusted—Cure of Case with Contraction of Bladder by Vitamin A Regime and Indwelling Catheter—Frumkin 636
 Cystitis Gangrenous—Townsend 1577
 Cystoscopy Nontraumatic—Clark 1671
 Dental Caries in Children—Clinical Control—Kugelmass 21
 Diabetes Mellitus—Factors Influencing Cause Course, and Complications—Analysis of 88 Cases—Tuttle 847
 Diabetes Mellitus—Impotent Insulin a Factor in Supposed Insulin Fast Diabetes—Report of a Case—Feinblatt, Ferguson 1997
 Diabetes Mellitus—Short Wave Diathermy and Office Surgery—Ratzan 152
 Dietary, Proper As a Public Health Measure—Relation to Infancy and Childhood—Wynkoop 2082
 Drug Therapy Chaos in—A Vicious Circle—Solomon 645
 Duodenum—Roentgenologically Considered and Including One Case of Primary Carcinoma—Howes 406
 Dysphagia of Esophageal Origin, Roentgenological Consideration of—Barnes 1271
 Electromyography, Clinical—A Preliminary Study of Normal and Ischemic Muscles—Jablons Reichert 1842
 Empyema Surgical Treatment of—Greevey 2135
 Endocrine Disturbances Simulating Surgical Conditions of the Abdomen—Lester 2135
 Endocrines—Relation to Blood Disorders—Reich 2135
 Enterococcus Endocarditis—Clements 2135

Epileptic School Child—How May We Understand and Treat Him?—Patry	1553
Erythrocyte Sedimentation Rate—Diagnostic Value in Thyroid Disease—Clinical Observation and Survey of the Literature—Moolten, Goodman	1720
Esophageal Obstruction—Seventy Eight Hospital Cases—Sundc	1197
Esophageal Perforations—With Report of Two Cases—Miller	2093
Extensive Plexiform Neuroma of Neck—Meyer	403
Facial Bones—Treatment of Fractures—Cox	52
Fibula, Rotated — Kirschenmann	1731
Fractures of the Lower Extremities, Compound—With Special Reference to Osteomyelitis and Amputations — Carlucci	2006
Gall-Bladder and Biliary Ducts, Acute Inflammation of the—Douglas	1119
Gall-Bladder Disease, Practical Aspects of—Twiss	1371
Gastric Roentgenologic Changes in Deficiency Disease—Response to Treatment—MacDonald, Hocker, May	1423
Glomerular Nephritis, Chronic Diffuse—Diagnosis, Symptoms, and Treatment—Mosenthal	268
Gonorrhea, Cutaneous Eruptions in—Levin, Silvers	1712
Granulocytopenia—Analysis of Nineteen Cases—Scott, Herbert	38
Hay Fever, Non-Pollen Inhalants in—A Study of Their Part in Its Symptomatology—Berkoff	1499
Head Injuries, Some Problems in—Schuck	1380
Head Injury, The Sequelae of—Strauss, Savitsky	1181
Hernia, Injection Treatment of—Coley	1726
Hernia, Traumatic — Davis	1128
Hodgkin's Disease with Bone Manifestations—Schenk	27
Hyperglycemia, Psychic States Associated with—Boudreau	1627
Hyperthyroidism in Children—Beilby, McClintock	563
Hypoparathyroidism with Pregnancy—Baumgartner, Cowles	1668
Ileostomy in Fulminating Ulcerative Colitis—Subsequent Closure and Recovery—Barney Brust	1852
Immune Serum and Prontosil—Combined Treatment for Protection of the Mouse Against Fatal Dose of Hemophilus Influenzae Meningitis—Preliminary Report—Povitsky	1748
Infiltration Anesthesia in Vaginal Plastic Operations—Matthews, Mazzola	1
Injuries and Infections—A Study of Cases Occurring On The W P A Projects of the Pelham Bay Area—Lowens	1042
Iodized Oil Technic in Pterygium Cases—Dimitry	719
Jaundice, Diagnosis of Surgical—Ottenberg, Colp	1011
Jaundice — Heyd	841
Juvenile Diabetes in Labor—Treated with Crystalline Insulin, Case Report—Alpert, Ferguson	1667
Kidney, The Polycystic—With Special Reference to Complications & Treatment—Lazarus	1565
Labor, Management of Complicated by Rectal Stricture—With a Report of Eighteen Cases—Kassebohm, Schreiber	481
Laryngeal Tuberculosis, Present Status of—A Review of 245 Cases—Frank, Wolf	1652
Lead Poisoning in the Community—From the Standpoint of the Industrial Worker—Gray, Greenfield	1971
Lymphogranuloma Venereum—Report of a Case—Kornblith	488
Maternal Mortality in Erie County, N Y—Report of a Survey By the Maternal Mortality Survey Committee of the Erie County Medical Society—Israel	1479
Medical Survey, Twelve Year, of a Large Commercial Organization—Carter, Westcott	162
Melanoblastosis of the Meninges Primary—Shapiro, Kellert	2096
Meningococcemia—Treatment with Sulfanilamide and Prontosil—Report of Two Cases—Zendel, Greenberg	1744
Meningococcemia Without Meningitis—Report of a Case—Goundry Phalen	491
Mental Hygiene Its Importance to You—Patry	957
Methemoglobinemia and Prontylin—Stoness	1139
Methods of Admission and Discharge in N Y State Hospitals—Pollack	1375
Milk Digestion—Mechanism and Modification—Kugelmass	652
Mongolism Occurring in American Indians—Report of Three Cases—Sirkin	167
Monilia Albicans, Infections of the Skin—1 Diagnostic Value of Intradermal Testing with Commercial Extract of Monilia Albicans—Lewis, Hopper Montgomery	878
Mosaic Wart—An Unusual Type of Plantar Wart—A Montgomery, R. Montgomery	1978
Muscle Injuries—Henson	378
Muscular Dystrophy—Report of a Family—Arbuse, Sloane	1111
Muscular Dystrophy, Progressive—A Biochemical Endocrine Study—Berman	1191
Nasal Deformities, Correction of—Cinelli	1018
Nasal Sinuses, Conservative Treatment of—Hays	137
Newborn, Trauma in the—Hartshorn	869
Noma — Bonafede	1511

Non-Penetrating Wound of the Heart—Injury to the Pericardium and the Left Pericardophrenic Artery With Near Fatal Hemorrhage—Case Report—Levy	1442
Normal Thyroid and Testicular Tissue, Effects of So-Called Ensols on—Pommerenke	1575
Nutritional Regimen, Pre- and Postoperative—A Proposed Five Point Schema—Bridges	2009
Nutritional Reviews I—Protein Requirements—Pollack, Dolger	633
Nutritional Reviews, II—Caloric Requirements—Pollack, Dolger	949
Obstetrics, Trends in—Mellor	1763
Orbital Infections Due to Nasal Sinusitis—A Study of 114 Cases—Hubert	1559
Pain, Psychic Factors in—Casamajor	1984
Pain, Relief of, by Physical Measures—Kovacs	2070
Pathologist, Role of the, in the Non-Teaching Hospital—Curphey	64
Peptic Ulcer, The Acid Factor in—With Special Reference to Milk Drip Therapy and Partial Gastrectomy—Winkelstein	1989
Perforated Duodenal Ulcer Coexistent with Acute Appendicitis—Case Report—Emerson	955
Peripheral Vascular Disease—Simple External Suction—Tenopyr, Shafiroff	1387
Petrositis, Differentiation Between Receding and Progressing Cases of—Almour	1495
Petrous Pyramid, Suppuration of the Pneumatic Antelabyrinthine Portion—Taylor	231
Pharmacopeia, The New—Coleman	1643
